Mix the Fluid Extract with the Alcohol, Glycerin, and *five hundred* (500) *cubic centimeters* of Aromatic Elixir. Incorporate the Magnesium Carbonate thoroughly with the mixture by trituration. Then filter through a wetted filter, and pass enough Aromatic Elixir through the filter to make *one thousand* (1000) *cubic centimeters*.

Each fluidrachm represents about 9½ *grains of Turnera.*

113. ELIXIR VIBURNI OPULI COMPOSITUM. *N. F.*

Compound Elixir of Viburnum Opulus.

Compound Elixir of Crampbark.

Fluid Extract of Viburnum Opulus (U. S. P.)	75 Cc.
Fluid Extract of Trillium (F. 177)	150 Cc.
Fluid Extract of Aletris (F. 137)	75 Cc.
Compound Elixir of Taraxacum (F. 111)	700 Cc.

Mix them. Allow the mixture to stand a few days, if convenient, and filter.

114. ELIXIR VIBURNI PRUNIFOLII. *N. F.*

Elixir of Viburnum Prunifolium.

Elixir of Black Haw.

Fluid Extract of Viburnum Prunifolium (U. S. P.)	125 Cc.
Compound Tincture of Cardamom (U. S. P.)	75 Cc.
Aromatic Elixir (U. S. P.)	800 Cc.

Mix them. Allow the mixture to stand a few days, if convenient, and filter.

Each fluidrachm represents about 7½ *grains of Viburnum Prunifolium.*

115. ELIXIR ZINCI VALERIANATIS. *N. F.*

Elixir of Zinc Valerianate.

Zinc Valerianate	17.5 Gm.
Stronger Solution of Ammonium Citrate (F. 210)	100 Cc.
Alcohol	125 Cc.
Spirit of Bitter Almond (U. S. P.)	10 Cc.
Compound Tincture of Cudbear (F. 419)	15 Cc.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Mix the Stronger Solution of Ammonium Citrate with *two hundred and fifty* (250) *cubic centimeters* of Aromatic Elixir and the Alcohol, and triturate the Zinc Valerianate with this mixture, added gradually and in portions, until solution has been effected. Then add the Spirit of Bitter Almond, the Compound Tincture of Cudbear, and finally, enough Aromatic Elixir to make *one thousand*

(1000) *cubic centimeters.* Allow the mixture to stand a few days, and filter.

Each fluidrachm contains 1 *grain of Zinc Valerianate.*

116. EMPLASTRUM AMMONIACI. *N. F.*

(U. S. P., 1880.)

Ammoniac Plaster.

Ammoniac	100 Gm.
Diluted Acetic Acid	140 Cc.

Digest the Ammoniac with the Diluted Acetic Acid, in a suitable vessel, avoiding contact with metals, until it is entirely emulsionized; then strain and evaporate the strained liquid, by means of a water-bath, stirring constantly, until a small portion, taken from the vessel, hardens on cooling.

117. EMPLASTRUM AROMATICUM. *N. F.*

Aromatic Plaster.

Spice Plaster.

Cloves	10 Gm.
Cinnamon, Saigon	10 Gm.
Ginger	10 Gm.
Capsicum	5 Gm.
Camphor	5 Gm.
Cotton-Seed Oil	35 Gm.
Lead Plaster	25 Gm.

Melt together the Lead Plaster and Cotton-Seed Oil, with the aid of heat. Cool the mixture and, while it is still soft, thoroughly incorporate with it the aromatic ingredients, previously reduced to a very fine powder.

118. EMPLASTRUM ASAFŒTIDÆ. *N. F.*

(U. S. P., 1880.)

Asafetida Plaster.

Asafetida	35 Gm.
Lead Plaster	35 Gm.
Galbanum	15 Gm.
Yellow Wax	15 Gm.
Alcohol	120 Cc.

Digest the Asafetida and Galbanum with the Alcohol on a water-bath, separate the liquid portion, while hot, from the coarser impurities by straining, and evaporate it to the consistence of honey; then add the Lead Plaster and the Wax, previously melted together, stir the mixture well, and evaporate to the proper consistence.

119. EMPLASTRUM FUSCUM CAMPHORATUM. *N. F.*

Camphorated Brown Plaster.

Emplastrum Matris Camphoratum; Camphorated Mother Plaster.

Red Oxide of Lead	300 Gm.
Olive Oil	600 Gm.
Yellow Wax	150 Gm.
Camphor	10 Gm.

Triturate the Red Oxide of Lead with a portion of the Oil in a capacious copper kettle until a smooth paste results. Then add the remainder of the Oil, excepting a small quantity required for trituration with the Camphor, and boil the whole over a naked fire, under constant stirring, until gas bubbles rise, or until the red color of the mixture begins to turn brown. Then moderate the heat, but keep up the stirring until the mixture has acquired a dark-brown color, and from time to time allow some drops of it to fall into cold water to test its consistence. When this is satisfactory, remove the vessel from the fire, add the Wax in small pieces, and finally the Camphor, previously rubbed to a smooth paste with a little Olive Oil. Mix thoroughly, allow the mixture to become somewhat cool, and while it is still warm, pour the plaster into paper moulds previously coated with mucilage containing about five per cent. of glycerin, and dried.

Note.—This preparation is official in the *German Pharmacopœia.*

120. EMPLASTRUM GALBANI. *N. F.*

(U. S. P., 1880.)

Galbanum Plaster.

Galbanum	16 Gm.
Turpentine	2 Gm.
Burgundy Pitch	6 Gm.
Lead Plaster	76 Gm.

To the Galbanum and Turpentine, previously melted together and strained, add, first, the Burgundy Pitch, then the Lead Plaster, melted over a gentle fire, and mix the whole thoroughly.

121. EMPLASTRUM PICIS CANADENSIS. *N. F.*

(U. S. P., 1880.)

Canada Pitch Plaster.

Canada Pitch	90 Gm.
Yellow Wax	10 Gm.

Melt them together, strain the mixture, and stir constantly until it thickens on cooling.

122. EMPLASTRUM PICIS LIQUIDÆ COMPOSITUM. *N. F.*

Compound Tar Plaster.

Resin	50 Gm.
Tar	40 Gm.
Podophyllum, in No. 60 powder	10 Gm.
Phytolacca Root, in No. 60 powder	10 Gm.
Sanguinaria, in No. 60 powder	10 Gm.

Melt the Resin and Tar together, then stir in the mixed powders, and, as the mass cools, mould it into rolls or pour it into boxes.

123. EMULSIONES. *N. F.*

Emulsions.

The successful formation of Emulsions, whether of fixed or volatile Oils, is most satisfactorily and expeditiously accomplished with Acacia as the emulsifying agent. Hence, preference is given Acacia in this Formulary, though other emulsifying agents are not ignored, and their use and application are exemplified in a number of alternative formulas for preparing Emulsion of Cod-Liver Oil.

A. *Emulsification.* When Acacia is used as the emulsifying agent, it is important that the Oil, the Acacia, and the Water shall primarily be in absolutely definite proportion *by weight.* This proportion is *eight* (8) *parts* of Oil, *two* (2) *parts* of Acacia, and *three* (3) *parts* of Water. The Oil (8) and Acacia (2), in fine powder, are weighed into a mortar, and well mixed by trituration; the Water (3) is then added *in one portion,* and the whole is triturated briskly until a thick, creamy emulsion is produced, the sides of the mortar being carefully scraped, and the mixture again triturated so as to insure the complete emulsification of all the Oil. During warm weather, the Water and Oil should be cooled. The other ingredients may then be gradually added; first the flavoring, then the greater part of Water necessary to make the final quantity, then the Syrup, etc. Finally the quantity is adjusted by the addition of sufficient Water.

Alcoholic liquids should be added last, and should be previously mixed with a portion of the Water.

If these simple conditions and directions are carefully observed, and particularly if the proportions by weight are accurate, a perfect Emulsion is obtained with certainty and rapidity.

With other emulsifying agents—Mucilage of Irish Moss, Mucilage of Dextrin, Glycerite of Egg, Tincture of Quillaja—the proportions need not be adjusted with the same minuteness. It suffices to place the emulsifier into a bottle or mortar, and to add the oil in small portions at a time, shaking or triturating briskly after each addition until emulsification is completed. Obviously, the preparation of this class of emulsions is very much facilitated by mechanical contrivances that are capable of producing brisk agitation and mingling of the two fluids, and such are necessarily resorted to when emulsions are to be made

in large quantities for the market. But none of them are as perfect as the emulsions made with Acacia.

B. *Flavoring.* Since no single or compound aromatic can be devised which would be acceptable under all circumstances as a flavoring for Emulsion of Cod-Liver Oil, the selection of the most suitable aromatic must be left to the prescriber or dispenser. Among those which are found to be most serviceable are the following, the quantities given below being intended for *one thousand* (1000) *cubic centimeters* of finished emulsion, though in some cases a smaller or larger quantity, in the same proportions, may be preferable:

1.	Oil of Gaultheria	4 Cc.
2.	Oil of Gaultheria	2 Cc.
	Oil of Sassafras	2 Cc.
3.	Compound Spirit of Orange (U.S.P.)	1.5 Cc.
4.	Oil of Gaultheria	2 Cc.
	Oil of Bitter Almond	0.25 Cc.
	Oil of Coriander	0.25 Cc.
5.	Oil of Gaultheria	1.5 Cc.
	Oil of Sassafras	1.5 Cc.
	Oil of Bitter Almond	0.25 Cc.
6.	Oil of Gaultheria	2.5 Cc.
	Oil of Bitter Almond	2.5 Cc.
7.	Oil of Neroli	1.5 Cc.
	Oil of Bitter Almond	1.5 Cc.
	Oil of Cloves	0.25 Cc.

C. *Preservation.* When an Emulsion of Cod-Liver Oil is to be kept for some time, its deterioration may be prevented or retarded by the addition of *sixty-five* (65) *cubic centimeters* of Alcohol in the place of the same quantity of Water, when making *one thousand* (1000) *cubic centimeters* of Emulsion.

124. EMULSIO OLEI MORRHUÆ. *N. F.*

Emulsion of Cod-Liver Oil.

Cod-Liver Oil	464 Gm.
Acacia, in fine powder	116 Gm.
Syrup of Tolu (U. S. P.)	100 Cc.
Flavoring (F. 123, B.),	
Water, of each, a sufficient quantity	
To make	1000 Cc.

Triturate the Oil and Acacia together in a mortar. Carefully weigh out *one hundred and seventy-four* (174) *grammes* of Water, and add it *at once* to the mixture of Oil and Acacia, triturating briskly until a thick creamy emulsion is produced. To this add the desired flavoring, the Syrup of Tolu, and enough Water to make *one thousand* (1000) *cubic centimeters* of finished emulsion.

Alternative Formulas. Emulsion of Cod-Liver Oil may also be prepared by any other method capable of emulsifying Oil, the following formulas being given as examples:

1. Irish Moss Emulsion of Cod-Liver Oil.

Cod-Liver Oil	500 Cc.
Mucilage of Irish Moss (F. 275)	325 Cc.
Syrup of Tolu (U. S. P.)	100 Cc.
Flavoring (F. 123, B.),	
Water, of each, a sufficient quantity	
To make	1000 Cc.

Pour the Mucilage of Irish Moss into a suitable bottle, add the Cod-Liver Oil in divided portions, shaking well after each addition, and, when a perfect Emulsion is formed, add the Syrup of Tolu, and Flavoring, and lastly, enough Water to make *one thousand* (1000) *cubic centimeters*. Finally, mix the whole thoroughly together.

2. Glyconin Emulsion of Cod-Liver Oil.

Cod-Liver Oil	500 Cc.
Glycerite of Yolk of Egg (U. S. P.)	175 Cc.
Syrup of Tolu (U. S. P.)	100 Cc.
Flavoring (F. 123, B.),	
Water, of each, a sufficient quantity	
To make	1000 Cc.

Triturate the Glycerite of Yolk of Egg (Glyconin) in a mortar with the Oil, added in small portions at a time, and thoroughly incorporate each portion before adding the next. Then, continuing the trituration, gradually add the Syrup of Tolu, and Flavoring. Finally, add enough Water to make *one thousand* (1000) *cubic centimeters*, and mix the whole thoroughly together.

3. Dextrin Emulsion of Cod-Liver Oil.

Cod-Liver Oil	500 Cc.
Mucilage of Dextrin (F. 277)	325 Cc.
Syrup of Tolu (U. S. P.)	125 Cc.
Flavoring (F. 123, B.),	
Water, of each, a sufficient quantity	
To make	1000 Cc.

To the Mucilage of Dextrin contained in a suitable bottle add the Cod-Liver Oil, first in small portions, agitating each time, until the last added portion is emulsified. Then add the Flavoring, the Syrup of Tolu, and lastly, enough Water to make *one thousand* (1000) *cubic centimeters*, and mix the whole thoroughly together.

4. Quillaja Emulsion of Cod-Liver Oil.

Cod-Liver Oil	500 Cc.
Tincture of Quillaja (U. S. P.)	65 Cc.
Syrup of Tolu (U. S. P.)	100 Cc.
Flavoring (F. 123, B.),	
Water, of each, a sufficient quantity	
To make	1000 Cc.

Pour the Tincture into a suitable bottle, then add the Cod-Liver Oil in portions of about *one hundred and twenty-five* (125) *cubic centimeters* each, and shake after each addition until a perfect emulsion results. Next add the Syrup of Tolu, and the Flavoring, and lastly, enough Water to make *one thousand* (1000) *cubic centimeters*. Finally, mix the whole thoroughly together.

An 85-per-cent. Emulsion of Cod-Liver Oil may be prepared by mixing in the manner just prescribed:

Cod-Liver Oil	850 Cc.
Tincture of Quillaja (U. S. P.)	100 Cc.
Flavoring (F. 123, B.),	
Syrup of Tolu (U. S. P.), of each, a sufficient quantity	
To make	1000 Cc.

Note.—Emulsion of Cod-Liver Oil made with Quillaja should not be dispensed without the direction or consent of the prescriber.

125. EMULSIO OLEI MORRHUÆ CUM CALCII ET SODII PHOSPHATIBUS. *N. F.*

Emulsion of Cod-Liver Oil with Calcium and Sodium Phosphates.

Emulsion of Cod-Liver Oil with Phosphates of Lime and Soda.

Cod-Liver Oil	464 Gm.
Acacia, in fine powder	116 Gm.
Calcium Phosphate	17.5 Gm.
Sodium Phosphate	17.5 Gm.
Syrup of Tolu (U. S. P.)	100 Cc.
Flavoring (F. 123, B.),	
Water, of each, a sufficient quantity	
To make	1000 Cc.

Emulsify the Oil with the Acacia and *one hundred and seventy-four* (174) *grammes* of Water, as directed under Emulsio Olei Morrhuæ (F. 124), and add the Flavoring. Then triturate the Salts to a fine powder, incorporate with the Syrup and a portion of the remaining Water, and triturate with the emulsified Oil. Finally, add enough Water to make *one thousand* (1000) *cubic centimeters*, and mix the whole thoroughly together.

126. EMULSIO OLEI MORRHUÆ CUM CALCII LACTOPHOSPHATE. *N.F.*

Emulsion of Cod-Liver Oil with Calcium Lactophosphate.

Emulsion of Cod-Liver Oil with Lactophosphate of Lime.

Cod-Liver Oil	464 Gm.
Acacia, in fine powder	116 Gm.
Calcium Lactate	35 Gm.
Phosphoric Acid (U. S. P., 85 %)	20 Gm.
Syrup of Tolu (U. S. P.)	100 Gm.
Flavoring (F. 123, B.),	
Water, of each, a sufficient quantity	
To make	1000 Cc.

Emulsify the Oil with the Acacia and *one hundred and seventy-four* (174) *grammes* of Water, as directed under Emulsio Olei Morrhuæ (F. 124), and add the Flavoring. Then dissolve the Calcium Lactate in *sixty-five* (65) *cubic centimeters* of Water with the aid of the Phosphoric Acid, add the solution gradually to the Emulsified Oil, then the Syrup, and lastly, enough Water to make *one thousand* (1000) *cubic centimeters*. Mix the whole thoroughly.

This Emulsion should be freshly prepared when dispensed.

127. EMULSIO OLEI MORRHUÆ CUM CALCII PHOSPHATE. *N. F.*

Emulsion of Cod-Liver Oil with Calcium Phosphate.

Emulsion of Cod-Liver Oil with Phosphate of Lime.

Cod-Liver Oil	464 Gm.
Acacia, in fine powder	116 Gm.
Calcium Phosphate	35 Gm.
Syrup of Tolu (U. S. P.)	100 Cc.
Flavoring (F. 123, B.),	
Water, of each, a sufficient quantity	
To make	1000 Cc.

Emulsify the Oil with the Acacia and *one hundred and seventy-four* (174) *grammes* of Water, as directed under Emulsio Olei Morrhuæ (F. 124), and add the Flavoring. Then triturate the Calcium Phosphate with the Syrup and a portion of the remaining Water, add the mixture gradually to the emulsified Oil, and lastly, enough Water to make *one thousand* (1000) *cubic centimeters*. Mix the whole thoroughly.

128. EMULSIO OLEI MORRHUÆ CUM EXTRACTO MALTI. *N. F.*

Emulsion of Cod-Liver Oil with Extract of Malt.

Cod-Liver Oil	500 Cc.
Mucilage of Dextrin (F. 277)	125 Cc.
Extract of Malt	375 Cc.

To the Mucilage of Dextrin, contained in a suitable bottle, add the Extract of Malt, and mix them thoroughly by agitation. Then gradually add the Cod-Liver Oil, first in small portions, agitating each time until the last-added portion is perfectly incorporated.

Note.—Extract of Malt, most suitable for this preparation, should have about the same consistence as Balsam of Peru, at a temperature of 15° C. (59° F.).

129. EMULSIO OLEI MORRHUÆ CUM HYPOPHOSPHITE. *N. F.*

Emulsion of Cod-Liver Oil with Hypophosphite.

Cod-Liver Oil	464 Gm.
Acacia, in fine powder	116 Gm.
Any Soluble Hypophosphite	17.5 Gm.
Syrup of Tolu (U. S. P.)	100 Cc.
Flavoring (F. 123, B.),	
Water, of each, a sufficient quantity	
To make	1000 Cc.

Emulsify the Oil with the Acacia and *one hundred and seventy-four* (174) *grammes* of Water, as directed under Emulsio Olei Morrhuæ (F. 124), and add the Flavoring. Then dissolve the Hypophosphite in sufficient Water, mix this solution with the Syrup, and add the mixture gradually to the emulsified Oil. Lastly, add enough Water to make *one thousand* (1000) *cubic centimeters*, and mix the whole thoroughly.

Note.—If several Hypophosphites are required, equal parts of them may be used, amounting altogether to *seventeen and one-half* (17.5) *grammes* for the above formula. Varying quantities, larger or smaller than the above, may, of course, be used upon prescription.

130. EMULSIO OLEI MORRHUÆ CUM PRUNO VIRGINIANA. *N. F.*

Emulsion of Cod-Liver Oil with Wild Cherry.

Cod-Liver Oil	464 Gm.
Acacia, in fine powder	116 Gm.
Fluid Extract of Wild Cherry (U. S. P.)	65 Cc.
Syrup of Tolu (U. S. P.)	100 Cc.
Flavoring (F. 123, B.),	
Water, of each, a sufficient quantity	
To make	1000 Cc.

Emulsify the Oil with the Acacia and *one hundred and seventy-four* (174) *grammes* of Water, as directed under Emulsio Olei Morrhuæ (F. 124), and add the Flavoring. Mix the Fluid Extract and the Syrup with a portion of the remaining Water, and add the mixture gradually to the emulsified Oil. Lastly, add enough Water to make *one thousand* (1000) *cubic centimeters*, and mix the whole thoroughly.

131. EMULSIO OLEI RICINI. *N. F.*

Emulsion of Castor Oil.

Castor Oil	32 Gm.
Acacia, in fine powder	8 Gm.
Tincture of Vanilla (U. S. P.)	2.5 Cc.
Syrup (U. S. P.)	20 Cc.
Water, a sufficient quantity	
To make	100 Cc.

Carefully weigh the Castor Oil and the Acacia into a mortar, triturate until well mixed; carefully weigh out *twelve* (12) *grammes* of Water, and add *at once* to the mixture of Oil and Acacia, triturating briskly until a thick, creamy emulsion is produced. To this add gradually, with stirring, a mixture of the Syrup and Tincture with a portion of the remaining Water, and finally enough Water to make *one hundred* (100) *cubic centimeters*.

The Emulsion contains about *one-third* (⅓) of its volume of Castor Oil. The flavoring may be varied to suit prescription. It should be freshly prepared as required.

132. EMULSIO OLEI TEREBINTHINÆ. *N. F.*

Emulsion of Oil of Turpentine.

Oil of Turpentine	12.5 Cc.
Acacia, in fine powder	2 Gm.
Yolk of Egg	15 Cc.
Aromatic Elixir (U. S. P.)	15 Cc.
Cinnamon Water (U. S. P.), a sufficient quantity	
To make	100 Cc.

Triturate the Acacia with the Yolk of Egg, then add the Oil of Turpentine very slowly, continuing the trituration, and finally add the Aromatic Elixir, and enough Cinnamon Water to make *one hundred* (100) *cubic centimeters*.

Emulsion of Oil of Turpentine, or of any *Volatile Oil*, may also be prepared according to the following general formula:

Volatile Oil	12.5	Cc.
Acacia, in fine powder	6	Gm.
Syrup	25	Cc.
Water, a sufficient quantity		
To make	100	Cc.

Pour the Volatile Oil into a dry bottle, and, having corked the latter, agitate it so that the inner surface may be completely wetted by the Oil. Then add the Acacia and shake again. Finally, add the Syrup, and enough Water to make *one hundred* (100) *cubic centimeters*, and mix thoroughly.

Note.—If this general formula is applied to Emulsion of Oil of Turpentine, and a product similar to that obtained by the first formula is desired, the Syrup should be replaced by Aromatic Elixir and the Water by Cinnamon Water.

If a so-called "Emulsion" of a Volatile Oil is to be made more permanent, this may be accomplished by incorporating with it a small portion of some bland fixed Oil, such as Expressed Oil of Almond. Usually, 1 volume of the Fixed Oil will be sufficient for 2 volumes of the Volatile Oil.

In this case, the mixture should be made in a mortar, by trituration, and under observation of the rule laid down in general formula for Emulsions (F. 123).

133. EMULSIO OLEI TEREBINTHINÆ FORTIOR. *N. F.*

Stronger Emulsion of Oil of Turpentine.

Forbes's Emulsion of Oil of Turpentine.

Oil of Turpentine	50	Cc.
Acacia, in fine powder	2.5	Gm.
Water	50	Cc.

Pour the Oil of Turpentine into a perfectly dry vial, having a capacity of a little more than *one hundred* (100) *cubic centimeters*, and shake so that the inner surface may be completely wetted by the Oil. Then add the Acacia, and shake again. Now add one-half of the Water, and shake until the Oil separates in form of a milky Emulsion. Add the remainder of the Water, and continue the shaking until the Oil separates from the Water in the form of a creamy Emulsion upon standing.

This Emulsion must be shaken before dispensing.

Note.—The formula for this strong Emulsion of Oil of Turpentine is essentially that proposed by Mr. J. Winchell Forbes, in 1872. While the Oil separates in the form of a cream-like layer upon standing, the two liquids are easily united by brief shaking. It keeps well, and is useful for dispensing small quantities of Oil of Turpentine in a fairly well emulsified condition.

134. EMULSIO PHOSPHATICA. *N. F.*

Phosphatic Emulsion.

Mistura Phosphatica.

Cod-Liver Oil	250	Cc.
Glycerite of Yolk of Egg (U. S. P.)	165	Gm.
Diluted Phosphoric Acid (U. S. P.)	50	Cc.
Oil of Bitter Almond	1.5	Cc.
Rum (Jamaica)	250	Cc.
Orange Flower Water (U. S. P.), a sufficient quantity		
To make	1000	Cc.

To the Glycerite of Yolk of Egg (Glyconin) contained in a suitable bottle, gradually add the Cod-Liver Oil, in small portions at a time, shaking after each addition, until the added portion is emulsified. Then gradually add the Phosphoric Acid, Rum, and Oil of Bitter Almond, incorporating them thoroughly. Finally, add enough Orange Flower Water to make *one thousand* (1000) *cubic centimeters*, and mix the whole thoroughly.

135. EXTRACTA FLUIDA. *N. F.*

Fluid Extracts.

The Fluid Extracts for which formulas are given in this Formulary are intended to be of the same strength as the Fluid Extracts of the United States Pharmacopœia, which directs that *one hundred* (100) *cubic centimeters* of Fluid Extract shall be obtained from *one hundred* (100) *grammes* of the drug.

General Processes. The Fluid Extracts of this Formulary are to be prepared according to one of the following two processes, the particular one to be employed being designated in each case. These two processes are necessary because, in the preparation of some Fluid Extracts, two fluids are successively used, the first containing Glycerin, and being in definite proportion to the drug used, while the second is free from Glycerin, being intended for the exhaustion of the drug and subsequent evaporation. Accordingly these menstrua are designated as *Menstruum I.* (containing Glycerin) and *Menstruum II.* (containing no Glycerin). As an alternative to either of these processes, a third process, dependent upon *Fractional Percolation*, may be used. In this the use of heat is avoided, and it involves the use of only one kind of menstruum, even in the case of drugs, for which two different menstrua (I. and II.) are prescribed in this Formulary. In the case of the latter, a sufficient quantity of Menstruum I. must be prepared to serve throughout the process.

Process A. The Menstruum contains no Glycerin.

Moisten *one thousand* (1000) *grammes* of the drug with a sufficient quantity of the prescribed menstruum to render it distinctly damp and to maintain it so after several hours' maceration in a well-covered vessel. When the drug has ceased to swell, pack it in a suitable percolator, pour a sufficient quantity of the menstruum on top, and, when the percolate begins to drop from the orifice, close the latter, cover the percolator, and allow the contents to macerate twenty-four hours. Then permit the percolation to proceed. Receive the first *eight hundred and seventy-five* (875) *cubic centimeters* of the percolate separately and set it aside. Then continue the percolation with the same menstruum until the drug is practically exhausted. Evaporate this second portion—at a temperature sufficiently low to prevent the loss of any important volatile constituent—to a soft extract, and dissolve this in a sufficient quantity of menstruum so that when this is added to the reserved portion, the product will measure *one thousand* (1000) *cubic centimeters*. Allow the Fluid Extract to stand a few days, or longer, if convenient, and filter, if necessary.

Process B. The Menstruum contains Glycerin.

Moisten *one thousand* (1000) *grammes* of the drug with a sufficient quantity of Menstruum I. to render it distinctly damp and to maintain it so after several hours' maceration in a well-covered vessel. When the drug has ceased to swell, pack it in a suitable percolator and pour the remainder of Menstruum I. on top. When this has just disappeared from the surface, follow it by a sufficient quantity of Menstruum II. As soon as the percolate begins to drop from the orifice, close the latter, cover the percolator, and allow the contents to macerate during twenty-four hours. Then permit the percolation to proceed. Receive the first *eight hundred and seventy-five* (875) *cubic centimeters* of the percolate separately and set it aside. Then continue the percolation with Menstruum II., until the drug is practically exhausted. Evaporate this second portion—at a temperature sufficiently low to prevent the loss of any important volatile constituent—to a soft extract, and dissolve this in a sufficient quantity of Menstruum II., so that when this is added to the reserved portion, the product will measure *one thousand* (1000) *cubic centimeters*. Allow the Fluid Extract to stand a few days, or longer, if convenient, and filter, if necessary.

Process C. Fractional Percolation.

Take of the drug, in powder of the prescribed fineness, *one thousand* (1000) *grammes*, and divide it into three portions, of *five hundred* (500), *three hundred and twenty-five* (325), and *one hundred and seventy-five* (175) *grammes*, respectively.

Moisten the first portion of the drug (500 Gm.) with the menstruum and percolate in the usual manner. Set aside the first *one hundred and seventy-five* (175) *cubic centimeters* of percolate, and continue until *fifteen hun-*

dred (1500) *cubic centimeters* more of percolate have passed, which must be received in several portions, so that the more concentrated will be separate from the last, weak percolate.

Then moisten the second portion of the drug (325 Gm.) with the more concentrated percolates received during the preceding operation after the first *one hundred and seventy-five* (175) *cubic centimeters* have passed, and percolate again in the usual manner, using the several reserved percolates, successively, as menstrua. Set aside the first *three hundred and twenty-five* (325) *cubic centimeters*, and continue the percolation until *six hundred and fifty* (650) *cubic centimeters* more have passed, which should also be received in several portions.

Finally moisten the third portion of the drug (175 Gm.) with the most concentrated of the last reserved percolates, and proceed as directed for the second portion. Collect *five hundred* (500) *cubic centimeters* of percolate, and mix with the two portions (325 and 175 Cc.) previously set aside, so as to make *one thousand* (1000) *cubic centimeters* of Fluid Extract.

Note.—If this method is applied to drugs for which the Process B. is directed, use a sufficient quantity of Menstruum I. to obtain the required quantities of percolate, and omit the use of Menstruum II.

136. EXTRACTUM ADONIDIS FLUIDUM. *N. F.*

Fluid Extract of Adonis.

From the root of *Adonis vernalis* Linné (Bird's Eye).
Process A (see F. 135).—No. 60 powder.
Menstruum: Alcohol.

137. EXTRACTUM ALETRIDIS FLUIDUM. *N. F.*

Fluid Extract of Aletris.

From the rhizome of *Aletris farinosa* Linné (Star-grass).
Process A (see F. 135).—No. 60 powder.
Menstruum: Diluted Alcohol.

138. EXTRACTUM ANGELICÆ RADICIS FLUIDUM. *N. F.*

Fluid Extract of Angelica Root.

From the root of *Angelica Archangelica* Linné (Angelica).
Process A (see F. 135).—No. 60 powder.
Menstruum: Alcohol, 3 volumes.
Water, 2 volumes.

139. EXTRACTUM APII GRAVEOLENTIS FLUIDUM. *N. F.*

Fluid Extract of Celery.

From the seed of *Apium graveolens* Linné (Celery).
Process A (see F. 135).—No. 60 powder.
Menstruum: Alcohol, 2 volumes.
Water, 1 volume.

140. EXTRACTUM ARALIÆ RACEMOSÆ FLUIDUM. *N F.*

Fluid Extract of Aralia Racemosa.

From the root of *Aralia racemosa* Linné (American Spikenard).
Process A (see F. 135).—No. 60 powder.
Menstruum: Alcohol, 2 volumes.
Water, 1 volume.

141. EXTRACTUM ARNICÆ FLORUM FLUIDUM. *N. F.*

Fluid Extract of Arnica Flowers.

From the flower heads of *Arnica montana* Linné (Arnica).
Process A (see F. 135).—No. 40 powder.
Menstruum: Diluted Alcohol.

142. EXTRACTUM BERBERIDIS VULGARIS FLUIDUM. *N. F.*

Fluid Extract of Berberis Vulgaris.

From the bark of the root of *Berberis vulgaris* Linné (Barberry).
Process A (see F. 135).—No. 60 powder.
Menstruum: Alcohol, 3 volumes.
Water, 2 volumes.

143. EXTRACTUM BOLDI FLUIDUM. *N. F.*

Fluid Extract of Boldo.

From the leaves of *Peumus Boldus* Molina (Boldo).
Process A (see F. 135).—No. 60 powder.
Menstruum: Alcohol, 2 volumes.
Water, 1 volume.

144. EXTRACTUM BUCHU FLUIDUM COMPOSITUM. *N. F.*

Compound Fluid Extract of Buchu.

Buchu	**625 Gm.**
Cubeb	**125 Gm.**
Juniper	**125 Gm.**
Uva Ursi	**125 Gm.**

Process A (see F. 135).—No. 40 powder.
Menstruum: Alcohol, 2 volumes.
Water, 1 volume.

145. EXTRACTUM CALENDULÆ FLUIDUM. *N. F.*

Fluid Extract of Calendula.

From the flowering herb of *Calendula officinalis* Linné (Marigold).
Process A (see F. 135).—No. 40 powder.
Menstruum: Alcohol, 2 volumes.
Water, 1 volume.

146. EXTRACTUM CAMELLIÆ FLUIDUM. *N. F.*

Fluid Extract of Camellia.

From the commercial dried leaves of *Camellia Thea* Link (Tea).
Process B (see F. 135).—No. 40 powder.
Menstruum I.: Alcohol, *two hundred and fifty* (250) *cubic centimeters.*
Water, *six hundred and eighty-five* (685) *cubic centimeters.*
Glycerin, *sixty-five* (65) *cubic centimeters.*
Menstruum II.: Alcohol, 1 volume.
Water, 3 volumes.

Note.—It is recommended that the best quality of commercial black tea, preferably "Formosa Oolong," be employed for this preparation.

147. EXTRACTUM CAULOPHYLLI FLUIDUM. *N. F.*

Fluid Extract of Caulophyllum.

From the rhizome and rootlets of *Caulophyllum thalictroides* Michaux (Blue Cohosh).
Process A (see F. 135).—No. 60 powder.
Menstruum: Alcohol, 3 volumes.
Water, 1 volume.

148. EXTRACTUM COFFEÆ VIRIDIS FLUIDUM. *N. F.*

Fluid Extract of Green Coffee.

From the commercial, unroasted seeds of *Coffea arabica* Linné (Coffee).
Process B (see F.). 135—No. 20 powder.

Menstruum I.: Alcohol, *two hundred and fifty* (250) *cubic centimeters.*
Water, *six hundred and eighty-five* (685) *cubic centimeters.*
Glycerin, *sixty-five* (65) *cubic centimeters.*
Menstruum II.: Alcohol, 1 volume.
Water, 3 volumes.

Note.—It is recommended that the best quality of either of the commercial varieties known as "Java" or "Mocha" Coffee be employed for this preparation.

149. EXTRACTUM COFFEÆ TOSTÆ FLUIDUM. *N. F.*

Fluid Extract of Roasted Coffee.

From the commercial roasted seeds of *Coffea arabica* Linné (Coffee).

Process B (see F. 135).—No. 20 powder.
Menstruum I.: Alcohol, *two hundred and fifty* (250) *cubic centimeters.*
Water, *six hundred and eighty-five* (685) *cubic centimeters.*
Glycerin, *sixty-five* (65) *cubic centimeters.*
Menstruum II.: Alcohol, 1 volume.
Water, 3 volumes.

Note.—See the note to the preceding.

150. EXTRACTUM CONVALLARIÆ FLORUM FLUIDUM. *N. F.*

Fluid Extract of Convallaria Flowers.

From the flowers of *Convallaria majalis* Linné (Lily of the Valley).

Process A (see F. 135).—No. 40 powder.
Menstruum: Diluted Alcohol.

151. EXTRACTUM COPTIS FLUIDUM. *N. F.*

Fluid Extract of Coptis.

From the rhizome and rootlets of *Coptis trifolia* Salisbury (Goldthread).

Process A (see F. 135.—No. 40 powder.
Menstruum: Diluted Alcohol.

152. EXTRACTUM CORNUS FLUIDUM. *N. F.*

(U. S. P., 1880.)

Fluid Extract of Cornus.

From the bark of the root of *Cornus Florida* Linné (Dogwood).

Process B (see F. 135).—No. 60 powder.
Menstruum I.: Glycerin, *one hundred and fifty* (150) *cubic centimeters.*
Diluted Alcohol, *eight hundred and fifty* (850) *cubic centimeters.*
Menstruum II.: Diluted Alcohol.

153. EXTRACTUM CORNUS CIRCINATÆ FLUIDUM. *N. F.*

Fluid Extract of Cornus Circinata.

From the bark of *Cornus circinata* L'Héritier (Green Osier).

Process A (see F. 135.—No. 40 powder.
Menstruum: Diluted Alcohol.

154. EXTRACTUM CORYDALIS FLUIDUM. *N. F.*

Fluid Extract of Corydalis.

From the tubers of *Dicentra canadensis* De Candolle (Turkey Corn).

Process A (see F. 135).—No. 60 powder.
Menstruum: Alcohol, 3 volumes.
Water, 1 volume.

155. EXTRACTUM COTO FLUIDUM. *N. F.*

Fluid Extract of Coto.

From Coto bark, derived from an undetermined tree, native of tropical South America.

Process A (see F. 135).—No. 60 powder.
Menstruum: Alcohol, 9 volumes.
Water, 1 volume.

156. EXTRACTUM FERRI POMATUM. *N. F.*

Ferrated Extract of Apples.

Ferri Malas Crudus. Crude Malate of Iron.

Iron, in the form of fine, bright wire, and cut . . . . . **20 Gm.**
Ripe Sour Apples . . . . . **1000 Gm.**
Water . . . . . **a sufficient quantity.**

Convert the Sour Apples into a homogeneous pulp by pounding or grinding, and express the liquid portion. Then mix the latter with the Iron in an enamelled or porcelain vessel, macerate for forty-eight hours, and then apply the heat of a water-bath, until no more bubbles of gas are given off, adding a little water from time to time to make up any loss by evaporation. Dilute the liquid with Water to make it weigh *one thousand* (1000) *grammes*, and set it aside for a few days. Then filter, and evaporate the filtrate in the before-mentioned vessel to a thick extract, which should be greenish-black, and should yield a clear solution with water.

157. EXTRACTUM FUCI FLUIDUM. *N. F.*

Fluid Extract of Fucus.

From the thallus of *Fucus vesiculosus* Linné (Bladder-wrack).

Process A (see F. 135).—No. 40 powder.
Menstruum: Alcohol, 3 volumes.
Water, 1 volume.

158. EXTRACTUM GLYCYRRHIZÆ DEPURATUM. *N. F.*

Purified Extract of Glycyrrhiza.

Purified Extract of Liquorice.

Extract of Glycyrrhiza, in sticks,
Water, each . . . . . **a sufficient quantity.**

Put a layer of well-washed rye-straw over the bottom of a keg or other suitable tall vessel. Then put a single layer of sticks of Extract of Glycyrrhiza, broken into coarse pieces, over it. Continue to put in alternate layers of straw and Extract of Glycyrrhiza until the vessel is full or the whole of the Extract has been disposed of. Fill the vessel with cold Water, and allow it to remain for three days. Then draw off the solution which has formed, by means of a faucet, or siphon, or otherwise, refill the vessel with cold Water, and proceed as before. Mix the several solutions obtained, allow any suspended matter to subside, decant the clear solution, and strain the remainder without pressure. Finally, evaporate the liquid on a water-bath to the consistence of a pilular extract.

Note.—Purified Extract of Glycyrrhiza should not be confounded with the official Pure Extract of Glycyrrhiza (*Extractum Glycyrrhizæ Purum*).

159. EXTRACTUM HELIANTHEMI FLUIDUM. *N. F.*

Fluid Extract of Helianthemum.

From the herb of *Helianthemum canadense* Michaux (Frost-wort).

Process A (see F. 135).—No. 40 powder.
Menstruum: Diluted Alcohol.

160. EXTRACTUM HUMULI FLUIDUM. *N. F.*

Fluid Extract of Hops.

From the strobiles of *Humulus Lupulus* Linné (Hops).

Process A (see F. 135).—No. 20 powder.
Menstruum: Alcohol, 5 volumes.
Water, 3 volumes.

161. EXTRACTUM HYDRANGEÆ FLUIDUM. *N. F.*

Fluid Extract of Hydrangea.

From the root of *Hydrangea arborescens* Linné (Seven Barks).
Process A (see F. 135).—No. 60 powder.
Menstruum: Alcohol, 3 volumes.
Water, 2 volumes.

162. EXTRACTUM JALAPÆ FLUIDUM. *N. F.*

Fluid Extract of Jalap.

From the tuberous root of *Exogonium Purga* Bentham (Jalap).
Process A (see F. 135).—No. 60 powder.
Menstruum: Alcohol.

163. EXTRACTUM JUGLANDIS FLUIDUM. *N. F.*

Fluid Extract of Juglans.

From the inner bark of the root of *Juglans cinerea* Linné (Butternut).
Process A (see F. 135).—No. 40 powder.
Menstruum: Diluted Alcohol.

164. EXTRACTUM JUNIPERI FLUIDUM. *N. F.*

Fluid Extract of Juniper.

From the fruit of *Juniperus communis* Linné (Juniper).
Process A (see F. 135).—No. 10 powder.
Menstruum: Diluted Alcohol.

165. EXTRACTUM KAVÆ FLUIDUM. *N.F.*

Fluid Extract of Kava.

From the root of *Piper methysticum* Forster (Kava; Kava-kava; Ava).
Process A (see F. 135).—No. 40 powder.
Menstruum: Alcohol, 3 volumes.
Water, 2 volumes.

166. EXTRACTUM LACTUCARII FLUIDUM. *N. F.*

(U. S. P., 1880.)

Fluid Extract of Lactucarium.

Lactucarium, in coarse pieces . . . . . **100 Gm.**
Ether . . . . . **125 Cc.**
Alcohol,
Water, each . . . . . **a sufficient quantity.**

Add the Lactucarium to the Ether contained in a tared flask having the capacity of *six hundred* (600) *cubic centimeters*, and let it macerate for twenty-four hours; then add *three hundred* (300) *cubic centimeters* of Water, and shake the mixture well. Fit a bent glass tube into the neck of the flask, and, having immersed the flask in hot water, recover the Ether by distillation. When all the Ether has distilled over, remove the tube, and, after thoroughly shaking the contents of the flask, continue the heat for half an hour. Let the mixture cool, add *one hundred* (100) *grammes* of Alcohol, and enough Water to make the whole mixture weigh *five hundred* (500) *grammes;* after maceration for twenty-four hours, with occasional agitation, express and filter the liquid. Return the dregs to the flask and macerate them with *two hundred* (200) *grammes* of a mixture of Alcohol and Water made in the proportion of *one* (1) *part* of Alcohol to *three* (3) *parts* of Water; repeat the maceration two or three times, successively, with fresh portions of the mixture, until the dregs are tasteless, or nearly so. Mix, and filter the liquids thus obtained, and concentrate them, by means of a water-bath (the first expressed liquid by itself), until the combined weight of the liquids is *sixty* (60) *grammes;* mix the liquids, add *forty* (40) *grammes* of Alcohol, and let the mixture cool in the evaporating vessel, stirring the mixture frequently, and during the intervals keeping the vessel well covered. When cool, add enough Alcohol to make the mixture weigh *one hundred* (100) *grammes*, transfer the liquid to a flask, and add enough Water to make the mixture measure *one hundred* (100) *cubic centimeters*, using the Water so required to rinse the evaporating vessel. Shake the mixture occasionally, during several hours (and frequently, if a portion of the precipitate is found to be tenacious), and, when a uniform mixture results, set it aside for twenty-four hours, so that any precipitate formed may subside. Decant the clear liquid, transfer the precipitate to a filter, and, after thoroughly draining it into the decanted liquid, wash it with a mixture of Alcohol and Water made in the proportion of *three* (3) *parts* of Alcohol to *four* (4) *parts* of Water, until the washings pass tasteless. Concentrate the washings, by evaporation, to a syrupy consistence, mix with the decanted liquid, and add enough to the last-named mixture of Alcohol and Water to make the whole measure *one hundred* (100) *cubic centimeters*. Lastly, after twenty-four hours, having meanwhile shaken the Fluid Extract occasionally, filter it through paper.

167. EXTRACTUM MALTI. *N. F.*

(U. S. P., 1880.)

Extract of Malt.

Malt, in coarse powder, not finer than No. 12 . . . . . **1000 Gm.**
Water . . . . . **a sufficient quantity.**

Upon the powder, contained in a suitable vessel, pour *one thousand* (1000) *cubic centimeters* of Water, and macerate for six hours. Then add *four thousand* (4000) *cubic centimeters* of Water, heated to about 30° C. (86° F.), and digest for an hour at a temperature not exceeding 55° C. (131° F.). Strain the mixture with strong expression. Finally, by means of a water-bath or vacuum-apparatus, at a temperature not exceeding 55° C. (131° F.), evaporate the strained liquid rapidly to the consistence of thick honey.

Keep the product in well-closed vessels, in a cool place.

168. EXTRACTUM MALTI FLUIDUM. *N. F.*

Fluid Extract of Malt.

Malt . . . . . **1000 Gm.**
Alcohol,
Water, each . . . . . **a sufficient quantity.**

Reduce the Malt to a coarse powder, not finer than No. 20. Moisten it with *five hundred* (500) *cubic centimeters* of a mixture of *one* (1) *volume* of Alcohol and *three* (3) *volumes* of Water, and set it aside, well covered, until it has ceased to swell. Then mix it with as much of the menstruum as it will take up without dripping, pack it uniformly, but without pressure, in a percolator, and add enough of the before-mentioned menstruum to cover it. When the liquid begins to drop from the orifice, close the latter, and allow the contents to macerate during twenty-four hours, adding from time to time more menstruum, if necessary, to keep the malt just covered. Then remove the cork and allow the percolation to proceed until the percolate weighs *seven hundred and fifty* (750) *grammes*. Set this aside, well corked, until any suspended matters have been deposited. Then decant the clear liquid and preserve it for use.

Note.—The product thus obtained may be regarded as being practically equivalent to the drug in the proportion of minim for grain, the apparent excess of dissolved matters present in the first portions of the percolate being about offset by the soluble matters still remaining in the drug when the percolation is interrupted.

169. EXTRACTUM MENYANTHIS FLUIDUM. *N. F.*

Fluid Extract of Menyanthes.

From the leaves of *Menyanthes trifoliata* Linné (Buckbean. — Trifolium fibrinum *Germ. Pharm.*).

Process A (see F. 135).—No. 20 powder.
Menstruum: Diluted Alcohol.

170. EXTRACTUM MEZEREI FLUIDUM. *N. F.*

(U. S. P., 1880.)

Fluid Extract of Mezereum.

From the bark of *Daphne Mezereum* Linné, and of other species of *Daphne* (*Mezereum*).
Process A (see F. 135).—No. 30 powder.
Menstruum: Alcohol.

171. EXTRACTUM PETROSELINI RADICIS FLUIDUM. *N. F.*

Fluid Extract of Parsley Root.

From the root of *Petroselinum sativum* Hoffmann (Parsley).
Process A (see F. 135).—No. 40 powder.
Menstruum: Diluted Alcohol.

172. EXTRACTUM QUILLAJÆ FLUIDUM. *N. F.*

Fluid Extract of Quillaja.

From the bark of *Quillaja Saponaria* Molina (Soap-Bark).
Process A (see F. 135).—No. 40 powder.
Menstruum: Diluted Alcohol.

173. EXTRACTUM RHAMNI PURSHIANÆ FLUIDUM AROMATICUM.

Aromatic Fluid Extract of Rhamnus Purshiana.

Aromatic Fluid Extract of Cascara Sagrada.

Rhamnus Purshiana, in No. 60 powder	**1000 Gm.**
Glycyrrhiza, in No. 40 powder	**100 Gm.**
Calcined Magnesia	**125 Gm.**
Glycerin	**250 Cc.**
Compound Spirit of Orange (U. S. P.)	**10 Cc.**
Alcohol	**500 Cc.**
Water,	
Diluted Alcohol (U. S. P.), of each, a sufficient quantity	
To make	**1000 Cc.**

Mix the powdered drugs and the Magnesia with *two thousand* (2000) *cubic centimeters* of Water; macerate for twelve hours and then dry the mixture on a water-bath at a gentle heat. Mix the Glycerin and the Alcohol with *two hundred and fifty* (250) *cubic centimeters* of Water, and percolate the dried powders with this menstruum, followed by Diluted Alcohol, according to the directions given under Process B (see F. 135). Reserve the first *eight hundred and fifty* (850) *cubic centimeters* that pass, and set this aside. Continue the percolation with Diluted Alcohol to practical exhaustion, evaporate this second portion to a soft extract, dissolve it in the reserved portion, and add the Compound Spirit of Orange and sufficient Diluted Alcohol to make *one thousand* (1000) *cubic centimeters* of Fluid Extract.

174. EXTRACTUM SENNÆ FLUIDUM DEODORATUM. *N. F.*

Deodorized Fluid Extract of Senna.

Senna, in No. 60 powder	**1000 Gm.**
Alcohol,	
Water, each, ...	**a sufficient quantity.**

Moisten the Senna with *three hundred and fifty* (350) *cubic centimeters* of Alcohol, pack it firmly in a percolator, and percolate it with Alcohol until it is practically exhausted by this menstruum. The alcoholic percolate thus obtained is to be rejected, and the alcohol may be recovered therefrom by distillation. Then take out the moist powder, dry it, and prepare a Fluid Extract by the Process and Menstruum below-mentioned:
Process A (see F. 135).
Menstruum: Diluted Alcohol.

175. EXTRACTUM STERCULIÆ FLUIDUM. *N. F.*

Fluid Extract of Sterculia.

From the seeds of *Sterculia acuminata* R. Brown (Cola: Kola).
Process B (see F. 135).—No. 20 powder.
Menstruum I.: Alcohol, *two hundred and fifty* (250) *cubic centimeters.*
Water, *six hundred and eighty-five* (685) *cubic centimeters.*
Glycerin, *sixty-five* (65) *cubic centimeters.*
Menstruum II.: Alcohol, 1 volume.
Water, 3 volumes.

176. EXTRACTUM STILLINGIÆ FLUIDUM COMPOSITUM. *N. F.*

Compound Fluid Extract of Stillingia.

Stillingia	**250 Gm.**
Corydalis (root)	**250 Gm.**
Iris	**125 Gm.**
Sambucus	**125 Gm.**
Chimaphila	**125 Gm.**
Coriander	**65 Gm.**
Xanthoxylum Berries	**60 Gm.**

Reduce the drugs to a moderately coarse (No. 40) powder, and prepare a Fluid Extract in the usual manner, by the Process and Menstrua below mentioned.
Process B (see F. 135).
Menstruum I.: Alcohol, *five hundred* (500) *cubic centimeters.*
Glycerin, *two hundred and fifty* (250) *cubic centimeters.*
Water, *two hundred and fifty* (250) *cubic centimeters.*
Menstruum II.: Diluted Alcohol.

177. EXTRACTUM TRILLII FLUIDUM. *N. F.*

Fluid Extract of Trillium.

From the rhizome of *Trillium erectum* Linné, and other species of *Trillium* (Bethroot).
Process A (see F. 135).—No. 40 powder.
Menstruum: Alcohol, 3 volumes.
Water, 2 volumes.

178. EXTRACTUM TURNERÆ FLUIDUM. *N. F.*

Fluid Extract of Turnera.

From the leaves of *Turnera microphylla* De Candolle, and other species of *Turnera* (Damiana).
Process A (see F. 135).—No. 20 powder.
Menstruum: Alcohol, 2 volumes.
Water, 1 volume.

179. EXTRACTUM URTICÆ FLUIDUM. *N. F.*

Fluid Extract of Urtica.

From the root of *Urtica dioica* Linné (Nettle).
Process A (see F. 135).—No. 40 powder.
Menstruum: Diluted Alcohol.

180. EXTRACTUM VERBASCI FLUIDUM. *N. F.*

Fluid Extract of Verbascum.

From the leaves and flowers of *Verbascum Thapsus* Linné (Mullein).
Process A (see F. 135).—No. 20 powder.
Menstruum: Diluted Alcohol.

181. EXTRACTUM VERBENÆ FLUIDUM. *N. F.*

Fluid Extract of Verbena.

From the root of *Verbena hastata* Linné (Vervain).

Process A (see F. 135).—No. 40 powder.

Menstruum: Diluted Alcohol.

182. EXTRACTUM ZEÆ FLUIDUM. *N. F.*

Fluid Extract of Zea.

Extractum Stigmatum Maydis Fluidum. Fluid Extract of Corn Silk.

From the stigmata of *Zea Mays* Linné (Indian Corn).

Process A (see F. 135).—No. 40 powder.

Menstruum: Diluted Alcohol.

183. FERRI HYPOPHOSPHIS. *N. F.*

Hypophosphite of Iron.

Ferric Hypophosphite.

Iron and Ammonium Sulphate (U. S. P.), in perfect crystals . . . . . **100 Gm.**
Sodium Hypophosphite . . . . . **67 Gm.**
Distilled Water . . . . . **a sufficient quantity.**

Dissolve the Iron and Ammonium Sulphate in *four hundred* (400) *cubic centimeters*, and the Sodium Hypophosphite in *one hundred and twenty-five* (125) *cubic centimeters*, of Distilled Water, and, if necessary, filter each solution. Then mix them, and stir thoroughly; after a short time transfer the mixture to a close linen or muslin strainer, and wash the precipitate with Distilled Water until the washings run off tasteless. Transfer the strainer to a warm place, and, when the contents are dry, preserve them for use.

Hypophosphite of Iron (*ferric*) may also be prepared in the following manner:

Calcium Hypophosphite . . . . . **100 Gm.**
Solution of Ferric Chloride (U. S. P.),
Distilled Water, of each . . **a sufficient quantity.**

Dissolve the Calcium Hypophosphite in *twelve hundred* (1200) *cubic centimeters* of Distilled Water, and filter the solution. To this add Solution of Ferric Chloride, in small portions, stirring well each time and allowing the precipitate to subside before adding a fresh portion. Towards the end, remove a small quantity of the clear supernatant liquid, add to it some Solution of Ferric Chloride diluted with ten times its volume of Water, and observe whether any turbidity occurs either at once or after a few minutes. If it remains clear, the precipitation may be regarded as complete. Then transfer the mixture to a close linen or muslin strainer, and wash the precipitate with Distilled Water, until the washings run off tasteless. Transfer the strainer to a warm place and, when the contents are dry, preserve them for use.

184. GELATINUM CHONDRI. *N. F.*

Irish Moss Gelatin.

Irish Moss . . . . . **1000 Gm.**
Water . . . . . **a sufficient quantity.**

Wash the Irish Moss with cold Water, then place it in a suitable vessel, add *fifty thousand* (50,000) *cubic centimeters* of hot Water, and heat it on a boiling water-bath, for fifteen minutes, frequently stirring. Strain the decoction, while hot, through a strong muslin strainer; return the strained, mucilaginous liquid to the water-bath, evaporate it to a semi-fluid consistence, then transfer it to shallow, flat-bottomed trays, and evaporate it at a temperature not exceeding 90° C. (194° F.), so that the Gelatin may become detached in scales.

Note.—Irish Moss Gelatin thus prepared furnishes a Mucilage of Irish Moss which is opaque, like that made directly from the Moss itself. It may be prepared so as to yield a transparent mucilage by following the plan pointed out in the *Note* to *Mucilago Chondri* (F. 275).

185. GLYCERITUM BISMUTHI. *N. F.*

Glycerite of Bismuth.

Liquor Bismuthi Concentratus. Concentrated Solution of Bismuth.

Bismuth and Ammonium Citrate . . **275 Gm.**
Stronger Ammonia Water (U. S. P.),
a sufficient quantity.
Glycerin . . . . . **500 Cc.**
Water, a sufficient quantity
To make . . . . . **1000 Cc.**

Triturate the Bismuth and Ammonium Citrate with *three hundred and fifty* (350) *cubic centimeters* of Water and *two hundred and fifty* (250) *cubic centimeters* of Glycerin, and add to it gradually just enough Stronger Ammonia Water to dissolve the Salt, and to produce a neutral solution. Then add the remainder of the Glycerin and enough Water to make *one thousand* (1000) *cubic centimeters*, and filter.

Each fluidrachm contains 16 *grains of Bismuth and Ammonium Citrate.*

186. GLYCERITUM GUAIACI. *N. F.*

Glycerite of Guaiac.

Guaiac (U. S. P.), in powder . . . . **85 Gm.**
Solution of Potassa (U. S. P.) . . . **65 Cc.**
Glycerin . . . . . **600 Cc.**
Water, a sufficient quantity
To make . . . . . **1000 Cc.**

Mix the Solution of Potassa with *three hundred* (300) *cubic centimeters* of Water, add the powdered Guaiac, and macerate for 24 hours with occasional agitation. Then filter, add the Glycerin and sufficient Water to make *one thousand* (1000) *cubic centimeters.*

187. GLYCERITUM PEPSINI. *N. F.*

Glycerite of Pepsin.

Pepsin (U. S. P.) . . . . . **85 Gm.**
Hydrochloric Acid (U. S. P.) . . . **10 Cc.**
Purified Talcum (F. 395) . . . . . **15 Gm.**
Glycerin . . . . . **500 Cc.**
Water, a sufficient quantity
To make . . . . . **1000 Cc.**

Mix the Pepsin with *four hundred and fifty* (450) *cubic centimeters* of Water and the Hydrochloric Acid, and agitate until solution has been effected. Then incorporate the Purified Talcum with the liquid, filter, returning the first portions of the filtrate until it runs through clear, and pass enough Water through the filter to make the filtrate measure *five hundred* (500) *cubic centimeters.* To this add the Glycerin, and mix.

Each fluidrachm represents 5 *grains of Pepsin* (*U. S. P.*).

188. GLYCERITUM PICIS LIQUIDÆ. *N. F.*

Glycerite of Tar.

Tar . . . . . **65 Gm.**
Magnesium Carbonate . . . . . **125 Gm.**
Glycerin . . . . . **250 Cc.**
Alcohol . . . . . **125 Cc.**
Water, a sufficient quantity
To make . . . . . **1000 Cc.**

Upon the Tar, contained in a mortar, pour *two hundred* (200) *cubic centimeters* of cold Water, stir them thoroughly together, and pour off the Water. Repeat this once or twice, until the Water only feebly reddens blue litmus-paper. Now triturate the washed Tar with the Alcohol, gradually incorporate the Magnesium Carbonate and Glycerin, and lastly, *six hundred and twenty-five* (625) *cubic centimeters* of Water. Pour the mixture upon a filter of loose texture spread over a piece of straining muslin, and, after the liquid portion has passed through, wash the residue on the filter with Water, until the whole filtrate measures *one thousand* (1000) *cubic centimeters.*

189. GLYCERITUM TRAGACANTHÆ. *N. F.*

Glycerite of Tragacanth.

Tragacanth, in fine powder	125 Gm.
Glycerin	775 Cc.
Water	185 Cc.

Triturate the Tragacanth with the Glycerin in a mortar, add the Water, and continue the trituration, until a homogeneous, thick paste results.

Note.—*Unguentum Glycerin* of the German Pharm. is prepared by triturating 1 part of powdered Tragacanth with 5 parts (by weight) of Alcohol (of about 91 per cent.), then adding 50 parts of Glycerin, and heating on a steam bath.

190. GOSSYPIUM STYPTICUM. *N. F.*

Styptic Cotton.

Purified Cotton (U. S. P.),
Solution of Ferric Chloride (U. S. P.),
Glycerin,
Water, of each . . . . . a sufficient quantity.

Mix the liquids in the proportion of *five* (5) *parts* of the Iron Solution, *one* (1) *part* of Glycerin, and *four* (4) *parts* of Water, in such quantities that the Purified Cotton shall be completely immersed in the liquid when gently pressed. Allow the Cotton to remain in the liquid one hour, then remove it, press it until it has been brought to *twice* its original weight, spread it out in thin layers, in a warm place, protected from dust and light, and when it is sufficiently dry transfer it to well-closed receptacles.

191. INFUSUM BRAYERÆ. *N. F.*

(U. S. P., 1880.)

Infusion of Brayera.

Infusion of Kousso.

Brayera, in No. 20 powder	60 Gm.
Boiling Water	1000 Cc.

Pour the Boiling Water upon the Brayera, and let it macerate in a covered vessel until cool.

This infusion should be dispensed without straining.

192. INFUSUM GENTIANÆ COMPOSITUM FORTIUS. *N. F.*

Stronger Compound Infusion of Gentian.

Gentian	125 Gm.
Coriander	35 Gm.
Bitter Orange Peel	35 Gm.
Diluted Alcohol (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Reduce the drugs to a moderately coarse (No. 40) powder, moisten it with Diluted Alcohol, pack it in a percolator, and percolate with Diluted Alcohol, until *one thousand* (1000) *cubic centimeters* are obtained.

Note.—When *Infusum Gentianæ Compositum* is prescribed, mix 1 volume of this preparation with 3 volumes of water. A little alcohol may be added to clear the Infusion.

193. INFUSUM ROSÆ COMPOSITUM. *N. F.*

Compound Infusion of Rose.

Red Rose	13 Gm.
Diluted Sulphuric Acid (U. S. P.)	9 Cc.
Sugar	40 Gm.
Boiling Water	1000 Cc.

Pour the Boiling Water upon the Rose in a glass or porcelain vessel, add the Acid, cover the vessel, and macerate for an hour. Then dissolve the Sugar in the liquid and strain.

194. IODOFORMUM AROMATISATUM. *N. F.*

Aromatized Iodoform.

Deodorized Iodoform.

Iodoform	96 Gm.
Cumarin	4 Gm.

Mix them intimately by trituration.

Note.—Should cumarin not be available, or should it be objectionable to the patient, the odor of Iodoform may also be more or less masked by many essential oils,—for instance, those of peppermint, cloves, cinnamon, citronella, bergamot, sassafras, eucalyptus, etc. Another efficient covering agent is freshly-roasted and powdered coffee.

The odor of Iodoform may be removed from the hands, or any utensils which it has come in contact with, by washing them with an aqueous solution of tannic acid.

195. LAC FERMENTATUM. *N. F.*

Fermented Milk.

Kumyss.

Cow's Milk, fresh	1000 Cc.
Yeast, semi-liquid	5 Cc.
Sugar	35 Gm.

Dissolve the Sugar in the Milk, contained in a strong bottle, add the Yeast, cork the bottle securely, and keep it at a temperature between 23° and 32° C. (73.4° to 89.6° F.) for six hours; then transfer it to a cold place.

Note.—In place of preparing Kumyss with sweet milk and waiting until it turns sour, the casein may be precipitated at once by the addition of one-third of ready Kumyss to fresh milk. Yeast is not necessary, but Sugar must be added to produce enough Carbonic Acid Gas to cause effervescence.

Kumyss may also be made from sour milk, freed from its crusts of cream, by breaking up the curd by vigorous stirring, and causing alcoholic fermentation by addition of Sugar and Yeast. The cream removed may be replaced by sweet cream.

Kephir-Kumyss is prepared by adding active Kephir grains to fresh milk, kept at a temperature of 70° to 80° F., until the effect of fermentation becomes apparent by the rising of the grains to the surface. The grains may then be strained off, and the milk, which now contains enough Yeast-cells to insure continuance of the fermentation, left to itself in well-corked bottles.

196. LINIMENTUM ACONITI ET CHLOROFORMI. *N. F.*

Liniment of Aconite and Chloroform.

Tincture of Aconite (U. S. P.)	125 Cc.
Chloroform	125 Cc.
Soap Liniment (U. S. P.)	750 Cc.

Mix them.

197. LINIMENTUM AMMONII IODIDI. *N. F.*

Liniment of Ammonium Iodide.

Iodine	4 Gm.
Oil of Rosemary	15 Cc.
Oil of Lavender	15 Cc.
Camphor	30 Gm.
Ammonia Water (U. S. P.)	110 Cc.
Alcohol, a sufficient quantity	
To make	1000 Cc.

Dissolve the Iodine, the Oils, and the Camphor, in *seven hundred and fifty* (750) *cubic centimeters* of Alcohol, then add the Ammonia Water, and lastly, enough Alcohol to make *one thousand* (1000) *cubic centimeters*.

Note.—On standing, the liquid will become colorless, and there will, usually, be a slight precipitate, which may be separated by filtration.

198. LINIMENTUM CANTHARIDIS. *N. F.*

(U. S. P., 1880.)

Cantharides Liniment.

Cantharides, in No. 60 powder	150 Gm.
Oil of Turpentine, a sufficient quantity	
To make	1000 Cc.

Digest the Cantharides with *one thousand* (1000) *cubic centimeters* of Oil of Turpentine, in a closed vessel, by means of a water-bath, for three hours; then strain, and add enough Oil of Turpentine through the strainer to make the liniment measure *one thousand* (1000) *cubic centimeters*.

199. LINIMENTUM IODI. *N. F.*

Iodine Liniment.

Iodine	125 Gm.
Potassium Iodide	50 Gm.

Glycerin	35 Cc.
Water	65 Cc.
Alcohol, a sufficient quantity	
To make	1000 Cc.

Mix *eight hundred* (800) *cubic centimeters* of Alcohol with the other ingredients, and dissolve the solids by agitation. Then add enough alcohol to make *one thousand* (1000) *cubic centimeters*.

Note.—The proportion of the ingredients above given yields a product practically identical with that prescribed by the *British Pharmacopœia*.

200. LINIMENTUM OPII COMPOSITUM. *N. F.*

Compound Liniment of Opium.

Canada Liniment.

Tincture of Opium (U. S. P.)	100 Cc.
Camphor	17.5 Gm.
Alcohol	250 Cc.
Oil of Peppermint	25 Cc.
Ammonia Water (U. S. P.)	375 Cc.
Oil of Turpentine, a sufficient quantity	
To make	1000 Cc.

Dissolve the Camphor and the Oil of Peppermint in the Alcohol, then add the Tincture of Opium, Ammonia Water, and enough Oil of Turpentine to make *one thousand* (1000) *cubic centimeters*. Shake the mixture, whenever any of it is to be dispensed.

Note.—This Liniment will separate a short time after it has been mixed. It may be made somewhat more permanent by adding *twenty-five* (25) *cubic centimeters* of Tincture of Quillaja (U. S. P.) to the Ammonia Water before adding to the mixture.

201. LINIMENTUM PLUMBI SUBACETATIS. *N. F.*

(U. S. P., 1880.)

Liniment of Lead Subacetate.

Solution of Lead Subacetate (U. S. P.)	350 Cc.
Cotton Seed Oil	650 Cc.

Mix them.

202. LINIMENTUM SAPONATO-CAMPHORATUM. *N. F.*

Camphorated Soap Liniment.

Opodeldoc. Solid Opodeldoc.

White Castile Soap, dried and powdered	75 Gm.
Camphor	25 Gm.
Alcohol	950 Cc.
Oil of Thyme	3 Cc.
Oil of Rosemary	6 Cc.
Stronger Ammonia Water (U. S. P.)	50 Cc.

Introduce the Castile Soap, Camphor, and Alcohol into a flask or suitable bottle, and apply a gentle heat until solution is effected, taking care that no loss of Alcohol be incurred by evaporation. Filter the liquid, while hot, into another flask or bottle; warm again, if necessary, to render the contents liquid, add the Oils and Stronger Ammonia Water, and when the whole has been thoroughly mixed, pour it into small dry vials, which should have been previously warmed, and should immediately be corked and cooled.

Note.—The quantity above given is usually divided into 18 to 20 vials. Solid Opodeldoc is directed by the *German Pharm.* to be prepared with soap made from animal fats; but pure, white Castile Soap may be used, provided it has been previously deprived of water. The Stronger Ammonia Water should be of the full strength prescribed by the *U. S. Pharm.*

203. LINIMENTUM TEREBINTHINÆ ACETICUM. *N. F.*

Acetic Turpentine Liniment.

Linimentum Album. Stokes's Liniment. St. John Long's Liniment.

Oil of Turpentine	100 Cc.
Fresh Egg, albumen and yolk	1
Oil of Lemon	4 Cc.
Acetic Acid (U. S. P.)	20 Cc.
Rose Water (U. S. P.)	85 Cc.

Triturate or beat the contents of the Fresh Egg with the Oil of Turpentine and the Oil of Lemon in a mortar until they are thoroughly mixed. Then incorporate the Acetic Acid and Rose Water. Shake the mixture, whenever any of it is to be dispensed.

204. LINIMENTUM TIGLII. *N. F.*

Liniment of Croton Oil.

Linimentum Crotonis (Brit. Ph.).

Croton Oil	12 Cc.
Oil of Cajuput	44 Cc.
Alcohol	44 Cc.

Mix them.

205. LINIMENTUM TIGLII COMPOSITUM. *N. F.*

Compound Croton Oil Liniment.

Croton Oil	20 Cc.
Oil of Sassafras	20 Cc.
Oil of Turpentine	20 Cc.
Olive Oil	40 Cc.

Mix them.

206. LIQUOR ACIDI PHOSPHORICI COMPOSITUS. *N. F.*

Compound Solution of Phosphoric Acid.

Solution of Acid Phosphates.

Bone Ash, in fine powder	1000 Gm.
Sulphuric Acid (sp. gr., 1.830)	780 Gm.
Water	4000 Cc.

Mix the Bone Ash with *one thousand* (1000) *cubic centimeters* of Water, add the Sulphuric Acid, diluted with *two thousand* (2000) *cubic centimeters* of Water, and mix thoroughly with a porcelain or glass stirrer. Now add the remainder of the Water and set the mixture aside for twenty-four hours, stirring occasionally. Then transfer the mixture to a strong muslin strainer, and subject this to a gradual pressure (avoiding contact with metals), so as to express as much of the liquid as possible. Lastly, filter this through paper.

The specific gravity of this solution is about 1.113 at 15° C. (59° F.).

Note.—The quantity of product obtained depends on the degree of force used in pressing. By strong pressure, about 3500 parts may be obtained. If desired, the magma may also be poured in a glass percolator, the neck of which contains a layer of fine quartz sand or asbestos, previously deprived of matters soluble in sulphuric or phosphoric acids. On cautiously pouring water on top, so as not to mix it with the magma, the acid solution will be displaced. But the percolation must be interrupted as soon as the specific gravity of the percolate begins to fall below 1.113. The Sulphuric Acid used in this preparation may be the commercial variety, provided it is free from arsenic, and of a specific gravity not less than 1.830.

207. LIQUOR ALUMINI ACETATIS. *N. F.*

Solution of Aluminum Acetate.

Aluminum Sulphate, crystallized	300 Gm.
Acetic Acid (U. S. P.)	300 Gm.
Calcium Carbonate	130 Gm.
Water	1000 Cc.

Dissolve the Calcium Carbonate in the Acetic Acid mixed with *two hundred* (200) *cubic centimeters* of Water, and the Aluminum Sulphate in *eight hundred* (800) *cubic centimeters*. Mix the two solutions, and allow the mixture to stand for twenty-four hours, agitating occasionally. Then pour off the clear solution and filter.

The Solution contains from 7.5 to 8 per cent. of basic Aluminum Acetate.

Note.—Practically identical with the *Liquor Aluminii Acetici* of the German Pharm.

208. LIQUOR ALUMINI ACETICO-TARTRATIS. *N. F.*

Solution of Aluminum Acetico-Tartrate.

Alum (U. S. P.)	750 Gm.
Sodium Carbonate	700 Gm.
Glacial Acetic Acid (U. S. P.)	150 Gm.
Tartaric Acid	135 Gm.
Water, a sufficient quantity	
To make	1000 Gm.

Dissolve the Alum and the Sodium Carbonate each in *ten thousand* (10,000) *cubic centimeters* of Water, mix the solutions, and wash the precipitate with water, first by decantation, and afterwards on a strainer, until the washings run off tasteless. Allow the precipitate to drain and to shrink in volume by exposure on the strainer. Then transfer it to a tared capsule, add the Glacial Acetic and the Tartaric Acids, and apply heat until solution has been effected. Finally, evaporate the liquid to *one thousand* (1000) *grammes*.

The product contains about 50 per cent. of dry, so-called Aluminum Acetico-Tartrate.

Note.—The dry salt may be obtained by evaporating the solution.

209. LIQUOR AMMONII ACETATIS CONCENTRATUS. *N. F.*

Concentrated Solution of Ammonium Acetate.

Acetic Acid (U. S. P.)	500 Cc.
Ammonium Carbonate, Water, of each, a sufficient quantity	
To make	1000 Cc.

Neutralize the Acetic Acid with a sufficient quantity of Ammonium Carbonate, carefully avoiding an excess. Then add enough Water to make the product measure *one thousand* (1000) *cubic centimeters*.

Note.—The product is of about 3 times the strength of the official *Liquor Ammonii Acetatis*.

Note.—It is not recommended to keep this solution on hand for the preparation of the official *Liquor Ammonii Acetatis*, as this is preferably made freshly when wanted for use. When it is, however, required, or deemed of advantage, to dispense the concentrated solution, it is suggested that it be diluted with Carbonic Acid Water, or be directed to be diluted with this at the time of administration.

210. LIQUOR AMMONII CITRATIS FORTIOR. *N. F.*

Stronger Solution of Ammonium Citrate.

Citric Acid	560 Gm.
Stronger Ammonia Water (U. S. P.), Water, of each, a sufficient quantity	
To make	1000 Cc.

Neutralize the Citric Acid with the Stronger Ammonia Water, and add enough Water to make *one thousand* (1000) *cubic centimeters*. The solution should be kept in bottles free from lead.

Each fluidrachm contains about 40 grains of Ammonium Citrate.

Note.—This Solution is apt to take up notable quantities of lead if kept in bottles made of flint glass.

Liquor Ammonii Citratis (Brit. Pharm.) may be prepared from this solution by mixing 1 volume of it with 4 volumes of Water.

211. LIQUOR AURI ET ARSENI BROMIDI. *N. F.*

Solution of Gold and Arsenic Bromide.

Arsenous Acid	2.5 Gm.
Gold Tribromide	3.25 Gm.
Bromine Water, Distilled Water, of each, a sufficient quantity	
To make	1000 Cc.

Introduce the Arsenous Acid and about *one hundred and thirty-five* (135) *cubic centimeters* of Bromine Water into a flask and heat gently until all free Bromine has disappeared. Then add Bromine Water, *twenty* (20) to *thirty* (30) *drops* at a time, until it will be present in slight excess, or until the solution does not become colorless after some time. Transfer the solution to a porcelain capsule, expel the excess of Bromine with the aid of gentle heat, dilute it with Water to about *nine hundred* (900) *cubic centimeters*, and dissolve in this the Gold Tribromide, adding enough Water to make *one thousand* (1000) *cubic centimeters*.

Ten (10) *minims of this solution contain* $\frac{1}{12}$ *grain of Gold Tribromide and the equivalent of* $\frac{1}{16}$ *grain of Arsenic Tribromide.*

Note.—Bromine Water is made by shaking Bromine with about thirty times its weight of Water occasionally during several hours, and decanting the Water from the undissolved Bromine.

212. LIQUOR BISMUTHI. *N. F.*

Solution of Bismuth.

Liquid Bismuth.

Glycerite of Bismuth (F. 185)	125 Cc.
Alcohol	125 Cc.
Distilled Water	750 Cc.

Mix the Glycerite of Bismuth with the Distilled Water, then add the Alcohol.

Solution of Bismuth may also be prepared in the following manner:

Bismuth and Ammonium Citrate	17.5 Gm.
Alcohol	125 Cc.
Glycerin	65 Cc.
Ammonia Water (U. S. P.), Distilled Water, of each, a sufficient quantity	
To make	1000 Cc.

Dissolve the Bismuth and Ammonium Citrate in *seven hundred and fifty* (750) *cubic centimeters* of Distilled Water, and allow the solution to stand a short time. Should any insoluble matter have deposited, pour off the clear liquid and add just enough Ammonia Water to the residue to dissolve it, or to cause it to retain a faint odor of Ammonia. Then filter the united liquids, add the Alcohol, the Glycerin, and enough Distilled Water to make *one thousand* (1000) *cubic centimeters*.

This preparation should be freshly made when wanted.

Each fluidrachm represents 1 grain of Bismuth and Ammonium Citrate.

213. LIQUOR BROMI. *N. F.*

Solution of Bromine.

Smith's Solution of Bromine.

Bromine	25 Gm.
Potassium Bromide	12.5 Gm.
Water	100 Cc.

Dissolve the Potassium Bromide in the Water contained in a bottle, add the Bromine, and shake the mixture until this is dissolved. Keep the solution in glass-stoppered vials in a dark place.

Note.—As bromine vapor is very injurious to the respiratory passages and destructive to balances, it is often preferable to take the contents of an original bottle of Bromine,—weighing the bottle, both before opening it and after emptying it, in order to ascertain the exact weight of the Bromine contained therein,—and then to use a quantity of Potassium Bromide and of Water proportionate to the quantities above given.

214. LIQUOR CALCIS SULPHURATÆ. *N. F.*

Solution of Sulphurated Lime.

Solution of Oxysulphuret of Calcium. Vleminck's Solution (or *Lotion*).

Lime, freshly slaked	165 Gm.
Sublimed Sulphur	250 Gm.
Water, a sufficient quantity	
To make	1000 Gm.

Mix the slaked Lime with the Sulphur, and add the mixture gradually to *sixteen hundred and fifty* (1650)

grammes of boiling Water. Then boil the whole, under constant stirring, until it is reduced to *one thousand* (1000) *grammes*, strain, and having allowed the solution to become clear by standing in a well-stoppered bottle, decant the clear brown liquid, and keep it in completely filled and well-stoppered bottles.

215. LIQUOR CARMINI. *N. F.*

Solution of Carmine.

Carmine	60 Gm.
Ammonia Water (U. S. P.)	350 Cc.
Glycerin	350 Cc.
Water, a sufficient quantity	
To make	1000 Cc.

Triturate the Carmine to a fine powder in a wedgwood mortar, gradually add the Ammonia Water, and afterwards the Glycerin, under constant trituration. Transfer the mixture to a porcelain capsule, and heat it upon a water-bath, constantly stirring, until the liquid is entirely free from ammoniacal odor. Then cool, and add enough Water to make *one thousand* (1000) *cubic centimeters*.

Note.—The best quality of Carmine, known in commerce as "No. 40," should be used for this preparation.

216. LIQUOR COCCINEUS. *N. F.*

Cochineal Color.

Cochineal, in No. 50 powder	60 Gm.
Potassium Carbonate	30 Gm.
Alum	30 Gm.
Potassium Bitartrate	60 Gm.
Glycerin	500 Cc.
Alcohol	30 Cc.
Water, a sufficient quantity	
To make	1000 Cc.

Triturate the Cochineal intimately with the Potassium Carbonate and *five hundred* (500) *cubic centimeters* of Water. Then add the Alum and Potassium Bitartrate successively, heat the mixture to boiling in a capacious vessel, then set it aside to cool, add to it the Glycerin and Alcohol, filter, and pass enough Water through the filter to make *one thousand* (1000) *cubic centimeters*.

217. LIQUOR ELECTROPOEICUS. *N. F.*

Battery Fluid.

A. For the Carbon and Zinc Battery.

I. For ordinary use.

Sodium Bichromate, in coarse powder	125 Gm.
Sulphuric Acid, commercial	125 Cc.
Water, cold	1000 Cc.

Pour the Sulphuric Acid upon the powdered Bichromate, and stir the mixture occasionally during one hour. Then slowly add the Water.

II. For use with the Galvano-Cautery.

Sodium Bichromate, in coarse powder	140 Gm.
Sulphuric Acid, commercial	300 Cc.
Water, cold	1000 Cc.

Proceed in the same manner as directed under I.

Note.—Sodium Bichromate is more soluble than the potassium salt, and its products of decomposition, in the battery, are also more soluble. As it is also much cheaper, it is now preferred in all large electric laboratories. When it cannot be obtained, Potassium Bichromate may be used in place of it, as heretofore. The two salts may be substituted for each other, weight for weight.

B. For the Leclanché Battery.

Ammonium Chloride	325 Gm.
Water, enough to make	1000 Cc.

Dissolve the salt in the Water.

218. LIQUOR EXTRACTI GLYCYRRHIZÆ. *N. F.*

Solution of Extract of Glycyrrhiza.

Solution of Extract of Liquorice.

Purified Extract of Glycyrrhiza (F. 158)	a sufficient quantity.
Alcohol	125 Cc.
Glycerin	250 Cc.
Water, a sufficient quantity	
To make	1000 Cc.

In a small portion of Purified Extract of Glycyrrhiza, weighed into a tared capsule, determine the amount of water, by drying it to a constant weight. Then take of the Purified Extract a quantity equivalent to *two hundred and fifty* (250) *grammes* of dry extract, dissolve this, on a water-bath, in *two hundred and fifty* (250) *cubic centimeters* of Water, add the Glycerin, and allow the liquid to cool. Lastly, add the Alcohol, and enough Water to make *one thousand* (1000) *cubic centimeters*.

Each fluidrachm represents 15 *grains of dry Extract of Glycyrrhiza.*

219. LIQUOR FERRI HYPOPHOSPHITIS. *N. F.*

Solution of Hypophosphite of Iron.

Solution of Ferric Hypophosphite.

Iron and Ammonium Sulphate (U. S. P.), in perfect crystals	330 Gm.
Sodium Hypophosphite	220 Gm.
Potassium Citrate	215 Gm.
Glycerin	150 Cc.
Water, a sufficient quantity	
To make	1000 Cc.

Dissolve the Iron and Ammonium Sulphate, and the Sodium Hypophosphite, each, in *fifteen hundred* (1500) *cubic centimeters* of Water, and, if necessary, filter each solution. Then mix them, and stir thoroughly; after a few minutes transfer the resulting magma to a close linen or muslin strainer, and wash the precipitate with about *five hundred* (500) *cubic centimeters* of Water. Allow it to drain, and then press it forcibly in the strainer, so as to remove as much of the liquid as possible. Transfer the precipitate from the strainer to a mortar, add to it the Potassium Citrate, and triturate until a perfectly smooth paste results. Then add the Glycerin, and gradually, while stirring, enough Water to make the solution measure *one thousand* (1000) *cubic centimeters*. Place it for several days in a cold place, if convenient; then pour off the clear solution from any precipitate or crystals that may have formed, and keep the solution in small, completely-filled, and well-corked bottles.

Solution of Hypophosphite of Iron (ferric) may also be prepared in the following manner:

Hypophosphite of Iron (F. 183)	165 Gm.
Potassium Citrate	215 Gm.
Glycerin	150 Cc.
Water, a sufficient quantity	
To make	1000 Cc.

Triturate the Hypophosphite of Iron with *three hundred and fifty* (350) *cubic centimeters* of Water to a perfectly smooth mixture, then add the Potassium Citrate and Glycerin, and apply a gentle heat until solution has been effected. Allow the liquid to cool, and add enough Water to make *one thousand* (1000) *cubic centimeters*. Place the solution for several days in a cold place, if convenient; then pour off the clear solution from any precipitate or crystals that may have formed, and keep the solution in small, completely-filled and well-corked bottles.

About 6 minims of this Solution represent 1 *grain of Hypophosphite of Iron* (*ferric*).

220. LIQUOR FERRI IODIDI. *N. F.*

Solution of Ferrous Iodide.

Iron, in the form of fine, bright, and finely-cut wire	200 Gm.
Iodine	664 Gm.
Diluted Hypophosphorous Acid (U. S. P.)	25 Cc.
Distilled Water, a sufficient quantity	
To make	1000 Cc.

Mix the Iron with *seven hundred and fifty* (750) *cubic centimeters* of Distilled Water in a flask, add about one-half of the Iodine, and agitate continuously until the liquid becomes hot. Then moderate the reaction by placing the flask in cold water, or by allowing cold water to flow over it, meanwhile keeping up the agitation. When the reaction has moderated, add the remaining Iodine one-half at a time, and carefully moderate the reaction each time, in the manner above directed. Finally, raise the contents of the flask to boiling, and filter immediately through moistened pure filtering paper (the point of the filter being supported by a pellet of absorbent cotton) into a bottle containing the Diluted Hypophosphorous Acid. When all the liquid has passed, rinse the flask with *thirty-five* (35) *cubic centimeters* of boiling Distilled Water, and pass this through the filter. Cork the bottle and set it aside to cool. Finally, add enough Distilled Water to make the product measure *one thousand* (1000) *cubic centimeters.*

Note.—This solution contains about 85 per cent. of Ferrous Iodide. On mixing 1 volume with 7 volumes of Syrup (U. S. P.), the product will be practically identical with Syrup of Ferrous Iodide (U. S. P.).

221. LIQUOR FERRI OXYSULPHATIS. *N. F.*

Solution of Oxysulphate of Iron.

Ferrous Sulphate	165 Gm.
Nitric Acid (U. S. P.)	165 Gm.
Distilled Water, a sufficient quantity	
To make	1000 Cc.

Dissolve the Ferrous Sulphate in *eight hundred and fifty* (850) *cubic centimeters* of boiling Distilled Water, in a flask, gradually add the Nitric Acid, and continue the heat until the escaping vapors cease to have a nitrous odor. When the reaction is completed, allow the liquid to cool and add enough Distilled Water to make *one thousand* (1000) *cubic centimeters.*

222. LIQUOR FERRI PROTOCHLORIDI. *N. F.*

Solution of Protochloride of Iron.

Solution of Ferrous Chloride.

Iron, in the form of fine, bright, and finely-cut wire	160 Gm.
Hydrochloric Acid (U. S. P.)	625 Gm.
Glycerin	250 Cc.
Diluted Hypophosphorous Acid (U. S. P.)	10 Cc.
Distilled Water, a sufficient quantity	
To make	1000 Cc.

To the Iron, contained in a flask, add *three hundred and fifty* (350) *cubic centimeters* of Distilled Water, and the Hydrochloric Acid, and apply a gentle heat, until effervescence ceases. Then raise the liquid to boiling, keep it at this temperature for a short time so that the Iron may be brought into solution as far as possible, filter the solution through a pellet of absorbent cotton placed in the neck of a funnel, and wash the cotton with a little Distilled Water. Evaporate the filtrate, over a boiling water-bath, until crystals begin to form, and the escaping vapors cease to redden, or only slightly affect, moistened blue litmus paper. Now add the Glycerin and the Diluted Hypophosphorous Acid, continue the heat, if necessary, until a perfect solution is obtained; then transfer the liquid to a graduated bottle, allow it to cool, and add enough Distilled Water to make *one thousand* (1000) *cubic centimeters.*

Each fluidrachm represents about 20 grains of Protochloride of Iron (ferrous chloride).

223. LIQUOR GUTTA-PERCHÆ. *N. F.*

(U. S. P., 1880.)

Solution of Gutta-Percha.

Gutta-Percha, in thin slices	15 Gm.
Commercial Chloroform	100 Cc.
Lead Carbonate, in fine powder	17 Gm.

Add the Gutta-Percha to *seventy-five* (75) *cubic centimeters* of the Chloroform, contained in a bottle, cork it well, and shake it occasionally until the Gutta-Percha is dissolved. Then add the Lead Carbonate, previously mixed with the remainder of the Chloroform, and, having several times shaken the whole together, at intervals of half an hour, set the mixture aside until the insoluble matters have subsided and the solution has become perfectly clear. Lastly, decant the liquid and preserve it in small, cork-stoppered vials.

224. LIQUOR HYDRARGYRI ET POTASSII IODIDI. *N. F.*

Solution of Iodide of Mercury and Potassium.

Solution of Potassium Iodohydrargyrate. Channing's Solution.

Red Mercuric Iodide	10 Gm.
Potassium Iodide	8 Gm.
Distilled Water	1000 Cc.

Dissolve the salts in the Distilled Water.

225. LIQUOR HYPOPHOSPHITUM. *N. F.*

Solution of Hypophosphites.

Calcium Hypophosphite	35 Gm.
Sodium Hypophosphite	20 Gm.
Potassium Hypophosphite	17.5 Gm.
Citric Acid	16 Gm.
Water, a sufficient quantity	
To make	1000 Cc.

Dissolve the salts and the Citric Acid in Water so as to make *one thousand* (1000) *cubic centimeters;* filter, if necessary, and pass enough Water through the filter to restore the original volume.

Each fluidrachm contains 2 grains of Calcium Hypophosphite, 1¼ grain of Sodium Hypophosphite, and 1 grain of Potassium Hypophosphite.

226. LIQUOR IODI CARBOLATUS. *N. F.*

Carbolized Solution of Iodine.

Boulton's Solution. French Mixture.

Compound Tincture of Iodine (U. S. P.)	15 Cc.
Carbolic Acid, liquefied by a gentle heat	5.5 Cc.
Glycerin	165 Cc.
Water, a sufficient quantity	
To make	1000 Cc.

Mix the Glycerin with the Carbolic Acid and Compound Tincture of Iodine, add enough Water to make *one thousand* (1000) *cubic centimeters,* and expose the mixture to sunlight until it has become colorless.

227. LIQUOR IODI CAUSTICUS. *N. F.*

Caustic Solution of Iodine.

Iodine Caustic. Churchill's Iodine Caustic.

Iodine	25 Gm.
Potassium Iodide	50 Gm.
Water	100 Cc.

Dissolve the Potassium Iodide and the Iodine in the Water.

228. LIQUOR MAGNESII BROMIDI. *N. F.*

Solution of Magnesium Bromide.

Diluted Hydrobromic Acid (U. S. P.)	1000 Cc.
Magnesium Carbonate	a sufficient quantity.

Saturate the Diluted Hydrobromic Acid with a sufficient quantity (about *sixty-five* (65) *grammes*) of Magnesium Carbonate. When effervescence has ceased, filter.

Each fluidrachm contains about 7 grains of Magnesium Bromide.

229. LIQUOR MAGNESII SULPHATIS EFFERVESCENS. *N. F.*

Liquor Magnesiæ Effervescens.

Effervescent Solution of Magnesium Sulphate.

Magnesium Sulphate	25 Gm.
Citric Acid	4 Gm.
Syrup of Citric Acid (U. S. P.)	60 Cc.
Potassium Bicarbonate, crystals	2.5 Gm.
Water, a sufficient quantity	
To make	350 Cc.

Dissolve the Magnesium Sulphate and the Citric Acid in *two hundred and fifty* (250) *cubic centimeters* of Water, add the Syrup of Citric Acid, and filter the solution into a strong bottle of about *three hundred and sixty* (360) *cubic centimeters* capacity. Then add enough Water to nearly fill the bottle, drop in the crystals of Potassium Bicarbonate, immediately close the bottle with a cork, and secure it with twine. Lastly, shake the bottle occasionally, until the crystals are dissolved.

230. LIQUOR MORPHINÆ CITRATIS. *N. F.*

Solution of Morphine Citrate.

Morphine (alkaloid)	3.5 Gm.
Citric Acid	3 Gm.
Cochineal	0.1 Gm.
Alcohol	12.5 Cc.
Distilled Water, a sufficient quantity	
To make	100 Cc.

Triturate the solids with the Alcohol and *eighty* (80) *cubic centimeters* of Water; filter and pass enough Distilled Water through the filter to make *one hundred* (100) *cubic centimeters.*

This Solution should not be kept on hand, but prepared only when required.

Each fluidrachm contains 2 grains of Morphine in the form of Citrate.

231. LIQUOR MORPHINÆ HYPODERMICUS. *N. F.*

Hypodermic Solution of Morphine.

Magendie's Solution of Morphine.

Morphine Sulphate	3.5 Gm.
Distilled Water, warm	100 Cc.

Dissolve the Morphine Sulphate in the warm Distilled Water, and filter the solution through a small pellet of absorbent cotton. When the solution is cold, pass a little Distilled Water through the cotton, if necessary, to make the filtrate measure *one hundred* (100) *cubic centimeters.* Keep the Solution in well-stoppered vials, in a dark place.

232. LIQUOR PANCREATICUS. *N. F.*

Pancreatic Solution.

Pancreatin (U. S. P.)	17.5 Gm.
Sodium Bicarbonate	50 Gm.
Glycerin	250 Cc.
Compound Spirit of Cardamom (F. 347)	35 Cc.
Alcohol	35 Cc.
Purified Talcum (F. 395)	15 Gm.
Water, a sufficient quantity	
To make	1000 Cc.

Triturate the Pancreatin and the Sodium Bicarbonate gradually with *six hundred and fifty* (650) *cubic centimeters* of Water; add the Alcohol, Compound Spirit of Cardamom, and Purified Talcum; mix them thoroughly by shaking, and pour the mixture upon a wetted filter, returning the first portions of the filtrate, until it runs off clear. Wash the filter with enough Water to obtain *seven hundred and fifty* (750) *cubic centimeters* of filtrate. To this add the Glycerin.

Each fluidrachm represents 1 *grain of Pancreatin* (*U. S. P.*).

233. LIQUOR PEPSINI. *N. F.*

(U. S. P., 1880.)

Solution of Pepsin.

Saccharated Pepsin (U. S. P.)	40 Gm.
Hydrochloric Acid (U. S. P.)	12 Gm.
Glycerin	325 Cc.
Water	650 Cc.

Dissolve the Saccharated Pepsin in the Water, previously mixed with the Hydrochloric Acid, add the Glycerin, let the mixture stand twenty-four hours, and filter.

234. LIQUOR PEPSINI AROMATICUS. *N. F.*

Aromatic Solution of Pepsin.

Pepsin (U. S. P.)	17.5 Gm.
Oil of Cinnamon	4 Drops.
Oil of Pimenta	4 Drops.
Oil of Cloves	8 Drops.
Purified Talcum (F. 395)	15 Gm.
Alcohol	35 Cc.
Hydrochloric Acid (U. S. P.)	10 Cc.
Glycerin	250 Cc.
Water, a sufficient quantity	
To make	1000 Cc.

Mix the Pepsin with *five hundred* (500) *cubic centimeters* of Water and the Hydrochloric Acid, and shake the mixture frequently until the Pepsin is dissolved. Then add the Oils, previously dissolved in the Alcohol, and the Purified Talcum; mix the whole thoroughly, by agitation, and filter it through a wetted filter, returning the first portions of the liquid until it runs through clear. Pass enough Water through the filter to make the filtrate measure *seven hundred and fifty* (750) *cubic centimeters.* To this add the Glycerin.

Each fluidrachm represents 1 *grain of Pepsin* (*U. S. P.*).

235. LIQUOR PHOSPHORI. *N. F.*

Solution of Phosphorus.

Thompson's Solution of Phosphorus.

Phosphorus	0.07 Gm.
Absolute Alcohol	35 Cc.
Spirit of Peppermint (U. S. P.)	0.5 Cc.
Glycerin	64.5 Cc.

Dissolve the Phosphorus in *thirty* (30) *cubic centimeters* of Absolute Alcohol, in a stoppered vial or test-tube, by immersion in a water-bath and frequent agitation, taking care that any loss of Alcohol, by evaporation, be made up from time to time. Allow the solution to become nearly cold, and then add to it the remainder of the Absolute Alcohol and the Glycerin, previously mixed and slightly warmed. Finally add the Spirit of Peppermint. Keep the Solution in a well-stoppered bottle, in the dark.

Each fluidrachm contains about $\frac{1}{24}$ *grain of Phosphorus.*

Note.—This solution must not be confounded with the Spiritus Phosphori (U. S. P.), which is not intended to be administered as such, but is only to be used in compounding the Elixir or other preparations of phosphorus.

The Phosphorus should be perfectly translucent, cut and weighed under water, and quickly dried with filtering paper before being dropped into the alcohol.

236. LIQUOR PICIS ALKALINUS. *N. F.*

Alkaline Solution of Tar.

Tar	250 Gm.
Potassa	125 Gm.
Water	625 Cc.

Dissolve the Potassa in the Water. Shake the solution with the Tar so that the latter may be dissolved, and strain the solution through muslin.

237. LIQUOR POTASSÆ CHLORATÆ. *N. F.*

Solution of Chlorinated Potassa.

Liquor Potassæ Chlorinatæ. Javelle Water.

Potassium Carbonate	58 Gm.
Chlorinated Lime (U. S. P.)	80 Gm.
Water, a sufficient quantity	
To make	1000 Gm.

Mix the Chlorinated Lime, contained in a tared flask, with *four hundred* (400) *grammes* of Water. Dissolve the Potassium Carbonate in *three hundred* (300) *grammes* of boiling Water, and pour the hot solution into the mixture first prepared. Shake the flask well, stopper it, set it aside to cool, and then add enough Water to make the contents weigh *one thousand* (1000) *grammes*. Allow the suspended matters to subside, and remove the clear solution by means of a siphon, or by straining through muslin. Keep the product in well-stoppered bottles.

Note.—The Chlorinated Lime should not contain less than 25 per cent. of available chlorine.

238. LIQUOR POTASSII ARSENATIS ET BROMIDI. *N. F.*

Solution of Potassium Arsenate and Bromide.

Liquor Arsenii Bromidi. Solution of Bromide of Arsenic. Clemens's Solution.

Arsenous Acid	10 Gm.
Potassium Bicarbonate	10 Gm.
Bromine	15.5 Gm.
Water, a sufficient quantity	
To make	1000 Cc.

Boil the Arsenous Acid with the Potassium Bicarbonate and *one hundred and twenty-five* (125) *cubic centimeters* of Water, until solution is effected. Allow this to cool, add *six hundred and twenty-five* (625) *cubic centimeters* of Water, then the Bromine, and afterwards enough Water to make *one thousand* (1000) *cubic centimeters*. Let the mixture stand a few hours, agitating it occasionally, then filter.

This Solution contains an amount of Arsenic in combination, corresponding to 1 per cent. of Arsenous Acid.

Note.—The title "Solution of Bromide of Arsenic" (*Liquor Arsenii Bromidi*"), which is often applied to Clemens's Solution or similar preparations, is a misnomer, since arsenic bromide cannot exist, as such, in the presence of water, but is split up into hydrobromic and arsenous acids. The proportions of the ingredients, in the formula above given, have been adjusted, as closely as practicable, so as to yield definite compounds,—viz., potassium arsenate and bromide.

239. LIQUOR SACCHARINI. *N. F.*

Solution of Saccharin.

Saccharin	70 Gm.
Sodium Bicarbonate	33 Gm.
Alcohol	250 Cc.
Water, a sufficient quantity	
To make	1000 Cc.

Dissolve the Saccharin and the Sodium Bicarbonate in *six hundred and fifty* (650) *cubic centimeters* of Water, filter the solution, add the Alcohol to the filtrate, and pass enough Water through the filter to make *one thousand* (1000) *cubic centimeters*.

Each fluidrachm represents 4 grains of Saccharin.

240. LIQUOR SERIPARUS. *N. F.*

Liquid Rennet.

Calves' Rennet, fresh	100 Gm.
Sodium Chloride	40 Gm.
Alcohol	200 Cc.
Water	800 Cc.

Dissolve the Sodium Chloride in the Water, add the Alcohol, and macerate in this mixture the Rennet (or the washed mucous membrane of the fresh stomach of a sucking calf), during three days, under frequent agitation. Then filter.

241. LIQUOR SODII ARSENATIS, PEARSON. *N. F.*

Pearson's Solution of Sodium Arsenate.

Sodium Arsenate, in perfect crystals	1 Gm.
Distilled Water	600 Cc.

Dissolve the Sodium Arsenate in the Distilled Water, and filter, if necessary.

Pearson's Solution of Sodium Arsenate may also be prepared as follows:

Solution of Sodium Arsenate (U. S. P.)	10 Cc.
Distilled Water	90 Cc.

Mix the Solution of Sodium Arsenate with the Distilled Water.

This Solution contains about $\frac{1}{10}$ per cent. of anhydrous Sodium Arsenate.

Note.—This preparation should not be confounded with the *Liquor Sodii Arsenatis*, U. S. P., which is ten times stronger than the above preparation. Pearson's Solution is recognized in the French Pharm., under the title *Soluté d'Arsenate de Soude* (or *Solution Arsenicale de Pearson*). It is recommended that Pearson's Solution be dispensed only when expressly designated as "Pearson's."

242. LIQUOR SODII BORATIS COMPOSITUS. *N. F.*

Compound Solution of Sodium Borate.

Dobell's Solution.

Sodium Borate	15 Gm.
Sodium Bicarbonate	15 Gm.
Carbolic Acid, crystallized	3 Gm.
Glycerin	35 Cc.
Water, a sufficient quantity	
To make	1000 Cc.

Dissolve the salts in about *five hundred* (500) *cubic centimeters* of Water, then add the Glycerin, and the Carbolic Acid previously liquefied by warming, and lastly, enough Water to make *one thousand* (1000) *cubic centimeters*.

243. LIQUOR SODII CARBOLATIS. *N. F.*

Solution of Sodium Carbolate.

Phénol Sodique.

Carbolic Acid, crystallized	50 Gm.
Soda (U. S. P.)	3.5 Gm.
Water	46.5 Gm.

Dissolve the Soda in the Water, add the Carbolic Acid, and warm gently until it is dissolved.

This preparation should be made freshly when wanted.

244. LIQUOR SODII CITRATIS. *N. F.*

Solution of Sodium Citrate.

Mistura Sodii Citratis. Saturatio. Potio Riveri (Germ. Pharm.).

Citric Acid	20 Gm.
Sodium Bicarbonate	25 Gm.
Water	1000 Cc.

Dissolve the Citric Acid in the Water contained in a bottle, add the Sodium Bicarbonate, dissolve it by agitation, and immediately stopper the bottle securely.

This preparation should be freshly prepared when wanted for use.

Note.—The German Pharm. directs that, when "Saturatio" is prescribed, without any specification of the ingredients or strength, *Potio Riveri*, represented here by *Liquor Sodii Citratis*, be dispensed.

245. LIQUOR SODII CITRO-TARTRATIS EFFERVESCENS. *N. F.*

Effervescent Solution of Sodium Citro-Tartrate.

(Tartro-Citric Lemonade.)

Sodium Bicarbonate	26 Gm.
Tartaric Acid	24 Gm.
Citric Acid	2 Gm.
Syrup of Citric Acid (U. S. P.)	50 Cc.
Water, a sufficient quantity	
To make	350 Cc.

Dissolve *twenty-four* (24) *grammes* of the Sodium Bicarbonate in *two hundred and fifty* (250) *cubic centimeters* of Water, add the Tartaric and Citric Acids, and, when they are dissolved, the Syrup of Citric Acid. Filter the solution into a strong bottle of about *three hundred and sixty* (360) *cubic centimeters* capacity, and pass enough Water through the filter to make the filtrate measure *three hundred and twenty* (320) *cubic centimeters*. Dissolve the remainder of the Sodium Bicarbonate (2 grammes) in *thirty* (30) *cubic centimeters* of Water, filter the solution, pour it on top of the solution in the bottle, which close immediately with a cork, and secure it with twine. Then shake the bottle.

246. LIQUOR SODII OLEATIS. *N. F.*

Solution of Sodium Oleate.

White Castile Soap, dry and powdered	625 Gm.
Water, a sufficient quantity	
To make	10000 Cc.

Mix the Castile Soap with *twenty-five hundred* (2500) *cubic centimeters* of Water so as to produce a uniform and gelatinous mixture. Then add *sixty-five hundred* (6500) *cubic centimeters* more of Water, apply heat until the Soap is dissolved, allow the liquid to cool, and add enough Water to make it measure *ten thousand* (10,000) *cubic centimeters*.

Note.—This solution is intended to be used in the preparation of Oleates.

247. LIQUOR STRYCHNINÆ ACETATIS. *N. F.*

Solution of Strychnine Acetate.

Hall's Solution of Strychnine.

Strychnine Acetate	2.1 Gm.
Diluted Acetic Acid (U. S. P.)	35 Cc.
Alcohol	250 Cc.
Compound Tincture of Cardamom (U. S. P.)	10 Cc.
Water, a sufficient quantity	
To make	1000 Cc.

Dissolve the Strychnine Acetate in about *five hundred* (500) *cubic centimeters* of Water mixed with the Diluted Acetic Acid, then add the Alcohol, Compound Tincture of Cardamom, and, lastly, enough Water to make *one thousand* (1000) *cubic centimeters*. Allow the mixture to stand a few days, if convenient, and filter.

Each fluidrachm contains $\frac{1}{8}$ *grain of Strychnine Acetate.*

Note.—The Brit. Pharm. directs a *Liquor Strychninæ Hydrochloratis* (with synonyme: *Liquor Strychnisæ*) which is much stronger, and should not be confounded with the above preparation. It should never be dispensed unless expressly designated. It may be prepared by dissolving 1 grain of crystallized Strychnine (alkaloid) in 80 minims of Water with the aid of 2 drops of Diluted Hydrochloric Acid, and then adding 20 minims of Alcohol. The product contains $\frac{1}{8}$ grain of Strychnine in each fluidrachm.

248. LIQUOR ZINCI ET ALUMINI COMPOSITUS. *N. F.*

Compound Solution of Zinc and Aluminum.

Zinc Sulphate	1000 Gm.
Aluminum Sulphate	1000 Gm.
Naphtol	3 Gm.
Oil of Thyme	10 Cc.
Water, a sufficient quantity	
To make	5000 Cc.

Dissolve the Zinc Sulphate and the Aluminum Sulphate in *five thousand* (5000) *cubic centimeters* of Water, by the aid of heat, add the Naphtol and Oil of Thyme, and shake the mixture occasionally, in a stoppered bottle, until it cools. Set it aside for a few days, if convenient, and then pass it through a wetted filter, following it with enough Water to make *five thousand* (5000) *cubic centimeters*.

Note.—The commercial Aluminum Sulphate (*not* Alum) may be used for this preparation. This generally contains a trace of iron, but by allowing the liquid to stand this will be gradually precipitated.

249. LIQUOR ZINCI ET FERRI COMPOSITUS. *N. F.*

Compound Solution of Zinc and Iron.

Deodorant Solution.

Zinc Sulphate	1000 Gm.
Ferrous Sulphate	1000 Gm.
Copper Sulphate	325 Gm.
Naphtol	3 Gm.
Oil of Thyme	10 Cc.
Diluted Hypophosphorous Acid (U. S. P.)	20 Cc.
Water, a sufficient quantity	
To make	5000 Cc.

Dissolve the Zinc Sulphate, Ferrous Sulphate, and Copper Sulphate, in *five thousand* (5000) *cubic centimeters* of boiling Water, add the Naphtol and Oil of Thyme, and shake the mixture occasionally, in a stoppered bottle, until it is cold. Then add the Diluted Hypophosphorous Acid, filter the liquid through a wetted filter, and, lastly, pass enough Water through the filter to make *five thousand* (5000) *cubic centimeters*.

Note.—This solution is used as a simple deodorant and antiseptic for common domestic use, when it is unnecessary or impracticable to employ more powerful agents.

When a deodorant solution is required for purposes where *iron* is objectionable, as, for instance, when woven fabrics are to be steeped in it, the Compound Solution of Zinc and Aluminum (F. 248) may be employed.

250. LIQUOR ZINGIBERIS. *N. F.*

Solution of Ginger.

Soluble Essence of Ginger.

Fluid Extract of Ginger (U. S. P.)	335 Cc.
Pumice, in moderately fine powder	100 Gm.
Water, a sufficient quantity	
To make	1000 Cc.

Pour the fluid Extract of Ginger into a bottle, add to it the Pumice, and shake the mixture thoroughly and repeatedly in the course of several hours. Then add the Water in portions of about *one hundred and twenty-five* (125) *cubic centimeters*, shaking well and frequently after each addition. When all is added, repeat the agitation occasionally during twenty-four hours, then filter, returning the first portions of the filtrate until it runs through clear, and, if necessary, pass enough water through the filter to make *one thousand* (1000) *cubic centimeters*.

251. LOTIO ADSTRINGENS. *N. F.*

Astringent Lotion.

Warren's Styptic.

Sulphuric Acid (U. S. P.)	38 Cc.
Oil of Turpentine	31 Cc.
Alcohol	31 Cc.

To the Sulphuric Acid, contained in a Wedgwood mortar, slowly add the Oil of Turpentine, in small portions at a time, constantly stirring. Allow the mixture to cool, then add the Alcohol cautiously, in the same manner, and continue stirring until no more fumes arise. When the liquid is cold, pour it into a glass-stoppered bottle.

Note.—In preparing this mixture, caution should be used, so that the temperature may not rise too high. Particular care is to be observed, if a larger quantity of this mixture is to be prepared. In this case it is preferable to prepare it in several portions.

252. LOTIO FLAVA. *N. F.*

Yellow Lotion.

Yellow Wash. Aqua Phagedænica Flava.

Corrosive Chloride of Mercury	3 Gm.
Boiling Water,	
Solution of Lime (U. S. P.), of each, a sufficient quantity	
To make	1000 Cc.

Dissolve the Corrosive Chloride of Mercury in *thirty-five* (35) *cubic centimeters* of boiling Water, and add the solution to a sufficient quantity of Solution of Lime to make *one thousand* (1000) *cubic centimeters.*

This mixture should be well agitated whenever any of it is to be dispensed.

253. LOTIO NIGRA. *N. F.*

Black Lotion.

Black Wash. Aqua Phagedænica Nigra.

Mild Chloride of Mercury	7.5 Gm.
Water,	
Solution of Lime (U. S. P.), of each, a sufficient quantity	
To make	1000 Cc.

Triturate the Mild Chloride of Mercury with *thirty-five* (35) *cubic centimeters* of Water, and gradually add a sufficient quantity of Solution of Lime to make *one thousand* (1000) *cubic centimeters.*

This mixture should be well agitated whenever any of it is to be dispensed.

254. LOTIO PLUMBI ET OPII. *N. F.*

Lotion of Lead and Opium.

Lead and Opium Wash.

Lead Acetate	17.5 Gm.
Tincture of Opium (U. S. P.)	35 Cc.
Water, a sufficient quantity	
To make	1000 Cc.

Dissolve the Lead Acetate in about *six hundred and fifty* (650) *cubic centimeters* of Water, add the Tincture of Opium, and enough Water to make *one thousand* (1000) *cubic centimeters.*

This mixture should be well agitated whenever any of it is to be dispensed.

255. MISTURA ACACIÆ. *N. F.*

Mixture of Acacia.

Mixtura Gummosa (Germ. Pharm. I.).

Acacia, in coarse powder	75 Gm.
Sugar	75 Gm.
Water	850 Cc.

Dissolve the Acacia and Sugar in the Water.

This preparation should be freshly made when wanted.

256. MISTURA ADSTRINGENS ET ESCHAROTICA. *N. F.*

Astringent and Escharotic Mixture.

Villate's Solution.

Solution of Lead Subacetate (U. S. P.)	100 Cc.
Copper Sulphate	65 Gm.
Zinc Sulphate	65 Gm.
Diluted Acetic Acid (U. S. P.)	850 Cc.

Dissolve the Copper Sulphate and Zinc Sulphate in the Diluted Acetic Acid, add the Solution of Lead Subacetate, and agitate thoroughly. Set the mixture aside, so that the precipitate may subside. Then decant, or siphon off, the clear liquid and preserve it for use.

Note.—In attempting to pass the liquid through a filter, it will usually be found that the finely divided precipitate of lead sulphate will partially pass along with it. This may be prevented (in this and many similar cases) by adding to the mixture a small quantity of starch, thoroughly incorporating this by agitation, and pouring the mixture on the previously wetted filter. The first portions of the filtrate are poured back until it runs through clear.

257. MISTURA AMMONII CHLORIDI. *N. F.*

Mixture of Ammonium Chloride.

Mistura (or *Mixtura*) *Solvens Simplex.*

Ammonium Chloride	25 Gm.
Purified Extract of Glycyrrhiza (F. 158)	25 Gm.
Water, a sufficient quantity	
To make	1000 Cc.

Dissolve the solids in a sufficient quantity of Water to make *one thousand* (1000) *cubic centimeters.*

Note.—Sometimes a *Mistura* (or *Mixtura*) *Solvens Stibiata* is prescribed. This may be prepared by dissolving *thirty centigrammes* (0.30 Gm.) of Antimony and Potassium Tartrate in *one thousand* (1000) *cubic centimeters* of *Mistura Ammonii Chloridi.*

258. MISTURA CAMPHORÆ ACIDA. *N. F.*

Acid Camphor Mixture.

Mistura Antidysenterica. Hope's Mixture.

Nitric Acid (U. S. P.)	17.5 Cc.
Tincture of Opium (U. S. P.)	12 Cc.
Camphor Water (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Mix the Nitric Acid with about *five hundred* (500) *cubic centimeters* of Camphor Water, add the Tincture of Opium, and, lastly, enough Camphor Water to make *one thousand* (1000) *cubic centimeters.*

259. MISTURA CAMPHORÆ AROMATICA. *N. F.*

Aromatic Camphor Mixture.

Parrish's Camphor Mixture.

Compound Tincture of Lavender (U. S. P.)	250 Cc.
Sugar	35 Gm.
Camphor Water (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Mix the Compound Tincture of Lavender with about *five hundred* (500) *cubic centimeters* of Camphor Water, dissolve the Sugar in the mixture, and add enough Camphor Water to make *one thousand* (1000) *cubic centimeters.*

260. MISTURA CARMINATIVA. *N. F.*

Carminative Mixture.

Dalby's Carminative.

Magnesium Carbonate	65 Gm.
Potassium Carbonate	3 Gm.
Tincture of Opium (U. S. P.)	25 Cc.
Oil of Caraway	0.5 Cc.
Oil of Fennel	0.5 Cc.
Oil of Peppermint	0.5 Cc.
Syrup (U. S. P.)	160 Cc.
Water, a sufficient quantity	
To make	1000 Cc.

Triturate the Oils with about *ten* (10) *grammes* of Magnesium Carbonate, and *seven hundred and fifty* (750) *cubic centimeters* of Water gradually added. Then add the remainder of the Magnesium Carbonate and the other

ingredients, and, lastly, add enough Water to make *one thousand* (1000) *cubic centimeters.*

This preparation should be freshly made when wanted.

Each fluidounce represents about 1 grain of Opium.

261. MISTURA CHLORALI ET POTASII BROMIDI COMPOSITA. *N. F.*

Compound Mixture of Chloral and Potassium Bromide.

Chloral (U. S. P.)	250 Gm.
Potassium Bromide	250 Gm.
Extract of Indian Cannabis (U. S. P.)	2 Gm.
Extract of Hyoscyamus (U. S. P.)	2 Gm.
Alcohol	60 Cc.
Tincture of Quillaja (U. S. P.)	65 Cc.
Water, a sufficient quantity	
To make	1000 Cc.

Dissolve the Chloral and Potassium Bromide in *six hundred* (600) *cubic centimeters* of Water, dissolve in this solution the Extract of Hyoscyamus, and add the Tincture of Quillaja. Then dissolve the Extract of Indian Cannabis in the Alcohol, and add this solution gradually, and under shaking, to that first prepared. Finally, add enough Water to make *one thousand* (1000) *cubic centimeters.*

This preparation should be shaken whenever any of it is to be dispensed.

Each fluidrachm contains 15 grains each of Chloral and of Potassium Bromide, and ⅛ grain each of Extract of Indian Cannabis and of Extract of Hyoscyamus.

262. MISTURA CHLOROFORMI ET CANNABIS INDICÆ COMPOSITA. *N. F.*

Compound Mixture of Chloroform and Cannabis Indica.

Chloroform Anodyne.

Chloroform	125 Cc.
Ether	35 Cc.
Tincture of Indian Cannabis (U. S. P.)	125 Cc.
Tincture of Capsicum (U. S. P.)	65 Cc.
Morphine Sulphate	2.5 Gm.
Oil of Peppermint	2 Cc.
Glycerin	125 Cc.
Water	65 Cc.
Alcohol, a sufficient quantity	
To make	1000 Cc.

Dissolve the Oil of Peppermint in *five hundred* (500) *cubic centimeters* of Alcohol, add the Chloroform, Ether, and the Tinctures. Mix well, and add the Morphine Sulphate, previously dissolved in the Water and Glycerin. Finally, add enough Alcohol to make *one thousand* (1000) *cubic centimeters.*

Each fluidrachm represents about 7½ minims of Chloroform, 7½ minims of Tincture of Indian Cannabis, 3¾ minims of Tincture of Capsicum, and ¼ of a grain of Morphine Sulphate.

263. MISTURA CONTRA DIARRHŒAM. *N. F.*

Diarrhœa Mixture.

Cholera Mixture.

1. Tincture of Opium (U. S. P.),
Tincture of Capsicum (U. S. P.),
Tincture of Rhubarb (U. S. P.),
Spirit of Camphor (U. S. P.),
Spirit of Peppermint (U. S. P.), of each . . . . . 20 Cc.

Mix them, and filter.

Note.—The formula above given, which appears to be that in most general use, is also known under the name of "Sun Mixture."

Of other similar preparations, in more or less general use, the following may be mentioned here:

2. *Loomis's Diarrhœa Mixture.*

Tincture of Opium (U. S. P.)	12.5 Cc.
Tincture of Rhubarb (U. S. P.)	12.5 Cc.
Compound Tincture of Catechu (U. S. P.)	25 Cc.
Oil of Sassafras	1 Cc.
Compound Tincture of Lavender (U. S. P.)	49 Cc.

3. *Squibb's Diarrhœa Mixture.*

Tincture of Opium (U. S. P.)	20 Cc.
Tincture of Capsicum (U. S. P.)	20 Cc.
Spirit of Camphor (U. S. P.)	20 Cc.
Chloroform (U. S. P.)	7.5 Cc.
Alcohol	32.5 Cc.

4. *Thielemann's Diarrhœa Mixture.*

Wine of Opium (U. S. P.)	25 Cc.
Tincture of Valerian (U. S. P.)	37.5 Cc.
Ether (U. S. P.)	12.5 Cc.
Oil of Peppermint	3 Cc.
Fluid Extract of Ipecac (U. S. P.)	0.75 Cc.
Alcohol	21.25 Cc.

This preparation is practically identical with the *Mistura Thielemanni* of the Swedish Pharm.

5. *Velpeau's Diarrhœa Mixture.*

Tincture of Opium (U. S. P.),
Compound Tincture of Catechu (U. S. P.),
Spirit of Camphor (U. S. P.), of each . . 33.33 Cc.

264. MISTURA COPAIBÆ COMPOSITA. *N. F.*

Compound Copaiba Mixture.

1. *Lafayette Mixture.*

Copaiba	125 Cc.
Spirit of Nitrous Ether (U. S. P.)	125 Cc.
Compound Tincture of Lavender (U. S. P.)	125 Cc.
Solution of Potassa (U. S. P.)	35 Cc.
Syrup (U. S. P.)	325 Cc.
Mucilage of Dextrin (F. 277), a sufficient quantity	
To make	1000 Cc.

Mix the Copaiba with the Solution of Potassa and the Spirit of Nitrous Ether. Then add the Compound Tincture of Lavender, and, lastly, the Syrup and Mucilage of Dextrin. Mix the whole thoroughly by shaking.

This mixture should be well agitated whenever any of it is to be dispensed.

Each fluidrachm contains 7½ minims of Copaiba.

Note.—The above mixture has usually been, and may be, prepared with Mucilage of Acacia; but if Mucilage of Dextrin be used, it will keep for a longer time without separating.

A mixture of somewhat similar composition, in considerable use in some parts of the country, is the following:

2. *Chapman's Mixture.*

Copaiba	250 Cc.
Spirit of Nitrous Ether (U. S. P.)	250 Cc.
Compound Tincture of Lavender (U. S. P.)	65 Cc.
Tincture of Opium (U. S. P.)	30 Cc.
Mucilage of Acacia (U. S. P.)	125 Cc.
Water, a sufficient quantity	
To make	1000 Cc.

265. MISTURA EXPECTORANS, STOKES. *N. F.*

Stokes's Expectorant Mixture.

Stokes's Expectorant.

Ammonium Carbonate	17.5 Gm.
Fluid Extract of Senega (U. S. P.)	35 Cc.
Fluid Extract of Squill (U. S. P.)	35 Cc.
Camphorated Tincture of Opium (U. S. P.)	175 Cc.
Water	100 Cc.
Syrup of Tolu (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Dissolve the Ammonium Carbonate in the Water, add the Fluid Extracts and Tincture, and, lastly, enough Syrup of Tolu to make *one thousand* (1000) *cubic centimeters.*

266. MISTURA GUAIACI. *N. F.*

Mixture of Guaiac.

Guaiac (U. S. P.), in powder	25 Gm.
Sugar	25 Gm.
Acacia, in fine powder	15 Gm.
Cinnamon Water (U. S. P.)	1000 Cc.

Triturate the powdered Guaiac with the Sugar and Acacia, then gradually add the Cinnamon Water, and mix thoroughly.

This mixture should be well agitated whenever any of it is to be dispensed.

267. MISTURA MAGNESIÆ ET ASAFŒTIDÆ. *N. F.*

(U. S. P., 1880.)

Mixture of Magnesia and Asafetida.

Dewees's Carminative.

Magnesium Carbonate	50 Gm.
Tincture of Asafetida	75 Cc.
Tincture of Opium	10 Cc.
Sugar	100 Gm.
Distilled Water, a sufficient quantity	
To make	1000 Cc.

Rub the Magnesium Carbonate and Sugar, in a mortar, with the Tincture of Asafetida and the Tincture of Opium. Then gradually add enough Distilled Water to make the mixture measure *one thousand* (1000) *cubic centimeters.*

268. MISTURA OLEO-BALSAMICA. *N. F.*

Oleo-balsamic Mixture.

Mixtura Oleoso-balsamica (Germ. Pharm.). *Balsamum Vitæ Hoffmanni.*

Oil of Lavender	4 Cc.
Oil of Thyme	4 Cc.
Oil of Lemon	4 Cc.
Oil of Mace	4 Cc.
Oil of Orange Flowers	4 Cc.
Oil of Cloves	3.5 Cc.
Oil of Cinnamon	3.5 Cc.
Balsam of Peru	10.5 Cc.
Alcohol, a sufficient quantity	
To make	1000 Cc.

Dissolve the Oils and the Balsam of Peru in the Alcohol, let the solution stand a few days, and then filter.

269. MISTURA OLEI PICIS. *N. F.*

Mixture of Oil of Tar.

Mistura Picis Liquidæ. Tar Mixture.

Purified Extract of Glycyrrhiza (F. 158)	65 Gm.
Oil of Tar (U. S. P.)	35 Cc.
Sugar	250 Gm.
Chloroform (U. S. P.)	10 Cc.
Oil of Peppermint	3 Cc.
Alcohol	160 Cc.
Water, a sufficient quantity	
To make	1000 Cc.

Add the Purified Extract of Glycyrrhiza and Sugar to *six hundred* (600) *cubic centimeters* of Water, contained in a covered vessel, and heat the mixture to boiling until the Extract and Sugar are dissolved. Then add the Oil of Tar, cover the vessel, and allow the contents to cool, stirring occasionally. Next add the Chloroform and Oil of Peppermint previously dissolved in the Alcohol, and, lastly, enough Water to make *one thousand* (1000) *cubic centimeters.*

This mixture should be well agitated whenever any of it is to be dispensed.

270. MISTURA RHEI COMPOSITA. *N. F.*

Compound Mixture of Rhubarb.

Squibb's Rhubarb Mixture.

Fluid Extract of Rhubarb (U. S. P.)	12 Cc.
Fluid Extract of Ipecac (U. S. P.)	2 Cc.
Sodium Bicarbonate	24 Gm.
Glycerin	250 Cc.
Peppermint Water (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Dissolve the Sodium Bicarbonate in about *five hundred* (500) *cubic centimeters* of Peppermint Water, then add the Fluid Extracts and Glycerin, and, lastly, enough Peppermint Water to make *one thousand* (1000) *cubic centimeters.*

271. MISTURA SASSAFRAS ET OPII. *N. F.*

Mixture of Sassafras and Opium.

Mistura Opii Alkalina. Godfrey's Cordial.

Oil of Sassafras	1 Cc.
Tincture of Opium (U. S. P.)	35 Cc.
Alcohol	50 Cc.
Potassium Carbonate	8 Gm.
Molasses	325 Cc.
Water, a sufficient quantity	
To make	1000 Cc.

Mix the Tincture of Opium with the Alcohol, in which the Oil of Sassafras has previously been dissolved. Dissolve the Potassium Carbonate in about *five hundred* (500) *cubic centimeters* of Water, mix this with the Molasses, then add the mixture first prepared, and, lastly, enough Water to make *one thousand* (1000) *cubic centimeters.* Allow the mixture to become clear by standing, then pour off the liquid portion and preserve it for use.

Each fluidrachm contains 2 minims of Tincture of Opium, corresponding to about $\frac{1}{5}$ grain of Opium.

272. MISTURA SODÆ ET MENTHÆ. *N. F.*

Mixture of Soda and Spearmint.

Soda Mint.

Sodium Bicarbonate	50 Gm.
Aromatic Spirit of Ammonia (U. S. P.)	10 Cc.
Spearmint Water (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Dissolve the Sodium Bicarbonate in about *seven hundred and fifty* (750) *cubic centimeters* of Spearmint Water, add the Aromatic Spirit of Ammonia and enough Spearmint Water to make *one thousand* (1000) *cubic centimeters.* Filter, if necessary.

273. MISTURA SPLENETICA. *N. F.*

Splenetic Mixture.

Spleen Mixture. Gadberry's Mixture.

Ferrous Sulphate	14 Gm.
Quinine Sulphate	14 Gm.
Nitric Acid (U. S. P.)	14 Cc.
Potassium Nitrate	42 Gm.
Water, a sufficient quantity	
To make	1000 Cc.

Triturate the Ferrous Sulphate, reduced to powder, with the Nitric Acid previously mixed with an equal volume of Water. When effervescence has ceased, warm the mixture gently, until it no longer evolves visible vapors of a yellowish tint. Then add to it the Quinine Sulphate, the Potassium Nitrate, and, lastly, enough Water to make *one thousand* (1000) *cubic centimeters.* When solution has been effected, filter.

274. MISTURA SULPHURICA ACIDA. *N. F.*

Sulphuric Acid Mixture.

Mixtura Sulphurica Acida (Germ. Phar.). *Haller's Acid Elixir.*

Sulphuric Acid (U. S. P.)	250 Gm.
Alcohol, a sufficient quantity	
To make	1000 Gm.

Add the Acid very gradually to *seven hundred and fifty* (750) *grammes* of Alcohol, contained in a flask, agitating after each addition, and taking care that the temperature of the mixture be not allowed to rise above 50° C. (122° F.). When the mixture is cold, add enough Alcohol, if necessary, to make *one thousand* (1000) *grammes*.

Note.—The same product may be obtained, approximately, by carefully and slowly adding 1 volume of Sulphuric Acid to 7 volumes of Alcohol, and this method may be used when small quantities are required for immediate use in a prescription.

275. MUCILAGO CHONDRI. *N. F.*

Mucilage of Irish Moss.

Irish Moss	30 Gm.
Water, a sufficient quantity	
To make	1000 Cc.

Wash the Irish Moss with cold Water, then place it in a suitable vessel, add *one thousand* (1000) *cubic centimeters* of Water, and heat it on a water-bath, boiling for fifteen minutes, frequently stirring. Then strain it through muslin, and pass enough Water through the strainer to make the liquid, when cold, measure *one thousand* (1000) *cubic centimeters*.

Mucilage of Irish Moss may also be prepared in the following manner:

Irish Moss Gelatin (F. 184)	20 Gm.
Water, a sufficient quantity	
To make	1000 Cc.

Heat the Irish Moss Gelatin with *one thousand* (1000) *cubic centimeters* of Water, at a boiling temperature, until it is completely dissolved. Then allow the solution to cool, and add enough Water, if necessary, to make up the volume to *one thousand* (1000) *cubic centimeters*.

Note.—Mucilage of Irish Moss, thus prepared, is well adapted for the preparation of emulsions of fixed oils. If it is, however, required for admixture with *clear* liquids, it should be diluted, when freshly made, and while still hot, with about 3 volumes of boiling water, filtered, and the filtrate evaporated to the volume corresponding to the proportions above given. The filtration may be greatly facilitated by filling the filter loosely with absorbent cotton, and pouring the liquid upon the latter.

276. MUCILAGO CYDONII. *N. F.*

(U. S. P., 1880.)

Mucilage of Cydonium.

Mucilage of Quince Seed.

Cydonium	2 Gm.
Distilled Water	100 Cc.

Macerate the Cydonium for half an hour, in a covered vessel, with the Distilled Water, frequently agitating. Then drain the liquid through muslin without pressure.

This preparation should be freshly made when required for use.

277. MUCILAGO DEXTRINI. *N. F.*

Mucilage of Dextrin.

Dextrin	335 Gm.
Water, a sufficient quantity	
To make	1000 Cc.

Mix them in a tared vessel, and heat the mixture, under constant stirring, to near boiling, until the Dextrin is dissolved and a limpid liquid results. Then restore any loss of water by evaporation, strain the liquid through muslin, and allow it to cool short of gelatinizing, when it will be ready for immediate use.

Note.—If the Mucilage is not at once to be used for preparing emulsions or other mixtures, transfer it, while hot, to bottles, which should be filled to the neck. Then pour into each bottle a sufficient quantity of Olive Oil to form a protecting layer, and when the mucilage has gelatinized, securely cork the bottles, and keep them in a cool place, in an upright position.

When gelatinized Mucilage of Dextrin is to be used for the preparation of emulsions or for other mixtures, pour off the protecting layer of oil from the surface, remove the remainder of the oil by a pellet of absorbent cotton, and warm the bottle gently, until the Mucilage is liquefied. Then allow it to cool short of gelatinizing.

The kind of Dextrin suitable for this preparation is the commercial, *white* variety, provided it still contains some unaltered or only partially altered starch, and forms a jelly on cooling, when made into a mucilage after the formula above given. The yellow variety, which is completely soluble in about 2 parts of cold water, will not answer the purpose.

278. MUCILAGO SALEP. *N. F.*

Mucilage of Salep.

Salep, in fine powder	10 Gm.
Cold Water	100 Cc.
Boiling Water	900 Cc.

Place the powdered Salep in a flask containing the Cold Water, and shake until the powder is divided. Then add the Boiling Water, and shake the mixture continuously until it has cooled to 25° C. (77° F.), or below this temperature. The cooling may be hastened by frequent and brief immersion of the flask in cold water.

Mucilage of Salep should be freshly made when wanted.

Note.—If Sugar or Syrup is prescribed in the same mixture with Mucilage of Salep, it is preferable to triturate the required quantity of powdered Salep with either of the former, as the case may be, and then to add rapidly the proportionate amount of Boiling Water.

279. OLEA INFUSA. *N. F.*

Infused Oils.

The Dry Herb, in moderately coarse (No. 40) powder	200 Gm.
Alcohol	150 Gm.
Ammonia Water (U. S. P.)	4 Gm.
Lard Oil	500 Gm.
Cotton-Seed Oil	500 Gm.

Moisten the powdered Herb with a sufficient quantity of the Alcohol and Ammonia Water previously mixed, then pack it tightly into a stone or enamelled iron vessel of suitable capacity, pour on the remainder of the ammoniated Alcohol, cover it well, and allow the mixture to macerate for twenty-four hours. Then add *one hundred and twenty* (120) *grammes* of the mixed Oils, digest, under frequent agitation, during twelve hours, at a temperature between 50° and 60° C. (122° to 140° F.), transfer the mixture to a strainer, and express strongly. To the residue, returned to the vessel, add the remainder of the Oils, digest and express in the same manner, and unite the expressed portions.

280. OLEATUM ACONITINÆ. *N. F.*

Oleate of Aconitine.

Aconitine, alkaloid	2 Gm.
Oleic Acid	98 Gm.

Triturate the Aconitine with a small portion of the Oleic Acid in a mortar, then incorporate the remainder of the Oleic Acid, and stir the mixture frequently until the alkaloid is dissolved.

Note.—The market affords a variety of Aconitines made by different processes, by different manufacturers, and of greatly different potency. Only the pure crystallized or crystallizable alkaloid, prepared by Duquesnel's method, or at least one equal to it in strength, should be used for this preparation.

281. OLEATUM PLUMBI. *N. F.*

Lead Oleate.

Lead Acetate	75 Gm.
Solution of Sodium Oleate (F. 246) .	2000 Cc.
Acetic Acid (U. S. P.),	
Water, each	a sufficient quantity.

Dissolve the Lead Acetate in *four thousand* (4000) *cubic centimeters* of Water. Should the solution be turbid or opalescent, add to it Acetic Acid, in drops, until it has become clear. Then filter it, if necessary, through a pellet of absorbent cotton placed in the neck of a funnel, and mix it slowly, and under constant stirring, with the Solu-

tion of Sodium Oleate. Heat the mixture to boiling, transfer it to a strainer, and when the liquid has drained off, wash the residue with *four thousand* (4000) *cubic centimeters* of boiling Water. Lastly, take the mass from the strainer, remove any occluded Water by pressure, and transfer it, while warm and soft, to suitable vessels.

The product contains an amount of Lead corresponding to about 28 per cent. of Lead Oxide.

Note.—The theoretical yield of Lead Oleate obtainable from 75 grammes of lead acetate is 143 grammes; in practice, about 125 grammes will be obtained. Lead Oleate prepared by the above process is of about the consistence of lead plaster, and may be converted into an ointment by mixing with it such a proportion of oleic acid as may be required.

282. OLEATUM QUININÆ. *N. F.*

Oleate of Quinine.

Quinine (U. S. P.), dried at 100° C. (212° F.) until it ceases to lose weight . . .	25 Gm.
Oleic Acid	75 Gm.

Triturate the Quinine with the Oleic Acid, gradually added, then apply a gentle heat, and stir frequently, until the Quinine is dissolved.

The product contains 25 per cent. of dry Quinine.

Note.—When the official Quinine ($C_{20}H_{24}N_2O_2.3H_2O$) is not available, the quantity corresponding to 25 grammes of dry Quinine may be prepared as follows: Take 34 grammes of official Quinine Sulphate, dissolve it in 200 grammes of Water with the aid of a sufficient quantity of Diluted Sulphuric Acid, then precipitate the Quinine by means of Ammonia Water, added, under constant stirring, until it is in slight excess. Transfer the magma to a close muslin strainer, previously wetted, allow the liquid to drain off, and wash the precipitate with ice-cold Water, until the washings are practically tasteless, but using not more than 200 grammes of Water. Lastly, dry the precipitate.

The theoretical quantity of dry Quinine obtainable from 34 grammes of the Sulphate is 25.27 grammes. In practice, approximately 25 grammes will be obtained.

283. OLEATUM ZINCI. *N. F.*

Zinc Oleate.

Zinc Acetate, crystallized	115 Gm.
Solution of Sodium Oleate (F. 246) .	5000 Cc.
Water	a sufficient quantity.

Dissolve the Zinc Acetate in *ten thousand* (10,000) *cubic centimeters* of cold Water, filter the solution, if necessary, through a pellet of absorbent cotton placed in the neck of a funnel, and then mix it slowly, and under constant stirring, with the Solution of Sodium Oleate. Transfer the mixture to a wetted muslin strainer, and, when the liquid has drained off, wash the precipitate with Water, until the washings are practically tasteless. Lastly, dry the precipitate, spread on paper, by exposure to dust-free air, without heat.

The product contains an amount of Zinc corresponding to about 13 per cent. of Zinc Oxide.

Note.—The theoretical yield of Zinc Oleate obtainable from 115 grammes of zinc acetate is 287.5 grammes; in practice, about 265 grammes will be obtained. Zinc Oleate, prepared by the above process, is in the form of a soft, white powder, and may be converted into a plaster or ointment by mixing it with such a proportion of oleic acid as may be required.

284. OLEOSACCHARA. *N. F.*

Oil-Sugars.

Elæosacchara (Germ. Pharm.).

Any Volatile Oil	1 Drop.
Sugar	2 Gm.

Triturate the Sugar with the Volatile Oil to a fine powder.

This preparation should be freshly made, when wanted.

Note.—When *Elæosaccharum Anisi, E. Fœniculi, E. Menthæ Piperitæ*, etc., etc., are prescribed, these are to be prepared from the corresponding essential oils, according to the above formula.

285. OLEUM CARBOLATUM. *N. F.*

Carbolized Oil.

Carbolic Acid	5 Gm.
Cotton-Seed Oil	95 Gm.

Melt the Carbolic Acid with a gentle heat, and mix it with the Cotton-Seed Oil.

286. OLEUM HYOSCYAMI COMPOSITUM. *N. F.*

Compound Oil of Hyoscyamus.

Balsamum Tranquillans.

Oil of Absinth,	
Oil of Lavender,	
Oil of Rosemary,	
Oil of Sage,	
Oil of Thyme, of each	2 Drops.
Infused Oil of Hyoscyamus (F. 279)	100 Cc.

Mix them.

Note.—Oil of Absinth is the volatile oil of *Artemisia Absinthium* Linné (Wormwood), and Oil of Sage is the volatile oil of *Salvia officinalis* Linné. Infused Oil of Hyoscyamus is the *Oleum Hyoscyami* of the Germ. Pharm.; see under No. 279. The *Beaumé Tranquille* (*Balsamum tranquillans*) of the Codex is a more complex preparation, not identical with the above, but possessing about the same properties.

287. OXYMEL SCILLÆ. *N. F.*

Oxymel of Squill.

Vinegar of Squill (U. S. P.)	50 Gm.
Honey	100 Gm.

Mix them in a tared porcelain capsule or enamelled iron vessel, and apply the heat of a water-bath until the mixture has been reduced to the weight of *one hundred* (100) *grammes*. Then strain, allow it to cool, and transfer it to bottles, which should be well corked.

288. PEPSINUM AROMATICUM. *N. F.*

Aromatic Pepsin.

Saccharated Pepsin (U. S. P.) . . .	97 Gm.
Aromatic Fluid Extract (U. S. P.) .	6 Cc.
Tartaric Acid	1.5 Gm.
Sodium Chloride	1.5 Gm.

Mix the ingredients by trituration, dry the product by exposure to warm air, and keep it in well-stoppered bottles.

289. PILULÆ. *N. F.*

Pills.

In giving the formulas for Pills, the quantities of the several ingredients required for *one hundred* (100) *pills* are given in Metric Weights in the first column, while the quantities required for each *single pill* are given in Apothecaries' Weight in the second column. When it is desirable to prepare a number of pills by the proportion given for the *single pill*, it is recommended that upon multiplying by the number of pills required, the nearest whole number, or nearest convenient fraction, in each case, be chosen.

290. PILULÆ AD PRANDIUM. *N. F.*

Dinner Pills.

1. When "Dinner Pills," under this or some other equivalent name, are prescribed without further specification, it is recommended that the *Pilulæ Aloes et Mastiches* of the U. S. P., also called Lady Webster's Dinner Pills, be dispensed.

Note.—Of other combinations, bearing similar names, or used for similar purposes, the following appear to be those most commonly in use:

2. *Chapman's Dinner Pill.*

	One hundred (100) *pills contain:*	*Each pill contains:*
Purified Aloes (U. S. P.)	9.7 Gm.	1½ grains.
Mastic	9.7 Gm.	1½ grains.
Ipecac, in fine powder	6.5 Gm.	1 grain.
Oil of Fennel	1.5 Cc.	about ¼ minim.

3. *Cole's Dinner Pill.*

	One hundred (100) *pills contain:*	*Each pill contains:*
Purified Aloes (U. S. P.)	7.8 Gm.	1¼ grains.
Mass of Mercury (U. S. P.)	7.8 Gm.	1¼ grains.
Jalap, in fine powder	7.8 Gm.	1¼ grains.
Antimony and Potassium Tartrate	0.13 Gm.	⅒ grain.

4 *Hall's Dinner Pill.*

	One hundred (100) pills contain:	*Each pill contains:*
Purified Aloes (U. S. P.)	6.5 Gm.	1 grain.
Extract of Glycyrrhiza	6.5 Gm.	1 grain.
Soap, in powder	6.5 Gm.	1 grain.
Molasses	6.5 Gm.	1 grain.

291. PILULÆ ALOES ET PODOPHYLLI COMPOSITÆ. *N. F.*

Compound Pills of Aloes and Podophyllum.

Janeway's Pills.

	One hundred (100) pills contain:	*Each pill contains:*
Purified Aloes (U. S. P.)	6.5 Gm.	1 grain.
Resin of Podophyllum (U. S. P.)	3.25 Gm.	½ grain.
Alcoholic Extract of Belladonna Leaves (U. S. P.)	1.6 Gm.	¼ grain.
Extract of Nux Vomica (U. S. P.)	1.6 Gm.	¼ grain.

292. PILULÆ ALOINI COMPOSITÆ. *N. F.*

Compound Pills of Aloin.

	One hundred (100) pills contain:	*Each pill contains:*
Aloin	3.25 Gm.	½ grain.
Resin of Podophyllum (U. S. P.)	0.8 Gm.	⅛ grain.
Alcoholic Extract of Belladonna Leaves (U. S. P.)	1.6 Gm.	¼ grain.

293. PILULÆ ALOINI, STRYCHNINÆ, ET BELLADONNÆ. *N. F.*

Pills of Aloin, Strychnine, and Belladonna.

	One hundred (100) pills contain:	*Each pill contains:*
Aloin	1.3 Gm.	⅕ grain.
Strychnine, alkaloid	0.05 Gm.	1/120 grain.
Alcoholic Extract of Belladonna Leaves (U. S. P.)	0.8 Gm.	⅛ grain.

Note.—These pills are also prepared with double the amount of Strychnine. It is recommended that the stronger pills be dispensed only when specially demanded.

294. PILULÆ ALOINI, STRYCHNINÆ, ET BELLADONNÆ COMPOSITÆ. *N. F.*

Compound Pills of Aloin, Strychnine, and Belladonna.

	One hundred (100) pills contain;	*Each pill contains:*
Aloin	1.3 Gm.	⅕ grain.
Strychnine, alkaloid	0.05 Gm.	1/120 grain.
Alcoholic Extract of Belladonna Leaves (U. S. P.)	0.8 Gm.	⅛ grain.
Extract of Rhamnus Purshiana	3.25 Gm.	½ grain.

Note.—These pills are also prepared with double the amount of Strychnine. It is recommended that the stronger pills be dispensed only when specially demanded.

295. PILULÆ ANTIDYSPEPTICÆ. *N. F.*

Antidyspeptic Pills.

	One hundred (100) pills contain:	*Each pill contains:*
Strychnine, alkaloid	0.16 Gm.	1/100 grain.
Ipecac, in fine powder	0.65 Gm.	1/10 grain.
Alcoholic Extract of Belladonna Leaves (U. S. P.)	0.65 Gm.	1/10 grain.
Mass of Mercury (U. S. P.)	13 Gm.	2 grains.
Compound Extract of Colocynth (U. S. P.)	13 Gm.	2 grains.

296. PILULÆ ANTINEURALGICÆ. *N. F.*

Antineuralgic Pills.

1. *Gross's Antineuralgic Pills.*

	One hundred (100) pills contain:	*Each pill contains:*
Quinine Sulphate	13 Gm.	2 grains.
Morphine Sulphate	0.32 Gm.	1/10 grain.
Strychnine, alkaloid	0.22 Gm.	1/30 grain.
Arsenous Acid	0.32 Gm.	1/10 grain.
Extract of Aconite Leaves (U.S.P., 1870)	3.2 Gm.	½ grain.

Note.—When "Antineuralgic Pills," or "Neuralgia Pills," without other specification, are prescribed, it is recommended that the above preparation be dispensed. Sometimes the Morphine Sulphate is directed to be omitted.

2. *Brown-Séquard's Antineuralgic* (or *Neuralgia*) *Pills* have the following composition:

	One hundred (100) pills contain:	*Each pill contains:*
Extract of Hyoscyamus (U. S. P.)	4.5 Gm.	¾ grain.
Extract of Conium (U. S. P.)	4.5 Gm.	¾ grain.
Extract of Ignatia (U. S. P.)	3.2 Gm.	½ grain.
Extract of Opium (U. S. P.)	3.2 Gm.	½ grain.
Extract of Aconite Leaves (U. S. P., 1870)	2.2 Gm.	⅓ grain.
Extract of Indian Cannabis (U.S.P.)	1.6 Gm.	¼ grain.
Extract of Stramonium (U. S. P.)	1.3 Gm.	⅕ grain.
Alcoholic Extract of Belladonna Leaves (U. S. P.)	1.1 Gm.	⅛ grain.

297. PILULÆ ANTIPERIODICÆ. *N. F.*

Antiperiodic Pills.

Warburg's Pills.

1. *With Aloes:*

	One hundred (100) pills contain:	*Each pill contains:*
Extract of Aloes (U. S. P.)	6.5 Gm.	1 grain.
Rhubarb	3.2 Gm.	½ grain.
Angelica, seed	3.2 Gm.	¼ grain.
Elecampane	1.6 Gm.	¼ grain.
Saffron	1.6 Gm.	¼ grain.
Fennel	1.6 Gm.	¼ grain.
Zedoary, root	0.8 Gm.	⅛ grain.
Cubebs	0.8 Gm.	⅛ grain.
Myrrh	0.8 Gm.	⅛ grain.
White Agaric	0.8 Gm.	⅛ grain.
Camphor	0.8 Gm.	⅛ grain.
Quinine Sulphate	9 Gm.	1½ grains.
Extract of Gentian (U. S. P.)	a sufficient quantity.	a sufficient quantity.

Reduce the drugs to a fine, uniform powder, and make this into pills, by means of Extract of Gentian, in accordance with the formula above given.

2. *Without Aloes:*

Prepare the pills in the same manner as directed in the previous formula, but omit the Extract of Aloes.

Note.—These pills have been introduced for the purpose of facilitating the administration of Warburg's Tincture in a solid form. When "Warburg's Pills," or "Pills of Warburg's Tincture," are prescribed, without further specification, those containing Aloes should be dispensed. Those without Aloes should be furnished only when they are expressly demanded.

Each Warburg's Pill represents about 1 fluidrachm of Warburg's Tincture, with or without Aloes, respectively (see *Tinctura Antiperiodica*, F. 400).

298. PILULÆ COLOCYNTHIDIS COMPOSITÆ. *N. F.*

Compound Pills of Colocynth.

Pilulæ Coccie. Cochia Pills.

	One hundred (100) pills contain:	*Each pill contains:*
Extract of Colocynth (U. S. P.)	1.1 Gm.	⅛ grain.
Purified Aloes (U. S. P.)	13 Gm.	2 grains.
Resin of Scammony (U. S. P.)	13 Gm.	2 grains.
Oil of Cloves	1.5 Cc.	¼ minim.

Note.—The *Pilula Colocynthidis Composita* of the Brit. Pharm., for which the above is an equivalent, is prepared with Colycynth Pulp, and contains Potassium Sulphate, which was originally added as an aid to reduce the ingredients to powder. With the use of Extract of Colocynth, this becomes unnecessary.

The Brit. Pharm. directs the above to be kept as a pill-mass, to be made into pills of such weight as may be prescribed. When such specification is omitted, it is recommended to dispense pills containing the quantities above directed.

299. PILULÆ COLOCYNTHIDIS ET HYOSCYAMI. *N. F.*

Pills of Colocynth and Hyoscyamus.

	One hundred (100) pills contain:	*Each pill contains:*
Extract of Colocynth (U. S. P.)	0.65 Gm.	$\frac{1}{10}$ grain.
Purified Aloes (U. S. P.)	9.7 Gm.	$1\frac{1}{2}$ grains.
Resin of Scammony (U. S. P.)	9.7 Gm.	$1\frac{1}{2}$ grains.
Oil of Cloves	1 Cc.	$\frac{1}{3}$ minim.
Extract of Hyoscyamus (U. S. P.)	9.7 Gm.	$1\frac{1}{2}$ grains.

Note.—The *Pilula Colocynthidis et Hyoscyami* of the Brit. Pharm. is directed to be made by mixing 2 parts of Compound Pill of Colocynth (F. 298) with 1 part of Extract of Hyoscyamus, and is directed to be kept as a pill-mass, to be made into pills of such weight as may be directed. When such specification is omitted, it is recommended to dispense pills containing the quantities above directed.

300. PILULÆ COLOCYNTHIDIS ET PODOPHYLLI. *N. F.*

Pills of Colocynth and Podophyllum.

	One hundred (100) pills contain:	*Each pill contains:*
Compound Extract of Colocynth (U. S. P.)	16.2 Gm.	$2\frac{1}{2}$ grains.
Resin of Podophyllum (U. S. P.)	1.6 Gm.	$\frac{1}{4}$ grain.

301. PILULÆ FERRI COMPOSITÆ. *N. F.*

(U. S. P., 1880.)

Compound Pills of Iron.

	One hundred (100) pills contain:	*Each pill contains:*
Myrrh	9.75 Gm.	$1\frac{1}{2}$ grains.
Sodium Carbonate	4.85 Gm.	$\frac{3}{4}$ grain.
Ferrous Sulphate	4.85 Gm.	$\frac{3}{4}$ grain.
Syrup	a sufficient quantity.	

302. PILULÆ GALBANI COMPOSITÆ. *N. F.*

(U. S. P., 1880.)

Compound Pills of Galbanum.

	One hundred (100) pills contain:	*Each pill contains:*
Galbanum	9.75 Gm.	$1\frac{1}{2}$ grains.
Myrrh	9.75 Gm.	$1\frac{1}{2}$ grains.
Asafetida	3.25 Gm.	$\frac{1}{2}$ grain.
Syrup	a sufficient quantity.	

303. PILULÆ GLONOINI. *N. F.*

Pills of Glonoin.

Pills of Nitroglycerin.

Spirit of Glonoin (U. S. P.)	6.5 Gm.
Althæa, in fine powder	6.5 Gm.
Confection of Rose (U.S.P.)	a sufficient quantity.

Mix the Spirit of Glonoin intimately with the powdered Althæa, expose the mixture for a short time to the air, so that the alcohol may evaporate, then make a pill-mass by means of Confection of Rose, and divide it into *one hundred* (100) *pills.*

Each pill contains $\frac{1}{100}$ *grain of Glonoin (Nitroglycerin.*

304. PILULÆ LAXATIVÆ POST PARTUM. *N. F.*

Laxative Pills after Confinement.

Barker's Post-Partum Pills.

	One hundred (100) pills contain:	*Each pill contains:*
Compound Extract of Colocynth (U. S. P.)	11 Gm.	$1\frac{3}{4}$ grains.
Purified Aloes (U. S. P.)	5.5 Gm.	$\frac{5}{8}$ grain.
Extract of Nux Vomica (U. S. P.)	2.5 Gm.	$\frac{5}{12}$ grain.
Resin of Podophyllum (U. S. P.)	0.5 Gm.	$\frac{1}{12}$ grain.
Ipecac, in fine powder	0.5 Gm.	$\frac{1}{12}$ grain.
Extract of Hyoscyamus (U. S. P.)	8 Gm.	$1\frac{1}{4}$ grains.

Note.—This is the formula generally employed by Dr. Fordyce Barker, except where special circumstances render modifications necessary. The formula usually quoted in manufacturers' lists and some formularies is not correct.

305. PILULÆ METALLORUM. *N. F.*

Metallic Pills.

Pilulæ Metallorum Amaræ. Bitter Metallic Pills.

	One hundred (100) pills contain:	*Each pill contains:*
Reduced Iron	6.5 Gm.	1 grain.
Quinine Sulphate	6.5 Gm.	1 grain.
Strychnine, alkaloid	0.32 Gm.	$\frac{1}{20}$ grain.
Arsenous Acid	0.32 Gm.	$\frac{1}{20}$ grain.

Note.—A similar combination is known under the name of *Aitken's Tonic Pills*, as follows:

	One hundred (100) pills contain:	*Each pill contains:*
Reduced Iron	4.5 Gm.	$\frac{3}{4}$ grain.
Quinine Sulphate	6.5 Gm.	1 grain.
Strychnine, alkaloid	0.13 Gm.	$\frac{1}{50}$ grain.
Arsenous Acid	0.13 Gm.	$\frac{1}{50}$ grain.

306. PILULÆ OPII ET CAMPHORÆ. *N. F.*

Pills of Opium and Camphor.

	One hundred (100) pills contain:	*Each pill contains:*
Powdered Opium	6.5 Gm.	1 grain.
Camphor	13 Gm.	2 grains.

307. PILULÆ OPII ET PLUMBI. *N. F.*

Pills of Opium and Lead.

	One hundred (100) pills contain:	*Each pill contains:*
Powdered Opium	6.5 Gm.	1 grain.
Lead Acetate	6.5 Gm.	1 grain.

308. PILULÆ PODOPHYLLI, BELLADONNÆ, ET CAPSICI. *N. F.*

Pills of Podophyllum, Belladonna, and Capsicum.

Squibb's Podophyllum Pills.

	One hundred (100) pills contain:	*Each pill contains:*
Resin of Podophyllum (U. S. P.)	1.6 Gm.	$\frac{1}{4}$ grain.
Alcoholic Extract of Belladonna leaves (U. S. P.)	0.8 Gm.	$\frac{1}{8}$ grain.
Capsicum, in moderately fine powder	3.2 Gm.	$\frac{1}{2}$ grain.
Sugar of Milk, in fine powder	6.5 Gm.	1 grain.
Acacia, in fine powder	1.6 Gm.	$\frac{1}{4}$ grain.
Glycerin, Syrup (U. S. P.), each	a sufficient quantity.	each, a sufficient quantity.

309. PILULÆ QUADRUPLICES. *N. F.*

Quadruplex Pills.

Quatuor Pills. Pilulæ Ferri et Quininæ Compositæ.

	One hundred (100) pills contain:	*Each pill contains:*
Dried Ferrous Sulphate	6.5 Gm.	1 grain.
Quinine Sulphate	6.5 Gm.	1 grain.
Purified Aloes (U. S. P.)	6.5 Gm.	1 grain.
Extract of Nux Vomica (U. S. P.)	1.6 Gm.	¼ grain.
Extract of Gentian (U. S. P.)	a sufficient quantity.	a sufficient quantity.

310. PILULÆ TRIPLICES. *N. F.*

Triplex Pills.

Pilula Triplex.

	One hundred (100) pills contain:	*Each pill contains:*
Purified Aloes (U. S. P.)	13 Gm.	2 grains.
Mass of Mercury (U. S. P.)	6.5 Gm.	1 grain.
Resin of Podophyllum (U. S. P.)	1.6 Gm.	¼ grain.

Note.—When *Pilula Triplex*, under this name or some equivalent, is prescribed without further specification, it is recommended that the above preparation be dispensed. A formula devised by Dr. John W. Francis is also in use, as follows:

Francis's Triplex Pill.

	One hundred (100) pills contain:	*Each pill contains:*
Purified Aloes (U. S. P.)	5.5 Gm.	⅝ grain.
Scammony	5.5 Gm.	⅝ grain.
Mass of Mercury (U. S. P.)	5.5 Gm.	⅝ grain.
Croton Oil	0.32 Cc.	1/20 minim.
Oil of Caraway	1.6 Cc.	¼ minim.
Tincture of Aloes and Myrrh (U. S. P.)	a sufficient quantity.	a sufficient quantity.

311. PULVIS ACACIÆ COMPOSITUS. *N. F.*

Compound Powder of Acacia.

Pulvis Gummosus (Germ. Pharm.).

Acacia, in fine powder	50 Gm.
Glycyrrhiza, in fine powder	34 Gm.
Sugar, in fine powder	16 Gm.

Mix them intimately.

312. PULVIS ACETANILIDI COMPOSITUS. *N. F.*

Compound Powder of Acetanilid.

Acetanilid	50 Gm.
Caffeine	2 Gm.
Tartaric Acid	3 Gm.
Sodium Bicarbonate	45 Gm.

Reduce the ingredients separately to a fine powder and mix them thoroughly.

Note.—This preparation is popularly prescribed in New Orleans, under the name of "Kamna-Fuga," as an antipyretic, and is claimed to have some advantages over acetanilid by itself.

313. PULVIS ALOES ET CANELLÆ. *N. F.*

Powder of Aloes and Canella.

Hiera Picra.

Purified Aloes (U. S. P.), in fine powder	80 Gm.
Canella, in fine powder	20 Gm.

Mix them intimately.

314. PULVIS AMYGDALÆ COMPOSITUS. *N. F.*

Compound Powder of Almond.

Sweet Almond	60 Gm.
Sugar, in fine powder	30 Gm.
Acacia, in fine powder	10 Gm.

Blanch the Sweet Almonds, then dry them thoroughly with a soft cloth, and rub them lightly in a mortar, until they form a mass of a smooth consistence. Mix the Acacia and Sugar, add them to the mass previously prepared, and rub the whole to a coarse powder, which is to be preserved in a lightly covered jar.

Note.—If 820 grains of this preparation be thoroughly triturated with 17 fluidounces of Water, gradually added, and the mixture finally strained, the product will be about 16 fluidounces of *Mistura Amygdalæ* (U. S. P.).

315. PULVIS ANTICATARRHALIS. *N. F.*

Catarrh Powder.

Catarrh Snuff.

Morphine Hydrochlorate	0.41 Gm.
Acacia, in fine powder	25 Gm.
Bismuth Subnitrate	75 Gm.

Mix them intimately by trituration.

316. PULVIS CATECHU COMPOSITUS. *N. F.*

Compound Powder of Catechu.

Catechu, in fine powder	40 Gm.
Kino, in fine powder	20 Gm.
Krameria, in fine powder	20 Gm.
Cinnamon, in fine powder	10 Gm.
Nutmeg, in fine powder	10 Gm.

Mix them intimately, pass the powder through a fine sieve, and afterwards rub it lightly in a mortar. Keep it in a stoppered bottle.

Note.—This preparation is official in the Brit. Pharm.

317. PULVIS CRETÆ AROMATICUS. *N. F.*

Aromatic Powder of Chalk.

Cinnamon	8 Gm.
Saffron	6 Gm.
Nutmeg	6 Gm.
Cloves	3 Gm.
Cardamom	2 Gm.
Prepared Chalk	23 Gm.
Sugar	52 Gm.

Mix the ingredients and reduce them to a fine powder. Pass this through a fine sieve, and afterwards rub it lightly in a mortar. Keep it in a stoppered bottle.

Note.—This preparation is equivalent to the *Pulvis Cretæ Aromaticus* of the Brit. Pharm. This authority adds the following note: "If a product of bright color be desired, the saffron may previously be moistened and triturated with a little water or alcohol, or the fresh and faintly damp mixture may be subjected to considerable pressure in the triturating process."

318. PULVIS CRETÆ AROMATICUS CUM OPIO. *N. F.*

Aromatic Powder of Chalk with Opium.

Aromatic Powder of Chalk (F. 317)	97.5 Gm.
Powdered Opium	2.5 Gm.

Mix them intimately.

Every 40 grains of this preparation contain 1 grain of Powdered Opium.

Note.—This preparation is official in the Brit. Pharm.

319. PULVERES EFFERVESCENTES.

Effervescent Powders.

The Effervescent Powders for which formulas are given in the Formulary are most conveniently and efficiently dispensed in the form of *fine powders*, because in this condition they can be made extemporaneously and with an assurance of their freshness and efficiency. The popular demand, however, seems to be for Granular Effervescent Powders, the preparation of which requires certain modifications of the formulas, important only in so far as they enable the dispenser to granulate the powder in a convenient and expeditious manner.

General Observations and Directions.

Effervescent Powders are composed of the medicinal agent in admixture with an alkaline bicarbonate, an organic acid, and sugar. The proportion of the medicinal agent is dependent upon its dose; that of the alkaline

bicarbonate and of the organic acid is dependent upon their molecular relation to each other; while the proportion of sugar is dependent upon the quantity necessary as a sweetening agent and diluent.

The ingredients for making the *fine pulverulent form* of Effervescent Powders are: The Medicinal Agent, Sodium Bicarbonate, Tartaric Acid, and Sugar, and it is necessary that these be well dried before mixing them.

To make the *granular form* of Effervescent Powders the ingredients need not be dried, unless specially directed, and the ingredients are the same as for the pulverulent form, with the single *exception that one-half the molecule of Tartaric Acid is replaced by one-half a molecule of Crystallized Citric Acid.*

With the view to simplifying the formulas for Effervescent Powders, three new preparations have been embodied in this Formulary, viz.:

Acidum Citricum Saccharatum (Saccharated Citric Acid), Formula No. 5.

Acidum Tartaricum Saccharatum (Saccharated Tartaric Acid), Formula No. 8.

Sodii Bicarbonas Saccharatus (Saccharated Sodium Bicarbonate), Formula No. 341.

The proportion of Sugar in these new Saccharates is so adjusted that when either of the Acid Saccharates is mixed with an equal weight of the Alkaline Saccharate, the acid and alkali are in molecular relation to each other, and when dissolved in Water, will form the Neutral Tartrate and Citrate of Sodium respectively.

With these three Saccharates in stock it becomes possible to make Effervescent Powders quickly with any medicinal agent that may be prescribed, while they simplify the formulas for the Effervescent preparations now in the Formulary, their use being exemplified by the following *General Formulas:*

General Formulas.

FORMULA A. *Fine Powder.*

Medicinal Agent, in fine powder	50 Gm.
Saccharated Sodium Bicarbonate (F. 341)	475 Gm.
Saccharated Tartaric Acid (F. 8)	475 Gm.

Triturate the ingredients, *previously well dried,* until a uniformly mixed powder is obtained.

FORMULA B. *Granular Powder.*

Medicinal Agent, in fine powder	50 Gm.
Saccharated Sodium Bicarbonate (F. 341)	475 Gm.
Saccharated Tartaric Acid (F. 8)	237.5 Gm.
Saccharated Citric Acid (F. 5)	237.5 Gm.

Mix the ingredients in a mortar, transfer them to an evaporating dish, and heat upon a water-bath, kept at 60°–71° C. (140°–160° F.), under constant stirring with a wooden spatula, until dry and uniformly granular.

The Saccharated Citric Acid, being made from crystallized Citric Acid containing one molecule of Water of Crystallization, supplies the moisture necessary to cause the powder, when heated, to cake and adhere together. If the somewhat pasty mass is then stirred with the spatula, small granules are readily formed, and these become firm when completely dried.

Throughout this process the contact of the powder with metals should be carefully avoided.

Effervescent Powders should be preserved in well-stoppered wide-mouthed vials.

Note.—To make these Effervescent Compounds it is not necessary to have the Saccharated Alkali and Saccharated Acids in stock. The quantities of Sodium Bicarbonate, of Tartaric Acid, of Citric Acid, and of Sugar, required for each formula are readily ascertained by simple calculation, according to the following rule

Multiply the number of grammes of the Saccharate prescribed by the figures indicating the percentage of alkali or acid it contains, and divide the sum of this by one hundred. The quotient is the quantity of Alkali or Acid, expressed in grammes, and by deducting this quantity from the total quantity of the Saccharate, the quantity of Sugar necessary is ascertained.

Applying this rule, by way of example, to *General Formula B.*, we have the following result:

(*a*) 475 Gm. of Saccharated Sodium Bicarbonate, containing 75 %, require 356.25 Gm. of Sodium Bicarbonate and 118.75 Gm. of Sugar.

(*b*) 237.5 Gm. of Saccharated Tartaric Acid, containing 67.5 %, require 160.3 Gm. of Tartaric Acid and 77.2 Gm. of Sugar.

(*c*) 237.5 Gm. of Saccharated Citric Acid, containing 62.5 %, require 148.4 Gm. of Citric Acid and 89.1 Gm. of Sugar.

And the formula would then be:

Medicinal Agent	50 Gm.
Sodium Bicarbonate	356.25 Gm.
Tartaric Acid	160.3 Gm.
Citric Acid	148.4 Gm.
Sugar	285.05 Gm.
To make	1000 Gm.

320. PULVIS FERRI ET QUININÆ CITRATIS EFFERVESCENS. *N. F.*

Effervescent Powder of Citrate of Iron and Quinine.

Effervescent Iron and Quinine Citrate.

Soluble Iron and Quinine Citrate (U. S. P.), in very fine powder	10 Gm.
Saccharated Sodium Bicarbonate (F. 341)	495 Gm.
Saccharated Tartaric Acid (F. 8)	495 Gm.

Mix the ingredients, previously well dried, and triturate them until a uniform powder is obtained.

To make

Granular Effervescent Iron and Quinine Citrate,

Substitute Saccharated Citric Acid (F. 5), *not dried, two hundred and forty-seven and one-half* (247.5) *grammes,* for an equal weight of the Saccharated Tartaric Acid, and prepare the granulated compound as directed under General Formula (F. 319, B.).

Ninety (90) *grains* (*or about a heaped teaspoonful*) *of this preparation represent about one* (1) *grain of Iron and Quinine Citrate.*

321. PULVIS FERRI PHOSPHATIS EFFERVESCENS. *N. F.*

Effervescent Powder of Ferric Phosphate.

Effervescent Phosphate of Iron.

Ferric Phosphate (U. S. P.), in very fine powder	24 Gm.
Saccharated Sodium Bicarbonate (F. 341)	488 Gm.
Saccharated Tartaric Acid (F. 8)	488 Gm.

Mix the ingredients, *previously well dried,* and triturate them until a uniform powder is obtained.

To make

Granular Effervescent Ferric Phosphate,

Substitute Saccharated Citric Acid (F. 5), *not dried, two hundred and forty-four* (244) *grammes,* for an equal weight of the Saccharated Tartaric Acid, and prepare the granulated compound as directed under the General Formula (F. 319, B.).

Ninety (90) *grains* (*or about a heaped teaspoonful*) *of this preparation represent about two* (2) *grains of Ferric Phosphate.*

322. PULVIS HYDRARGYRI CHLORIDI MITIS ET JALAPÆ. *N. F.*

Powder of Mild Mercurous Chloride and Jalap.

Calomel and Jalap.

Mild Mercurous Chloride	34 Gm.
Jalap, in fine powder	66 Gm.

Mix them intimately.

Note.—When "Calomel and Jalap" is prescribed for an adult, without any specification of quantities, it is recommended that about 30 grains be dispensed as one dose.

323. PULVIS IODOFORMI COMPOSITUS. *N. F.*

Compound Powder of Iodoform.

Iodoform and Naphtalin.

Iodoform, in fine powder	**20 Gm.**
Boric Acid, in fine powder	**30 Gm.**
Naphtalin	**50 Gm.**
Oil of Bergamot	**2.5 Cc.**

Triturate the Naphtalin with the Oil of Bergamot, then mix it with the Iodoform and Boric Acid, and triturate until a homogeneous powder is produced.

Note.—This powder is used in many cases where a *diluted* preparation of Iodoform, for external purposes, is desired. The odor of the Iodoform is masked both by the Oil of Bergamot and by the Naphtalin.

324. PULVIS KINO COMPOSITUS. *N. F.*

Compound Powder of Kino.

Kino, in fine powder	**75 Gm.**
Powdered Opium	**5 Gm.**
Cinnamon, in fine powder	**20 Gm.**

Mix them intimately, pass the mixed powder through a moderately fine sieve, and afterwards rub it lightly in a mortar. Keep it in a stoppered bottle.

Every 20 grains of this preparation contain 1 grain of Powdered Opium.

Note.—This preparation is official in the Brit. Pharm.

325. PULVIS MYRICÆ COMPOSITUS. *N. F.*

Compound Powder of Bayberry.

Composition Powder.

Bayberry, bark of the root	**60 Gm.**
Ginger	**30 Gm.**
Capsicum	**5 Gm.**
Cloves	**5 Gm.**

Reduce the substances to a moderately fine powder.

326. PULVIS PANCREATICUS COMPOSITUS. *N. F.*

Compound Pancreatic Powder.

Peptonizing Powder.

Pancreatin (U. S. P.)	**20 Gm.**
Sodium Bicarbonate	**80 Gm.**

Mix them by trituration.

Note.—If Pancreatin of proper strength is not available, any other commercial preparation of the pancreas, as, for instance, the extract, may be used in place of it, provided it attains the required standard. See page 1006.

Twenty-five (25) grains of this powder are sufficient to peptonize 1 pint of fresh cow's milk, by proceeding in the following manner:

Add the Compound Pancreatic Powder to 4 fluidounces of tepid Water, contained in a suitable flask, and afterwards add 1 pint of fresh cow's Milk, previously heated to 38° C. (100.4° F.). Maintain the mixture at this temperature during thirty minutes, then transfer the flask to a cold place.

Milk thus peptonized should not be used when it has been kept over twenty-four hours, or when it has developed a bitter taste.

327. PULVIS PEPSINI COMPOSITUS. *N. F.*

Compound Powder of Pepsin.

Pulvis Digestivus.

Saccharated Pepsin (U. S. P.)	**15 Gm.**
Pancreatin (U. S. P.)	**15 Gm.**
Diastase	**1 Gm.**
Lactic Acid (U. S. P.)	**1 Cc.**
Hydrochloric Acid (U. S. P.)	**2 Cc.**
Sugar of Milk	**66 Gm.**

Add the Acids gradually to the Sugar of Milk, and triturate until they are thoroughly mixed. Mix the Pepsin, Pancreatin, and Diastase, and then incorporate this mixture, by trituration, with the Sugar of Milk. Finally, rub the mixture through a hair-sieve, and preserve the powder in bottles.

Note.—The best commercial variety of Diastase, capable of converting the largest comparative amount of starch into dextrin and glucose, should be used for this preparation.

328. PULVIS POTASSII BROMIDI EFFERVESCENS. *N. F.*

Effervescent Powder of Potassium Bromide.

Effervescent Potassium Bromide.

Potassium Bromide, in very fine powder	**110 Gm.**
Saccharated Sodium Bicarbonate (F. 341)	**445 Gm.**
Saccharated Tartaric Acid (F. 8)	**445 Gm.**

Mix the ingredients, *previously well dried*, and triturate them until a uniform powder is obtained.

To make

Granular Effervescent Potassium Bromide,

Substitute Saccharated Citric Acid (F. 5), *not dried, two hundred and twenty-two and one-half* (222.5) *grammes*, for an equal weight of the Saccharated Tartaric Acid, and prepare the granulated compound as directed under the General Formula (F. 319, B.).

Ninety (90) *grains* (*or about a heaped teaspoonful*) *of this preparation represent about ten* (10) *grains of Potassium Bromide.*

329. PULVIS POTASSII BROMIDI EFFERVESCENS CUM CAFFEINA. *N. F.*

Effervescent Powder of Potassium Bromide with Caffeine.

Effervescent Potassium Bromide with Caffeine.

Potassium Bromide, in very fine powder	**110 Gm.**
Caffeine, in very fine powder	**11 Gm.**
Saccharated Sodium Bicarbonate (F. 341)	**440 Gm.**
Saccharated Tartaric Acid (F. 8)	**440 Gm.**

Mix the ingredients, *previously well dried*, and triturate them until a uniform powder is obtained.

To make

Granular Effervescent Potassium Bromide with Caffeine,

Substitute Saccharated Citric Acid (F. 5), *not dried, two hundred and twenty* (220) *grammes*, for an equal weight of the Saccharated Tartaric Acid, and prepare the granulated compound as directed under the General Formula (F. 319, B.).

Ninety (90) *grains* (*or about a heaped teaspoonful*) *of this preparation represent about ten* (10) *grains of Potassium Bromide and one* (1) *grain of Caffeine.*

330. PULVIS RHEI ET MAGNESIÆ ANISATUS. *N. F.*

Anisated Powder of Rhubarb and Magnesia.

Compound Anise Powder.

Rhubarb, in fine powder	**35 Gm.**
Heavy Magnesia, calcined	**65 Gm.**
Oil of Anise	**8 Cc.**
Alcohol	**10 Cc.**

Mix the powders, add the Oil of Anise previously dissolved in the Alcohol, and triturate until a uniform mixture results.

331. PULVIS SALIS CAROLINI FACTITII EFFERVESCENS. *N. F.*

Effervescent Powder of Artificial Carlsbad Salt.

Effervescent Artificial Carlsbad Salt.

Artificial Carlsbad Salt (F. 336), in form of dry powder	**180 Gm.**
Saccharated Sodium Bicarbonate (F. 341)	**410 Gm.**
Saccharated Tartaric Acid (F. 8)	**410 Gm.**

Mix the ingredients, *previously well dried*, and triturate them until a uniform powder is obtained.

To make

Granular Effervescent Artificial Carlsbad Salt,

Substitute Saccharated Citric Acid (F. 5), *not dried, two hundred and five* (205) *grammes*, for an equal weight of the Saccharated Tartaric Acid, and prepare the granulated compound as directed under the General Formula (F. 319, B.).

A solution of about eighty-seven (87) *grains of this preparation, in six* (6) *fluidounces of Water, represents an equal volume of Carlsbad Water (Sprudel), in its essential constituents.*

332. PULVIS SALIS KISSINGENSIS FACTITII EFFERVESCENS. *N. F.*

Effervescent Powder of Artificial Kissingen Salt.

Effervescent Artificial Kissingen Salt.

Artificial Kissingen Salt (F. 337)	280 Gm.
Saccharated Sodium Bicarbonate (F. 341)	360 Gm.
Saccharated Tartaric Acid (F. 8)	360 Gm.

Mix the ingredients, *previously well dried*, and triturate them until a uniform powder is obtained.

To make

Granular Effervescent Artificial Kissingen Salt,

Substitute Saccharated Citric Acid (F. 5), *not dried, one hundred and eighty* (180) *grammes*, for an equal weight of the Saccharated Tartaric Acid, and prepare the granulated compound as directed under the General Formula (F. 319, B.).

A solution of about eighty (80) *grains of this preparation, in six* (6) *fluidounces of Water, represents an equal volume of Kissingen Water (Rakoczi Springs) in its essential constituents.*

333. PULVIS SALIS VICHYANI FACTITII EFFERVESCENS. *N. F.*

Effervescent Powder of Artificial Vichy Salt.

Effervescent Artificial Vichy Salt.

Artificial Vichy Salt (F. 338)	240 Gm.
Saccharated Sodium Bicarbonate (F. 341)	380 Gm.
Saccharated Tartaric Acid (F. 8)	380 Gm.

Mix the ingredients, *previously well dried*, and triturate them until a uniform powder is obtained.

To make

Granular Effervescent Artificial Vichy Salt,

Substitute Saccharated Citric Acid (F. 5), *not dried, one hundred and ninety* (190) *grammes*, for an equal weight of the Saccharated Tartaric Acid, and prepare the granulated compound as directed under the General Formula (F. 319, B.).

A solution of about fifty-seven (57) *grains of this preparation, in six* (6) *fluidounces of Water, represents an equal volume of Vichy Water (Grande Grille Spring), in its essential constituents.*

334. PULVIS SALIS VICHYANI FACTITII EFFERVESCENS CUM LITHIO. *N. F.*

Effervescent Powder of Artificial Vichy Salt with Lithium.

Effervescent Artificial Vichy Salt with Lithium.

Artificial Vichy Salt (F. 338)	156 Gm.
Lithium Citrate, in very fine powder	56 Gm.
Saccharated Sodium Bicarbonate (F. 341)	394 Gm.
Saccharated Tartaric Acid (F. 8)	394 Gm.

Mix the ingredients, *previously well dried*, and triturate them until a uniform powder is obtained.

To make

Granular Effervescent Artificial Vichy Salt with Lithium,

Substitute Saccharated Citric Acid (F. 5), *not dried, one hundred and ninety-seven* (197) *grammes*, for an equal weight of the Saccharated Tartaric Acid, and prepare the granulated compound as directed under the General Formula (F. 319, B.).

Ninety (90) *grains (or about a heaped teaspoonful) of this preparation represent fourteen* (14) *grains of Artificial Vichy Salt and five* (5) *grains of Lithium Citrate.*

335. PULVIS TALCI SALICYLICUS. *N. F.*

Salicylated Powder of Talcum.

Salicylic Acid	30 Gm.
Boric Acid, in fine powder	100 Gm.
Talcum, in fine powder	870 Gm.

Mix them intimately.

336. SAL CAROLINUM FACTITIUM. *N. F.*

Artificial Carlsbad Salt.

I. *In a dry, amorphous form* (Germ. Pharm.).

Potassium Sulphate	20 Gm.
Sodium Chloride	180 Gm.
Sodium Bicarbonate	360 Gm.
Sodium Sulphate, dried	440 Gm.

Triturate the ingredients, previously well dried, to a fine, uniform powder.

Note.—The dried Sodium Sulphate is prepared by slowly drying the crystalline salt until it has lost one-half of its weight.

II. *In a crystalline form.*

Potassium Sulphate	20 Gm.
Sodium Chloride	180 Gm.
Sodium Carbonate, in clear crystals	610 Gm.
Sodium Sulphate, crystallized	880 Gm.
Distilled Water	500 Gm.

Dissolve the Potassium Sulphate and Sodium Chloride in the Distilled Water, and add this solution to the other two salts, previously melted in a tared capsule and at a gentle heat in their own water of crystallization. Evaporate the mixture to about *eighteen hundred* (1800) *grammes*, set it aside in a cool place, and stir frequently, so as to prevent the formation of large crystals, taking care, however, that none of the salt separates in a pulverulent form. Distribute any remaining water of crystallization uniformly over the crystals, and dry the whole mixture sufficiently by exposure to air, so that it will retain its crystalline character.

A solution of about 16 grains of the dry, or about 27 grains of the crystalline salt, in 6 fluidounces of water, represents an equal volume of Carlsbad Water (Sprudel) in its essential constituents.

Note.—The salts employed in the preparation of the crystalline form must have been purified by recrystallization.

337. SAL KISSINGENSE FACTITIUM. *N. F.*

Artificial Kissingen Salt.

Potassium Chloride	17 Gm.
Sodium Chloride	357 Gm.
Magnesium Sulphate, anhydrous	59 Gm.
Sodium Bicarbonate	107 Gm.

Triturate the ingredients, previously well dried, to a fine, uniform powder.

A solution of about 24 grains of this preparation, in 6 fluidounces of water, represents an equal volume of Kissingen Water (Rakoczi Spring) in its essential constituents.

338. SAL VICHYANUM FACTITIUM. *N. F.*

Artificial Vichy Salt.

Sodium Bicarbonate	846 Gm.
Potassium Carbonate	38.5 Gm.
Magnesium Sulphate, anhydrous	38.5 Gm.
Sodium Chloride	77 Gm.

Triturate the ingredients, previously well dried, to a fine, uniform powder.

A solution of about 14 grains of this preparation, in 6 fluidounces of water, represents an equal volume of Vichy Water (Grande Grille Spring) in its essential constituents.

339. SODA CUM CALCE. *N. F.*

Soda with Lime.

London Paste.

Soda,	
Lime, each	equal parts.

Reduce them to powder in a clean iron mortar, previously warmed, and mix them intimately. Keep the powder in small, well-stoppered vials.

340. SODII BORO-BENZOAS. *N. F.*

Sodium Boro-Benzoate.

Sodium Borate, in fine powder	3 parts.
Sodium Benzoate	4 parts.

Mix them intimately.

341. SODII BICARBONAS SACCHARATUS. *N. F.*

Saccharated Sodium Bicarbonate.

Sodium Bicarbonate (U. S. P.), in very fine powder	750 Gm.
Sugar, in very fine powder	250 Gm.

Triturate the powders together until intimately mixed, and preserve the product in well-stoppered bottles.

Note.—This Saccharate, when dissolved in water with an equal weight of Saccharated Citric Acid (F. 5), or of Saccharated Tartaric Acid (F. 8), will form a neutral solution, and it is introduced into the Formulary for the convenient preparation of Effervescent Powders (F. 319).

This Saccharate contains 75 % of Sodium Bicarbonate.

342. SPECIES EMOLLIENTES. *N. F.*

Emollient Species.

Emollient Cataplasm. (Germ. Pharm.)

Althæa Leaves,	
Mallow Leaves,	
Melilot Tops,	
Matricaria,	
Flaxseed, of each	equal parts.

Reduce them to a coarse powder, and mix it uniformly.

343. SPECIES LAXANTES. *N. F.*

Laxative Species.

St. Germain Tea. (Germ. Pharm.)

Senna, cut	16 parts.
Elder Flowers	10 parts.
Fennel, bruised	5 parts.
Anise, bruised	5 parts.
Potassium Bitartrate, in fine powder	4 parts.

Moisten the Senna with a small quantity of water; then sprinkle over it, as uniformly as possible, the Potassium Bitartrate. When it has become dry, mix it lightly and uniformly with the other ingredients.

344. SPECIES PECTORALES. *N. F.*

Pectoral Species.

Species ad Infusum Pectorale. Breast Tea. (Germ. Pharm.)

Althæa, peeled	8 parts.
Coltsfoot Leaves	4 parts.
Glycyrrhiza, Russian, peeled	3 parts.
Anise	2 parts.
Mullein Flowers	2 parts.
Orris Root	1 part.

Cut, bruise, and mix them.

Note.—Infusum pectorale (Pectoral Infusion, or Infusion of Pectoral Species) is made by infusing 1 troyounce of the above preparation in the usual manner, so as to obtain 10 fluidounces of strained product.

345. SPIRITUS ACIDI FORMICI. *N. F.*

Spirit of Formic Acid.

Spiritus Formicarum (Germ. Pharm.). *Spirit of Ants.*

Formic Acid	35 Cc.
Distilled Water	225 Cc.
Alcohol, a sufficient quantity	
To make	1000 Cc.

Mix the Formic Acid with the Distilled Water, and add enough Alcohol to make *one thousand* (1000) *cubic centimeters.*

Note.—Formic Acid is required by the Germ. Pharm. to have a specific gravity of 1.060 to 1.063.

346. SPIRITUS AROMATICUS. *N. F.*

Aromatic Spirit.

Compound Spirit of Orange (U. S. P.)	65 Cc.
Deodorized Alcohol	935 Cc.

Mix them. Preserve the product, if it is to be kept in stock, in completely filled and well-stoppered vials or bottles, and stored in a cool and dark place.

Aromatic Spirit may also be prepared in the following manner:

Sweet Orange Peel, fresh, and deprived of the white, inner portion	675 Gm.
Lemon Peel, fresh	85 Gm.
Coriander, bruised	85 Gm.
Oil of Star-anise	1.5 Cc.
Deodorized Alcohol, a sufficient quantity	
To make	5000 Cc.

Macerate the solids during four days with *forty-five hundred* (4500) *cubic centimeters* of Deodorized Alcohol; then add the Oil of Star-anise, filter, and pass enough Deodorized Alcohol through the filter to make the product measure *five thousand* (5000) *cubic centimeters.*

Note.—When good, fresh essential oils cannot be readily obtained for preparing the Compound Spirit of Orange, the second formula may be used. But the product obtained by it should not be employed in mixtures containing *iron*, as the latter would cause a darkening of the mixture.

347. SPIRITUS CARDAMOMI COMPOSITUS. *N. F.*

Compound Spirit of Cardamom.

Oil of Cardamom	2 Cc.
Oil of Caraway	0.75 Cc.
Oil of Cinnamon, Cassia	0.50 Cc.
Alcohol	500 Cc.
Glycerin	65 Cc.
Water, a sufficient quantity	
To make	1000 Cc.

Dissolve the Oils in the Alcohol, add the Glycerin, and, lastly, enough Water to make *one thousand* (1000) *cubic centimeters.*

Note.—This preparation is intended as a flavoring ingredient, being equivalent to the official *Tinctura Cardamomi Composita*, without the coloring matter.

348. SPIRITUS CURASSAO. *N. F.*

Spirit of Curaçao.

Oil of Curaçao Orange	165 Cc.
Oil of Fennel	3 Cc.
Oil of Bitter Almond	0.75 Cc.
Deodorized Alcohol	832 Cc.

Mix the Oils with the Deodorized Alcohol, and keep the Spirit in completely filled and well-corked bottles, and stored in a cool and dark place.

349. SPIRITUS ODORATUS. *N. F.*

(U. S. P., 1880.)

Perfumed Spirit.

Cologne Water.

Oil of Bergamot	15 Cc.
Oil of Lemon	8 Cc.

Oil of Rosemary	7 Cc.
Oil of Lavender Flowers	4 Cc.
Oil of Orange Flowers	4 Cc.
Acetic Ether	2 Cc.
Water	120 Cc.
Alcohol	840 Cc.

Dissolve the Oils and the Acetic Ether in the Alcohol, and add the Water. Set the Mixture aside, in a well-closed bottle, for eight days, then filter through paper, in a well-covered funnel.

350. SPIRITUS OLEI VOLATILIS. *N. F.*

Spirit of a Volatile Oil.

Any Spirit or alcoholic Solution of a Volatile Oil, for which no formula is given by the U. S. P. or by this Formulary, should be prepared in accordance with the following general formula:

Any Volatile Oil	65 Cc.
Deodorized Alcohol	935 Cc.

Dissolve the Volatile Oil in the Deodorized Alcohol.

Note.—The strength of the Spirit thus prepared is approximately 5 per cent. by weight, provided the specific gravity of the Oil is in the neighborhood of 0.900.

351. SPIRITUS OPHTHALMICUS. *N. F.*

Ophthalmic Spirit.

Alcoholic Eye-Wash.

Oil of Lavender	2 Cc.
Oil of Rosemary	6 Cc.
Alcohol	92 Cc.

Mix them by agitation, and, if necessary, filter the liquid through paper.

352. SPIRITUS SAPONATUS. *N. F.*

Spirit of Soap.

Castile Soap, in shavings	175 Gm.
Alcohol	600 Cc.
Water, a sufficient quantity	
To make	1000 Cc.

Introduce the Soap into a bottle, add the Alcohol and *two hundred* (200) *cubic centimeters* of Water, cork the bottle, and immerse it in hot Water, frequently shaking. When the Soap is dissolved, allow the bottle and contents to become cold, then add enough Water to make *one thousand* (1000) *cubic centimeters*, and filter.

Note.—The *Spiritus Saponatus* of the Germ. Pharm. is prepared by saponifying Olive Oil with Potassa, and then adding Alcohol and Water.

If time permits, the Spirit ought to be set aside, in a moderately cold place, for about twelve hours, before it is filtered.

353. SPIRITUS SINAPIS. *N. F.*

Spirit of Mustard.

Volatile Oil of Mustard	2 Gm.
Alcohol	100 Gm.

Mix them.

354. SPONGIA COMPRESSA. *N. F.*

Compressed Sponge.

Sponge Tent.

Sponge	a sufficient quantity.
Mucilage of Acacia (U. S. P.)	1 volume.
Water	9 volumes.

Mix a sufficient quantity of Mucilage of Acacia and of Water, in the proportion of *one* (1) *volume* of the former to *nine* (9) *volumes* of the latter, and immerse in the liquid the Sponge, previously freed from sand and other obvious impurities, and cut into suitable pieces. When the Sponge has been thoroughly impregnated, firmly wrap twine around it so as to bring it to the desired shape, and then dry it.

Note.—Sponge thus prepared is best preserved with the twine wrapped around it. If the twine is removed, special care must be taken to protect the Sponge against damp air.

355. SPONGIA DECOLORATA. *N. F.*

Decolorized Sponge.

Bleached Sponge.

Sponge,	
Potassium Permanganate,	
Sodium Hyposulphite,	
Hydrochloric Acid,	
Water, each	a sufficient quantity.

Free the Sponge from sand and any other obvious impurities or damaged portions by beating, washing, and trimming, then soak it for about fifteen minutes in a sufficient quantity of Solution of Potassium Permanganate, containing *fifteen* (15) *grammes* to the *liter*, wringing the Sponge out occasionally and replacing it in the liquid. Then remove it and wash it with Water, until the latter runs off colorless. Wring out the Water, and then place the Sponge in a Solution of Sodium Hyposulphite, containing *sixty* (60) *grammes* to the *liter*. Next add, for every *liter* of the last-named solution used, *sixty* (60) *cubic centimeters* of Hydrochloric Acid diluted with *two hundred and fifty* (250) *cubic centimeters* of Water. Macerate the Sponge in the liquid for about fifteen minutes, expressing it frequently and replacing it in the liquid. Then remove it, wash it thoroughly with Water, and dry it. In the case of large and dark-colored sponges, this treatment may be repeated until the color has been removed as far as possible.

Note.—If it is desired to keep the Sponge soft and to prevent it from shrinking when dry, it may be dipped, after having been finally washed, into a mixture of 1 volume of Glycerin and 5 Volumes of Water, after which it is to be wrung out and allowed to dry.

356. SUCCUS LIMONIS CUM PEPSINO. *N. F.*

Lime Juice and Pepsin.

Pepsin (U. S. P.)	35 Gm.
Water	175 Cc.
Glycerin	175 Cc.
Alcohol	90 Cc.
Purified Talcum (F. 395)	15 Gm.
Lime Juice, a sufficient quantity	
To make	1000 Cc.

Dissolve the Pepsin in the Water, mixed with about *five hundred* (500) *cubic centimeters* of Lime Juice. Then add the Glycerin and Alcohol, and, lastly, enough Lime Juice to make *one thousand* (1000) *cubic centimeters*. Incorporate the Purified Talcum with the liquid, let it stand a few days in a cold place, if convenient, occasionally agitating, then filter it through a wetted filter, and finally pass enough Lime Juice through the filter to restore the original volume.

Each fluidrachm represents 2 grains of Pepsin (U. S. P.).

357. SYRUPUS ACTÆÆ COMPOSITUS. *N. F.*

Compound Syrup of Actæa.

Compound Syrup of Cimicifuga (or *Black Cohosh*).

Fluid Extract of Cimicifuga (U. S. P.)	40 Cc.
Fluid Extract of Glycyrrhiza (U. S. P.)	20 Cc.
Fluid Extract of Senega (U. S. P.)	20 Cc.
Fluid Extract of Ipecac (U. S. P.)	10 Cc.
Wild Cherry, in moderately fine powder	40 Gm.
Purified Talcum (F. 395)	15 Gm.
Sugar	650 Gm.
Water, a sufficient quantity	
To make	1000 Cc.

Mix the Wild Cherry with *three hundred and fifty* (350) *cubic centimeters* of Water, and allow it to macerate during one hour. Then add to it the Fluid Extracts and the Talcum, and stir or agitate the mixture frequently and thoroughly during about fifteen minutes. Transfer it to a wetted filter, and, when the liquid ceases to drop from the

funnel, wash the contents of the filter with Water to obtain *five hundred* (500) *cubic centimeters* of filtrate. In this dissolve the Sugar by agitation, and add enough Water, previously passed through the filter, to make *one thousand* (1000) *cubic centimeters.*

358. SYRUPUS ASARI COMPOSITUS. *N. F.*

Compound Syrup of Asarum.

Compound Syrup of Canada Snake-Root.

Asarum, root, in moderately coarse (No. 40) powder	60	Gm.
Alcohol	185	Cc.
Cochineal, in fine powder	1.5	Gm.
Potassium Carbonate	2.5	Gm.
Wine of Ipecac (U. S. P.)	30	Cc.
Sugar	700	Gm.
Water, a sufficient quantity		
To make	1000	Cc.

Mix the Asarum intimately with the Cochineal and Potassium Carbonate, previously triturated together. Moisten the powder with a sufficient quantity of a menstruum prepared by mixing the Alcohol with *three hundred and fifty* (350) *cubic centimeters* of Water, and allow it to macerate, in a covered vessel, for twenty-four hours. Then transfer it to a small percolator, and pour on the remainder of the menstruum. Allow the percolation to proceed slowly, and then follow up the menstruum by Water, until *five hundred* (500) *cubic centimeters* of percolate are obtained. To this add the Wine of Ipecac, and afterwards the Sugar, and dissolve the latter by agitation. Finally, add enough Water, previously passed through the percolator, to make *one thousand* (1000) *cubic centimeters.*

Each fluidrachm represents about 3½ grains of Asarum.

359. SYRUPUS CALCII CHLORHYDROPHOSPHATIS. *N. F.*

Syrup of Calcium Chlorhydrophosphate.

Syrup of Chlorhydrophosphate of Lime.

Precipitated Calcium Phosphate	17.5	Gm.
Spirit of Lemon (U. S. P.)	20	Cc.
Hydrochloric Acid (U. S. P.), Water, Syrup (U. S. P.), of each, a sufficient quantity		
To make	1000	Cc.

Triturate the Precipitated Calcium Phosphate with *thirty* (30) *cubic centimeters* of Water, and dissolve it with the aid of Hydrochloric Acid, avoiding an excess. Then add the Spirit of Lemon, filter the liquid, and wash the filter with a mixture of *thirty* (30) *cubic centimeters*, each, of Water and of Syrup. Lastly, add enough Syrup to the filtrate, to make *one thousand* (1000) *cubic centimeters.*

Each fluidrachm contains 1 grain of Calcium Phosphate.

360. SYRUPUS CALCII ET SODII HYPOPHOSPHITUM. *N. F.*

Syrup of Calcium and Sodium Hypophosphites.

Syrup of Hypophosphite of Lime and Soda.

Calcium Hypophosphite	35	Gm.
Sodium Hypophosphite	35	Gm.
Citric Acid	1.5	Gm.
Sugar	775	Gm.
Water, a sufficient quantity		
To make	1000	Cc.

Dissolve the two Hypophosphites and the Citric Acid in *five hundred* (500) *cubic centimeters* of Water, filter the solution, add the Sugar to the filtrate, and pass enough Water through the filter to make the product, after the Sugar has been dissolved by agitation, measure *one thousand* (1000) *cubic centimeters.*

Each fluidrachm contains 2 grains, each, of Calcium Hypophosphite and Sodium Hypophosphite.

361. SYRUPUS CALCII HYPOPHOSPHITIS. *N. F.*

Syrup of Calcium Hypophosphite.

Syrup of Hypophosphite of Lime.

Calcium Hypophosphite	35	Gm.
Citric Acid	1.5	Gm.
Sugar	775	Gm.
Water, a sufficient quantity		
To make	1000	Cc.

Dissolve the Calcium Hypophosphite and the Citric Acid in *five hundred* (500) *cubic centimeters* of Water, filter the solution, add the Sugar to the filtrate, and pass enough Water through the filter to make the product, after the Sugar has been dissolved by agitation, measure *one thousand* (1000) *cubic centimeters.*

Each fluidrachm contains 2 grains of Calcium Hypophosphite.

362. SYRUPUS CALCII IODIDI. *N. F.*

Syrup of Calcium Iodide.

Iodine	76	Gm.
Iron Wire, fine, bright, and finely cut	28	Gm.
Precipitated Calcium Carbonate	34	Gm.
Sugar	700	Gm.
Distilled Water, Syrup (U. S. P.), of each, a sufficient quantity		
To make	1000	Cc.

Mix the Iron Wire with *fifty-seven* (57) *grammes* of the Iodine and *one hundred and eighty-five* (185) *cubic centimeters* of Distilled Water, and apply a gentle heat, until the Iodine is combined, and the liquid has acquired a greenish color. Filter the liquid through a small filter into a flask containing the remainder of the Iodine, wash the filter with *sixty* (60) *cubic centimeters* of Distilled Water, and heat the solution gently, taking care that no iodine is lost by evaporation. Heat *two hundred and fifty* (250) *cubic centimeters* of Distilled Water in a capacious capsule to boiling, and add to it small alternate portions, first of the Precipitated Calcium Carbonate, and then of the Solution of Ferrous Iodide, in small portions at a time, stirring briskly and waiting until the violence of the reaction moderates before adding a fresh portion. From time to time, add a little Distilled Water, to replace that lost by evaporation. When all the Iron solution has been added, continue heating the mixture until it is quietly boiling, then filter it through a wetted filter, and wash the latter with enough Distilled Water to make the product, when cold, measure *five hundred* (500) *cubic centimeters.* In this dissolve the Sugar by agitation, then make up the volume with Syrup to *one thousand* (1000) *cubic centimeters*, and strain, if necessary.

Each fluidrachm contains about 5 grains of Calcium Iodide.

363. SYRUPUS CALCII LACTOPHOSPHATIS CUM FERRO. *N. F.*

Syrup of Calcium Lactophosphate with Iron.

Syrup of Lactophosphate of Lime with Iron.

Ferrous Lactate	8.5	Gm.
Potassium Citrate	8.5	Gm.
Water	60	Cc.
Syrup of Calcium Lactophosphate (U. S. P.), a sufficient quantity		
To make	1000	Cc.

Dissolve the Ferrous Lactate and Potassium Citrate in the Water with the aid of heat, and add enough Syrup of Calcium Lactophosphate to make *one thousand* (1000) *cubic centimeters.*

Each fluidrachm contains ½ grain of Ferrous Lactate and about ¼ grain of Calcium Lactate (or about ⅝ grain of so-called Calcium Lactophosphate).

364. SYRUPUS CHONDRI COMPOSITUS. *N. F.*

Compound Syrup of Chondrus.

Compound Syrup of Irish Moss.

Irish Moss	1 Gm.
Fluid Extract of Ipecac (U. S. P.)	1 Cc.
Fluid Extract of Squill (U. S. P.)	16 Cc.
Fluid Extract of Senega (U. S. P.)	16 Cc.
Camphorated Tincture of Opium (U. S. P.)	28 Cc.
Purified Talcum (F. 395)	15 Gm.
Sugar	650 Gm.
Water, a sufficient quantity	
To make	1000 Cc.

Macerate the Irish Moss in *sixty* (60) *cubic centimeters* of Water until it is softened, then heat it on a boiling water-bath for fifteen minutes, strain it through flannel, without pressure, and wash the flannel and contents with *sixty* (60) *cubic centimeters* of hot Water. Mix the Fluid Extracts and Tincture with the Purified Talcum and *three hundred and twenty-five* (325) *cubic centimeters* of Water, shake the mixture frequently and thoroughly during half an hour, and then filter it through a wetted filter, returning the first portions of the filtrate until it runs through clear. Mix the mucilage of Irish Moss with the filtrate, then add the Sugar, and pass enough Water through the filter to make the product, after the Sugar has been dissolved by agitation, measure *one thousand* (1000) *cubic centimeters*.

365. SYRUPUS CINNAMOMI. *N. F.*

Syrup of Cinnamon.

Cinnamon (Cassia), in moderately coarse powder	100 Gm.
Alcohol	50 Cc.
Sugar	700 Gm.
Cinnamon Water (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Mix the Alcohol with *four hundred and fifty* (450) *cubic centimeters* of Cinnamon Water, moisten the Cinnamon with a sufficient quantity of this menstruum, and allow it to macerate for about two hours. Then transfer it to a small percolator, and percolate, in the usual manner, using first the remainder of the menstruum above directed, and afterwards, Cinnamon Water. Collect the first *five hundred* (500) *cubic centimeters* of the percolate separately, and dissolve in it the Sugar. Then collect an additional quantity of percolate and add it to the Syrup, so as to make *one thousand* (1000) *cubic centimeters*.

366. SYRUPUS CODEINÆ. *N. F.*

Syrup of Codeine.

Codeine Sulphate	1 Gm.
Syrup (U. S. P.)	100 Cc.

Reduce the Codeine Sulphate to a fine powder and dissolve it in the Syrup previously warmed.

A fluidrachm of this preparation contains about one-half (½) grain of Codeine Sulphate.

Note.—The *Syrupus Codeini* of the French Pharmacopœia is a weaker preparation, containing only about ⅛ grain of Codeine (alkaloid) in a fluidrachm.

367. SYRUPUS COFFEÆ. *N. F.*

Syrup of Coffee.

Coffee, roasted	250 Gm.
Sugar	750 Gm.
Water	a sufficient quantity.

Introduce the Coffee, reduced to a moderately coarse powder, into a suitable vessel; pour upon it *five hundred* (500) *cubic centimeters* of boiling Water, then cover it well, and boil for five minutes. Allow it to become cold, keeping the vessel well covered; strain off the liquid and pass enough Water through the strainer to make the strained liquid, when cold, measure *five hundred* (500) *cubic centimeters*. In this dissolve the Sugar, by agitation, without heat, and strain through muslin.

368. SYRUPUS ERIODICTYI AROMATICUS. *N. F.*

Aromatic Syrup of Eriodictyon.

Aromatic Syrup of Yerba Santa. Syrupus Corrigens.

Fluid Extract of Eriodictyon (U. S. P.)	32 Cc.
Solution of Potassa (U. S. P.)	25 Cc.
Compound Tincture of Cardamom (U. S. P.)	65 Cc.
Oil of Sassafras	0.5 Cc.
Oil of Lemon	0.5 Cc.
Oil of Cloves	1 Cc.
Alcohol	32 Cc.
Sugar	800 Gm.
Water, a sufficient quantity	
To make	1000 Cc.

Mix the Fluid Extract of Eriodictyon and Solution of Potassa, then add *one hundred* (100) *cubic centimeters* of Water previously mixed with the Compound Tincture of Cardamom, and afterwards add the Oils dissolved in the Alcohol. Shake the mixture thoroughly, then filter it, and pour enough Water through the filter to obtain *three hundred and seventy-five* (375) *cubic centimeters* of filtrate. Pour this upon the sugar contained in a bottle, and dissolve it by placing the bottle in hot water, frequently agitating. Lastly, cool the product and add enough Water, passed through the filter previously used, to make *one thousand* (1000) *cubic centimeters*.

369. SYRUPUS FERRI ARSENATIS. *N. F.*

Syrup of Arsenate of Iron.

Sodium Arsenate (U. S. P.), dried to a constant weight at a heat not exceeding 149° C. (300° F.)	0.40 Gm.
Ferric Citrate (U. S. P.)	0.35 Gm.
Water	30 Cc.
Syrup (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Dissolve the Sodium Arsenate and Ferric Citrate in the Water, contained in a test-tube, by the aid of heat. Then mix the solution with enough Syrup to make *one thousand* (1000) *cubic centimeters*.

Each fluidrachm contains about $\frac{1}{60}$ grain of Ferric Arsenate.

370. SYRUPUS FERRI BROMIDI. *N. F.*

(U. S. P., 1880.)

Syrup of Bromide of Iron.

A syrupy liquid containing 10 *per cent. of Ferrous Bromide* ($FeBr_2$, 215.4).

Iron, in the form of fine wire, and cut into small pieces	30 Gm.
Bromine	75 Gm.
Sugar, in coarse powder	600 Gm.
Distilled Water, a sufficient quantity	
To make	1000 Gm.

Introduce the Iron into a flask of thin glass of suitable capacity, add to it *two hundred* (200) *grammes* of Distilled Water and afterwards the Bromine. Shake the mixture occasionally, until the reaction ceases and the solution has acquired a green color and has lost the odor of Bromine. Place the Sugar in a porcelain capsule and filter the Solution of Ferrous Bromide into the Sugar. Rinse the flask and Iron wire with *ninety* (90) *grammes* of Distilled Water and pass the washings through the filter into the Sugar. Stir the mixture with a porcelain or wooden spatula, heat it to the boiling point on a sand-

bath, and, having strained the Syrup through linen into a tared bottle, add enough Distilled Water to make the product weigh *one thousand* (1000) *grammes*. Lastly, shake the bottle and transfer its contents to small vials, which should be completely filled, securely corked, and kept in a place accessible to daylight.

371. SYRUPUS FERRI CITRO-IODIDI. *N. F.*

Syrup of Ferric Citro-Iodide.

Tasteless Syrup of Iodide of Iron.

Iodine	**59**	**Gm.**
Iron Wire, fine, bright, and finely cut	**28.5**	**Gm.**
Potassium Citrate	**88**	**Gm.**
Sugar	**650**	**Gm.**
Distilled Water, a sufficient quantity		
To make	**1000**	**Cc.**

Mix the Iron with *one hundred and fifty* (150) *cubic centimeters* of Distilled Water in a flask, add *forty-five* (45) *grammes* of the Iodine, apply a gentle heat, and set aside until the Iodine is combined and the solution has acquired a green color. Then heat the contents of the flask to boiling, filter the liquid, and wash the filter with *thirty* (30) *cubic centimeters* of warm Distilled Water. Add to the filtrate the remaining *fourteen* (14) *grammes* of Iodine, and, as soon as solution has been effected, mix with the Potassium Citrate previously dissolved in *one hundred* (100) *cubic centimeters* of Distilled Water, and agitate the liquid until it has assumed a green color. Pour this upon the Sugar contained in a bottle, agitate until solution has been effected, and when the liquid is cold, add enough Distilled Water to make *one thousand* (1000) *cubic centimeters*.

Each fluidrachm contains an amount of Iron corresponding to about 3.6 grains of Ferric Iodide.

372. SYRUPUS FERRI ET MANGANI IODIDI. *N. F.*

Syrup of Ferrous Iodide and Manganese.

Iodine	**81.5**	**Gm.**
Iron Wire, fine, bright, and finely cut	**26.5**	**Gm.**
Manganese Sulphate	**26.5**	**Gm.**
Potassium Iodide	**31.5**	**Gm.**
Sugar	**775**	**Gm.**
Distilled Water, a sufficient quantity		
To make	**1000**	**Cc.**

Mix the Iron with *two hundred and fifty* (250) *cubic centimeters* of Distilled Water in a flask, add the Iodine, and prepare a solution of ferrous iodide, in the usual manner, aiding the process, if necessary, by heating the contents of the flask, at first gently, and finally to boiling. Filter the liquid, through a small filter, directly upon the Sugar, contained in a suitable bottle. Dissolve the Manganese Sulphate in *one hundred and twenty-five* (125) *cubic centimeters* of Distilled Water, and the Potassium Iodide in *one hundred and twenty-five* (125) *cubic centimeters* of Diluted Alcohol, mix the two solutions, and filter into the same bottle which contains the Sugar and the Iron solution. Wash the filter with *thirty* (30) *cubic centimeters* of cold Distilled Water, receiving the washings in the same bottle. Agitate until the Sugar is dissolved, and, if necessary, strain. Finally, make up the volume with Distilled Water to *one thousand* (1000) *cubic centimeters*.

Each fluidrachm contains about 6 grains of Ferrous Iodide and 3 grains of Manganese Iodide.

373. SYRUPUS FERRI HYPOPHOSPHITIS. *N. F.*

Syrup of Ferric Hypophosphite.

Ferric Hypophosphite	**17.5**	**Gm.**
Potassium Citrate	**25**	**Gm.**
Orange Flower Water	**65**	**Cc.**
Syrup (U. S. P.), a sufficient quantity		
To make	**1000**	**Cc.**

Dissolve the Ferric Hypophosphite, with the aid of the Potassium Citrate, in the Orange Flower Water, and add enough Syrup to make *one thousand* (1000) *cubic centimeters*.

Each fluidrachm contains 1 grain of Ferric Hypophosphite.

374. SYRUPUS FERRI LACTOPHOSPHATIS. *N. F.*

Syrup of Lactophosphate of Iron.

Ferrous Lactate	**17.5**	**Gm.**
Phosphoric Acid (85 %, U. S. P.)	**a sufficient quantity.**	
Water	**30**	**Cc.**
Syrup (U. S. P.), a sufficient quantity		
To make	**1000**	**Cc.**

Dissolve the Ferrous Lactate in the Water with the aid of a sufficient quantity of Phosphoric Acid, avoiding an excess, and add enough Syrup to make *one thousand* (1000) *cubic centimeters*.

Each fluidrachm contains 1 grain of Ferrous Lactate, or about 1½ grains of so-called Lactophosphate of Iron.

375. SYRUPUS FERRI PROTOCHLORIDI. *N. F.*

Syrup of Protochloride of Iron.

Syrup of Ferrous Chloride.

Solution of Ferrous Chloride (F. 222)	**50**	**Cc.**
Glycerin	**125**	**Cc.**
Orange Flower Water	**125**	**Cc.**
Syrup (U. S. P.), a sufficient quantity		
To make	**1000**	**Cc.**

Mix the Solution of Ferrous Chloride with the Glycerin and Orange Flower Water, and add enough Syrup to make *one thousand* (1000) *cubic centimeters*.

Each fluidrachm contains about 1 grain of Ferrous Chloride.

376. SYRUPUS FERRI SACCHARATI SOLUBILIS. *N. F.*

Syrup of Soluble Saccharated Iron.

Syrupus Ferri Oxydati Solubilis. (Germ. Pharm.). *Syrup of Saccharated Oxide of Iron. Syrup of Soluble Oxide of Iron.*

Solution of Ferrous Chloride (U. S. P.)	**80**	**Gm.**
Soda (U. S. P.)	**32.5**	**Gm.**
Solution of Soda (U. S. P.)	**a sufficient quantity.**	
Sugar	**300**	**Gm.**
Distilled Water,		
Syrup (U. S. P.), of each, a sufficient quantity		
To make	**1000**	**Gm.**

Dissolve the Soda in *two hundred and ten* (210) *cubic centimeters* of Water; add this solution to the Solution of Ferrous Chloride previously mixed with *seventy* (70) *grammes* of Syrup, and set the mixture aside, during twenty-four hours, in a dark place. Then pour the clear liquid slowly into *sixteen hundred* (1600) *cubic centimeters* of boiling Distilled Water, continue the boiling for a few minutes, and then set the mixture aside during one day, in a dark place, so that it may become clear by settling. Withdraw the supernatant liquid by means of a siphon, then wash the residue again with *sixteen hundred* (1600) *cubic centimeters* of boiling Distilled Water, by decantation. Transfer the magma to a wetted strainer, and wash it with hot Distilled Water, until this runs off colorless,

but so that the mass on the strainer still retains a moderately strong alkaline reaction. Then allow the excess of liquid to drain off, transfer the moist magma to a tared porcelain capsule, add the Sugar, and heat it on a water-bath, with exclusion of daylight, during two hours, replacing from time to time any Water lost by evaporation, and adding, if necessary, Solution of Soda, drop by drop, until the magma is entirely dissolved. Lastly, add enough Syrup to make the product weigh *one thousand* (1000) *grammes*, and transfer the product to bottles, which should be completely filled, and stored in a cool and dark place.

One hundred grains, or about 75 minims, of this Syrup represent approximately 1 grain of metallic Iron.

Note.—The above process is based upon that of the Germ. Pharm. (1st edition). The formula given by the second edition of this work presupposes the keeping in stock of a dry "Ferrum Oxydatum Saccharatum Solubile" (saccharated Oxide of Iron), representing 3 per cent. of metallic iron. When this is available, the *Syrup of Soluble Saccharated Iron* may also be prepared by the following formula:

Saccharated Oxide of Iron,
Syrup,
Water, each . . . . . equal parts.

Dissolve the Saccharated Oxide of Iron in the mixed liquids.

377. SYRUPUS GLYCYRRHIZÆ. *N. F.*

Syrup of Glycyrrhiza.

Syrup of Liquorice.

Pure Extract of Glycyrrhiza (U.S.P.)	125 Gm.
Glycerin	125 Gm.
Sugar	650 Gm.
Water, a sufficient quantity	
To make	1000 Cc.

Dissolve the Pure Extract of Glycyrrhiza in *five hundred* (500) *cubic centimeters* of Water, add the Sugar, dissolve it by agitation, and strain. Then add the Glycerin, and, lastly, enough Water to make *one thousand* (1000) *cubic centimeters*.

Each fluidrachm represents about 30 grains of Glycyrrhiza.

378. SYRUPUS HYPOPHOSPHITUM COMPOSITUS. *N. F.*

Coupound Syrup of Hypophosphites.

Compound Hypophosphites.

Calcium Hypophosphite	35	Gm.
Potassium Hypophosphite	17.5	Gm.
Sodium Hypophosphite	17.5	Gm.
Ferric Hypophosphite	2.25	Gm.
Manganese Hypophosphite	2.25	Gm.
Potassium Citrate	5	Gm.
Citric Acid	2	Gm.
Quinine Hydrochlorate	1.125	Gm.
Tincture of Nux Vomica (U. S. P.)	22	Cc.
Sugar	775	Gm.
Water, a sufficient quantity		
To make	1000	Cc.

Rub the Hypophosphites of Iron and of Manganese with the Potassium Citrate and Citric Acid to powder, add *sixty* (60) *cubic centimeters* of Water, and warm the mixture a few minutes until a clear greenish solution is obtained. Introduce the other Hypophosphites and the Quinine Hydrochlorate, previously triturated together, into a graduated bottle, next add the Sugar, the Iron and Manganese solution first prepared, the Tincture of Nux Vomica, and, lastly, enough Water to make up the volume, as soon as the Sugar is saturated by the liquid, to *one thousand* (1000) *cubic centimeters*. Agitate, until solution has been effected, and strain, if necessary.

Each fluidrachm contains 2 grains of Calcium Hypophosphite, 1 grain, each, of Potassium and Sodium Hypophosphites, $\frac{1}{8}$ grain, each, of the Hypophosphites of Iron and of Manganese, $\frac{1}{16}$ grain of Quinine Hydrochlorate, and 1½ minims of Tincture of Nux Vomica.

379. SYRUPUS IPECACUANHÆ ET OPII. *N. F.*

Syrup of Ipecac and Opium.

Syrup of Dover's Powder.

Fluid Extract of Ipecac (U. S. P.)	8.5	Cc.
Tincture of Deodorized Opium (U. S. P)	85	Cc.
Sugar	775	Gm.
Cinnamon Water (U. S. P.), a sufficient quantity		
To make	1000	Cc.

Mix the Fluid Extract and Tincture with *three hundred and fifty* (350) *cubic centimeters* of Cinnamon Water, and filter the liquid; to this add the Sugar, and enough Cinnamon Water to make the product, after the Sugar has been dissolved by agitation, measure *one thousand* (1000) *cubic centimeters*.

Each fluidrachm represents 5 grains of Dover's Powder, or ½ grain, each, of Ipecac and Opium.

Note.—In place of the above-directed quantities of Fluid Extract of Ipecac and Tincture of Deodorized Opium, *eighty-five* (85) *cubic centimeters* of the official *Tinctura Ipecacuanhæ et Opii* may be taken.

380. SYRUPUS MANNÆ. *N. F.*

Syrup of Manna.

Manna, in flakes	125	Gm.
Sugar	775	Gm.
Alcohol	65	Cc.
Water, a sufficient quantity		
To make	1000	Cc.

Dissolve the Manna in *four hundred and fifty* (450) *cubic centimeters* of hot Water, add the Alcohol, set the liquid aside for twelve hours in a moderately warm place, and filter. Dissolve the Sugar in the filtrate, with the aid of a gentle heat, allow the Syrup to cool, and add enough Water, passed through the filter previously used, to make *one thousand* (1000) *cubic centimeters*.

381. SYRUPUS MORPHINÆ COMPOSITUS. *N. F.*

Compound Syrup of Morphine.

Fluid Extract of Ipecac (U. S. P.)	2	Cc.
Fluid Extract of Senega (U. S. P.)	100	Cc.
Fluid Extract of Rhubarb (U. S. P.)	16	Cc.
Morphine Sulphate	0.55	Gm.
Oil of Sassafras	1	Cc.
Syrup (U. S. P.), a sufficient quantity		
To make	1000	Cc.

Dissolve the Morphine Sulphate in about *sixty* (60) *cubic centimeters* of Syrup, then add the Fluid Extracts and the Oil of Sassafras, and, lastly, enough Syrup to make *one thousand* (1000) *cubic centimeters*. Mix the whole thoroughly by shaking.

Note.—In some sections of the country this preparation is dispensed when Pectoral Syrup or Jackson's Cough Syrup is demanded or ordered. As the formula differs too much from that originally used by Dr. Jackson (see Note to F. 384), it is recommended that the above preparation be dispensed only when it is designated by the title above given.

382. SYRUPUS MORPHINÆ SULPHATIS. *N. F.*

Syrup of Morphine Sulphate.

Syrupus Morphinæ. Syrup of Morphine.

1. Morphine Sulphate	2.2	Gm.
Water, hot	30	Cc.
Syrup (U. S. P.), a sufficient quantity		
To make	1000	Cc.

Dissolve the Morphine Sulphate in the hot Water, and add enough Syrup to make *one thousand* (1000) *cubic centimeters*.

Each fluidrachm contains $\frac{1}{8}$ *grain of Morphine Sulphate.*

Note.—This preparation is in considerable use in the Southern States. It should, however, never be dispensed in prescriptions, unless it is known to be the preparation intended, or unless it is designated as that of the National Formulary (N. F.).

When *Syrup of Morphine* is prescribed without any such specific designation or knowledge, it is recommended that the corresponding, but weaker, preparation of the French Pharm. be dispensed. The official title of this is *Sirop de Chlorhydrate de Morphine* (or *Sirop de Morphine*).

This may be prepared approximately of the strength required by the Codex, as follows:

2 Morphine Hydrochlorate	0.7	Gm.
Water	30	Cc.
Syrup (U. S. P.), a sufficient quantity		
To make	1000	Cc.

Dissolve the Morphine Hydrochlorate in the Water, and add enough Syrup to make *one thousand* (1000) *cubic centimeters.*

Each fluidrachm contains about $\frac{1}{8}$ *grain of Morphine Hydrochlorate.*

383. SYRUPUS PAPAVERIS. *N. F.*

Syrup of Poppy.

Tincture of Poppy (F. 416)	875	Cc.
Sugar	775	Gm.
Water, a sufficient quantity		
To make	1000	Cc.

Evaporate the Tincture of Poppy, on a water-bath, at a gentle heat, until its volume is reduced to *four hundred and fifty* (450) *cubic centimeters.* In this dissolve the Sugar with a gentle heat, strain, and when the Syrup is cold, add enough Water to make *one thousand* (1000) *cubic centimeters.*

Note.—The product is practically identical with the *Syrupus Papaveris* of the Brit. Pharm. The corresponding preparation of the Germ. Pharm. (*Syrupus Papaveris*, or *Syrupus Diacodii*) is much weaker, and may be prepared as follows:

Tincture of Poppy (F. 416)	125	Cc.
Syrup (U. S. P.)	875	Cc.

Mix them.

384. SYRUPUS PECTORALIS. *N. F.*

Pectoral Syrup.

Jackson's Pectoral (or *Cough*) *Syrup.*

Morphine Hydrochlorate	0.55	Gm.
Oil of Sassafras	0.5	Cc.
Syrup of Acacia (U. S. P.), a sufficient quantity		
To make	1000	Cc.

Dissolve the Morphine Hydrochlorate in about *sixty* (60) *cubic centimeters* of the Syrup, add the Oil of Sassafras, and enough Syrup to make *one thousand* (1000) *cubic centimeters.*

Each fluidrachm contains $\frac{1}{32}$ *grain of Morphine Hydrochlorate.*

Note.—The original formula of Dr. Samuel Jackson's Cough Syrup was as follows: Sassafras Pith, 60 grains; Acacia, 1 ounce; Sugar, 28 avounces; Muriate of Morphine, 8 grains; Water, enough to make 32 fluidounces. The Sassafras Pith was afterwards uniformly replaced by Oil of Sassafras, and the other constituents of the Syrup have been more or less altered, so that a number of different formulas are in vogue in different sections of the country. It is recommended that the above be followed, if possible, for the sake of uniformity. (See Note to F. 381.)

385. SYRUPUS PHOSPHATUM COMPOSITUS. *N. F.*

Compound Syrup of the Phosphates.

Chemical Food.

Precipitated Calcium Carbonate	35	Gm.
Soluble Ferric Phosphate (U.S.P.)	17.5	Gm.
Ammonium Phosphate	17.5	Gm.
Potassium Bicarbonate	4	Gm.
Sodium Bicarbonate	4	Gm.
Citric Acid	60	Gm.
Glycerin	65	Cc.
Phosphoric Acid (50 %)	125	Cc.
Orange Flower Water	125	Cc.
Tincture of Cudbear (F. 418)	16	Cc.
Sugar	525	Gm.
Water, a sufficient quantity		
To make	1000	Cc.

Triturate the Precipitated Calcium Carbonate with the Potassium and Sodium Bicarbonates, the Citric Acid, Glycerin, and Orange Flower Water, and gradually add the Phosphoric Acid, stirring until solution has been effected. Dissolve the Ferric Phosphate and the Ammonium Phosphate in *two hundred and fifty* (250) *cubic centimeters* of hot Water, cool, and add the solution to that previously prepared. Filter the whole through a pellet of absorbent cotton placed in the neck of a funnel, and receive the filtrate in a graduated bottle containing the Sugar. Agitate until the latter is dissolved, then add the Tincture of Cudbear, and, lastly, enough Water to make *one thousand* (1000) *cubic centimeters.*

Each fluidrachm contains about 2 grains of Calcium Phosphate, 1 grain, each, of the Phosphates of Iron and of Ammonium, and smaller quantities of Potassium and Sodium Phosphates.

Note.—Phosphoric Acid (50 %) may be made by adding *seventy* (70) *grammes* of Distilled Water to *one hundred* (100) *grammes* of Phosphoric Acid (U. S. P.), which contains 85 %, by weight, of absolute Orthophosphoric Acid (H_3PO_4).

386. SYRUPUS PINI STROBI COMPOSITUS. *N. F.*

Compound Syrup of White Pine.

White Pine Bark (Pinus Strobus)	75	Gm.
Wild Cherry Bark	75	Gm.
Spikenard Root	10	Gm.
Balm of Gilead Buds	10	Gm.
Sanguinaria Root	8	Gm.
Sassafras Bark	7	Gm.
Morphine Sulphate	0.5	Gm.
Chloroform	6	Cc.
Sugar	750	Gm.
Alcohol,		
Water,		
Syrup (U. S. P.), of each, a sufficient quantity		
To make	1000	Cc.

Reduce the vegetable drugs to a moderately coarse (No. 40) powder, moisten the powder with a menstruum composed of 1 volume of Alcohol and 3 volumes of Water, and macerate for 12 hours. Then percolate with the same menstruum until *five hundred* (500) *cubic centimeters* of tincture have been obtained, in which dissolve the Sugar and the Morphine Sulphate; lastly, add the Chloroform, and sufficient Syrup to make *one thousand* (1000) *cubic centimeters*, and strain.

387. SYRUPUS RHAMNI CATHARTICÆ. *N. F.*

Syrup of Rhamnus Cathartica.

Syrup of Buckthorn Berries. Syrupus Spinæ Cervinæ.

Sugar	800	Gm.
Fermented Juice of Buckthorn Berries, a sufficient quantity		
To make	1000	Cc.

Dissolve the Sugar in *four hundred and fifty* (450) *cubic centimeters* of the Juice, with the aid of a gentle heat, allow the Syrup to cool, then add enough of the Juice to make *one thousand* (1000) *cubic centimeters*, and strain, if necessary.

Note.—This preparation is practically identical with that official in the Germ. Pharm. The species of Buckthorn to be used is the *Rhamnus cathartica* Linné, native of Europe, and naturalized, to some extent, in the U. S. If the fresh berries cannot be obtained, the imported fermented juice may be used in preparing the Syrup.

388. SYRUPUS RHEI ET POTASSII COMPOSITUS. *N. F.*

Compound Syrup of Rhubarb and Potassa.

Neutralizing Cordial.

Fluid Extract of Rhubarb (U. S. P.)	17.5 Cc.
Fluid Extract of Hydrastis (U. S. P.)	8.5 Cc.
Potassium Carbonate	17.5 Gm.
Tincture of Cinnamon (U. S. P.)	65 Cc.
Spirit of Peppermint (U. S. P.)	8 Cc.
Syrup (U. S. P.)	250 Cc.
Diluted Alcohol (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Dissolve the Potassium Carbonate in the Syrup, and add the solution to the Fluid Extracts, Tincture, and Spirit, previously mixed with *six hundred* (600) *cubic centimeters* of Diluted Alcohol. Mix well, add enough Diluted Alcohol to make *one thousand* (1000) *cubic centimeters*, and filter, if necessary.

389. SYRUPUS RUBI AROMATICUS. *N. F.*

Aromatic Syrup of Blackberry.

Rubus (U. S. P.)	125 Gm.
Cinnamon	15 Gm.
Nutmeg	15 Gm.
Cloves	8 Gm.
Allspice	8 Gm.
Sugar	650 Gm.
Diluted Alcohol (U. S. P.), Blackberry Juice, of each, a sufficient quantity	
To make	1000 Cc.

Reduce the Rubus (Blackberry Root) and the Aromatics to a moderately coarse (No. 40) powder, and percolate it, in the usual manner, with the Diluted Alcohol, until *two hundred and fifty* (250) *cubic centimeters* of percolate are obtained. To this add *four hundred and fifty* (450) *cubic centimeters* of Blackberry Juice, and dissolve the Sugar in the liquid by agitation. Lastly, add enough Blackberry Juice to make *one thousand* (1000) *cubic centimeters*.

390. SYRUPUS SANGUINARIÆ. *N. F.*

Syrup of Sanguinaria.

Syrup of Bloodroot.

Sanguinaria, in No. 20 powder	225 Gm.
Acetic Acid (U. S. P.)	125 Cc.
Sugar	800 Gm.
Water, a sufficient quantity	
To make	1000 Cc.

Mix the Acetic Acid with *three hundred and seventy-five* (375) *cubic centimeters* of Water, moisten the Sanguinaria with a sufficient quantity of this menstruum, and allow it to macerate for two hours. Then pack it in a glass percolator, and percolate in the usual manner, first with the remainder of the menstruum previously prepared, and afterwards with Water, until *seven hundred and fifty* (750) *cubic centimeters* of percolate are obtained, or until the Sanguinaria is practically exhausted. Evaporate the percolate, at a moderate heat, to *four hundred and fifty* (450) *cubic centimeters*. In this dissolve the Sugar, with a gentle heat, if necessary, and add enough Water to make *one thousand* (1000) *cubic centimeters*.

Each fluidrachm represents about 13 *grains of Sanguinaria.*

391. SYRUPUS SENNÆ AROMATICUS. *N. F.*

Aromatic Syrup of Senna.

Senna	125 Gm.
Jalap	50 Gm.
Rhubarb	17.5 Gm.
Cinnamon	4 Gm.
Cloves	4 Gm.
Nutmeg	2 Gm.
Oil of Lemon	1.5 Cc.
Sugar	750 Gm.
Diluted Alcohol (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Reduce the drugs to a moderately fine (No. 50) powder, add to it the Oil of Lemon, and percolate it, in the usual manner, with Diluted Alcohol. Remove the first *five hundred* (500) *cubic centimeters* of the percolate, and dissolve in this the Sugar, with the aid of a gentle heat, if necessary, but avoiding loss of alcohol by evaporation. Allow the solution to cool, collect a further portion of percolate, and add it to the Syrup, so as to make *one thousand* (1000) *cubic centimeters*.

Each fluidrachm represents 7½ *grains of Senna,* 3 *grains of Jalap, and* 1 *grain of Rhubarb, with aromatics.*

392. SYRUPUS SENNÆ COMPOSITUS.

Compound Syrup of Senna.

Fluid Extract of Senna (U. S. P.)	135 Cc.
Fluid Extract of Rhubarb (U. S. P.)	35 Cc.
Fluid Extract of Frangula (U. S. P.)	35 Cc.
Oil of Gaultheria	4 Cc.
Alcohol	60 Cc.
Syrup (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Dissolve the Oil of Gaultheria in the Alcohol, and add this to the mixed Fluid Extracts. Then add enough Syrup to make *one thousand* (1000) *cubic centimeters*, and mix by agitation.

Each fluidrachm represents 8 *grains of Senna,* 2 *grains of Rhubarb, and* 2 *grains of Frangula.*

393. SYRUPUS SODII HYPOPHOSPHITIS. *N. F.*

Syrup of Sodium Hypophosphite.

Sodium Hypophosphite	35 Gm.
Citric Acid	1.5 Gm.
Sugar	775 Gm.
Water, a sufficient quantity	
To make	1000 Cc.

Dissolve the Sodium Hypophosphite and the Citric Acid in *five hundred* (500) *cubic centimeters* of Water, and filter the solution. In this dissolve the Sugar by agitation, and pass enough Water through the filter to make the product measure *one thousand* (1000) *cubic centimeters*.

Each fluidrachm contains 2 *grains of Sodium Hypophosphite.*

394. SYRUPUS STILLINGIÆ COMPOSITUS. *N. F.*

Compound Syrup of Stillingia.

Compound Fluid Extract of Stillingia (F. 176)	250 Cc.
Purified Talcum (F. 395)	15 Gm.
Sugar	700 Gm.
Water, a sufficient quantity	
To make	1000 Cc.

Mix the Compound Fluid Extract of Stillingia with the Purified Talcum, and afterwards with *two hundred and seventy-five* (275) *cubic centimeters* of Water, and shake them together thoroughly. Then pour the mixture upon a wetted filter, add the Sugar to the filtrate, and pass enough Water through the filter to make the product, after the Sugar has been dissolved by agitation, measure *one thousand* (1000) *cubic centimeters*.

Each fluidrachm represents 15 *minims of Compound Fluid Extract of Stillingia* (*see F.* 176).

395. TALCUM PURIFICATUM. *N. F.*

Purified Talcum.

Talcum, in fine powder	100 parts.
Hydrochloric Acid	15 parts.
Water	a sufficient quantity.

Mix *five hundred* (500) *parts* of boiling Water with the Talcum, gradually add *ten* (10) *parts* of the Hydrochloric Acid, and boil the mixture during fifteen minutes. Then allow the suspended Talcum to subside, pour off the supernatant liquid, and boil the residue again with *five hundred* (500) *parts* of Water mixed with the remainder of the Hydrochloric Acid. Again allow the mixture to become clear by settling, pour off the supernatant liquid, and wash the residue with Water, by repeated decantation, until a portion of the wash-water, filtered and placed in a test-tube, ceases to produce a precipitate with test-solution of silver nitrate acidified with nitric acid. Then transfer the magma to a close linen or muslin strainer, allow it to drain, and dry it by heat.

Note.—Purified Talcum is used as an aid in filtering turbid liquids containing finely-divided matters in suspension, which are apt to pass through the filter, or to stop up its pores.

396. TINCTURÆ. *N. F.*

Tinctures.

General Process.—All Tinctures for which no working formula is provided by the U. S. Pharmacopœia, the National Formulary, or some other work of authority, and the strength of which is not otherwise specified by the prescriber, should be prepared in the following proportions:

The Drug, properly comminuted	**125 Gm.**
The Menstruum, enough to make	**1000 Cc.**

397. TINCTURA ACONITI, FLEMING. *N. F.*

Fleming's Tincture of Aconite.

Aconite (root), in fine powder	**700 Gm.**
Alcohol, a sufficient quantity	
To make	**1000 Cc.**

Moisten the Aconite with enough Alcohol to render it distinctly damp and to maintain it so after twenty-four hours' maceration in a well-covered vessel. Then pack it tightly in a percolator, and percolate it slowly, in the usual manner, with Alcohol, until *one thousand* (1000) *cubic centimeters* of tincture are obtained.

Note.—This preparation is still prescribed by many physicians. It is recommended that their attention be directed to the official Fluid Extract and Tincture of Aconite, so that the above preparation may be gradually abandoned.

When this preparation is required for immediate use, and it is not otherwise available, it may be prepared in the following manner:

Fluid Extract of Aconite (U. S. P.)	**70 Cc.**
Alcohol	**30 Cc.**

Mix them.

398. TINCTURA AMARA. *N. F.*

Bitter Tincture.

Stomachic Tincture. Bitter Stomachic Drops. Stomach Drops.

Gentian	**50 Gm.**
Centaury, herb	**50 Gm.**
Bitter Orange Peel	**35 Gm.**
Orange Berries	**17 Gm.**
Zedoary, root	**17 Gm.**
Alcohol,	
Water, of each, a sufficient quantity	
To make	**1000 Cc.**

Reduce the drugs to a moderately coarse (No. 40) powder, and percolate it, in the usual manner, with a mixture of *two* (2) *volumes* of Alcohol and *one* (1) *volume* of Water, until *one thousand* (1000) *cubic centimeters* of percolate are obtained.

399. TINCTURA ANTACRIDA. *N. F.*

Antacrid Tincture.

Dysmenorrhœa Mixture. Fenner's Guaiac Mixture.

Corrosive Chloride of Mercury	**5.5 Gm.**
Guaiac (U. S. P.), in fine powder	**125 Gm.**
Canada Turpentine	**125 Gm.**
Oil of Sassafras	**30 Cc.**
Alcohol, a sufficient quantity	
To make	**1000 Cc.**

Introduce the Guaiac and the Canada Turpentine into a flask, together with *seven hundred and fifty* (750) *cubic centimeters* of Alcohol, cork the flask loosely, and heat the contents, on a water-bath, slowly to boiling. Then cool the flask, and filter the contents through a small filter. Dissolve the Corrosive Chloride of Mercury in *thirty* (30) *cubic centimeters* of Alcohol, and add this solution, as well as the Oil of Sassafras, to the filtrate. Lastly, pass enough Alcohol through the filter to make the product measure *one thousand* (1000) *cubic centimeters.*

Each fluidrachm contains nearly $\frac{1}{8}$ *grain of Corrosive Chloride of Mercury.*

Note.—The dose of this preparation is about 10 to 20 minims.

400. TINCTURA ANTIPERIODICA. *N. F.*

Antiperiodic Tincture.

Warburg's Tincture.

1. *Without Aloes.*

Rhubarb	**36 Gm.**
Angelica, seed	**36 Gm.**
Elecampane	**18 Gm.**
Saffron	**18 Gm.**
Fennel	**18 Gm.**
Gentian	**9 Gm.**
Zedoary, root	**9 Gm.**
Cubeb	**9 Gm.**
Myrrh	**9 Gm.**
White Agaric	**9 Gm.**
Camphor	**9 Gm.**
Quinine Sulphate	**100 Gm.**
Diluted Alcohol (U. S. P.), a sufficient quantity	
To make	**5000 Cc.**

Reduce the fibrous vegetable drugs to a coarse (No. 20) powder, mix this with the Myrrh and Camphor, previously powdered, and digest the whole, during twelve hours, in a suitable, well-covered vessel, with *forty-two hundred and fifty* (4250) *cubic centimeters* of Diluted Alcohol, on a water-bath, avoiding, as much as possible, any loss of Alcohol by evaporation. Then strain off the liquid with pressure, dissolve the Quinine Sulphate in the strained liquid, with a gentle heat, if necessary, filter, and pass enough Diluted Alcohol, first through the strainer and then through the filter, to make the product measure *five thousand* (5000) *cubic centimeters.*

Each fluidounce contains 10 *grains of Quinine Sulphate.*

Note.—This preparation, made *without Aloes*, is intended to serve as a stock-tincture, from which the regular "Warburg's Tincture" is to be made, when required. "Warburg's Tincture without Aloes" is also often prescribed or asked for, and in this case the above preparation is to be dispensed.

The original formula directed by Dr. Warburg contained the old *Confectio Damocratis* as one of the ingredients. This is a very complex preparation, many of the constituents of which are unobtainable at the present day. It has, therefore, been omitted.

2. *With Aloes.*

Extract of Aloes (U. S. P.)	**17.5 Gm.**
Antiperiodic Tincture, without Aloes	**1000 Cc.**

Dissolve the Extract in the Tincture.

Note.—When "Warburg's Tincture," without any further specification, is ordered, this preparation (containing Aloes) is to be dispensed.

401. TINCTURA AROMATICA. *N. F.*

Aromatic Tincture.

Cinnamon (Cassia)	**85 Gm.**
Ginger	**36 Gm.**
Galangal, root	**18 Gm.**
Cloves	**18 Gm.**
Cardamom	**18 Gm.**
Alcohol,	
Water, of each, a sufficient quantity	
To make	**1000 Cc.**

Reduce the drugs to a moderately coarse (No. 40) powder, and percolate it, in the usual manner, with a mixture of *two* (2) *volumes* of Alcohol and *one* (1) *volume* of Water, until *one thousand* (1000) *cubic centimeters* of percolate are obtained.

402. TINCTURA CAPSICI ET MYRRHÆ. *N. F.*

Tincture of Capsicum and Myrrh.

Hot Drops.

Capsicum, in No. 20 powder	32 Gm.
Myrrh, in moderately coarse powder	125 Gm.
Alcohol,	
Water, of each, a sufficient quantity	
To make	1000 Cc.

Mix the powders with an equal bulk of clean, fine sand, and percolate them, in the usual manner, with a mixture of *nine* (9) *volumes* of Alcohol, and *one* (1) *volume* of Water, until *one thousand* (1000) *cubic centimeters* of percolate are obtained.

Note.—This preparation is known in some parts of this country by the old Thompsonian name "Number six."

403. TINCTURA CINCHONÆ DETANNATA. *N. F.*

Detannated Tincture of Cinchona.

Fluid Extract of Cinchona (U. S. P.)	185 Cc.
Alcohol	500 Cc.
Solution of Ferric Sulphate (U. S. P.)	375 Cc.
Ammonia Water (U. S. P.)	375 Cc.
Water,	
Diluted Alcohol (U. S. P.), of each, a sufficient quantity	
To make	1000 Cc.

To the Ammonia Water, diluted with *fifteen hundred* (1500) *cubic cemtimeters* of Water, gradually add the Solution of Ferric Sulphate, previously diluted with *twenty-five hundred* (2500) *cubic centimeters* of Water, under constant stirring. Pour this mixture, containing Ferric Hydrate as a precipitate, upon a wet muslin strainer (which has been tared, after having been wetted and deprived of the excess of water by moderate pressure), and when the liquid has drained off, return the precipitate to the vessel, and mix it intimately with about *four thousand* (4000) *cubic centimeters* of water. Again drain it on the strainer, transfer it once more to the vessel, and treat it as before. Finally drain and press the precipitate on the strainer until it weighs *five hundred* (500) *grammes*.

Mix the Fluid Extract of Cinchona with *five hundred* (500) *cubic centimeters* of Alcohol, and add the Ferric Hydrate previously prepared. Agitate the mixture frequently, until the tincture is deprived of tannin, which may be known by the absence of a blackish-green color when a small portion of the clear tincture is treated with a drop or two of tincture of ferric chloride. Insert a plug of absorbent cotton into a suitable percolator, and introduce the mixture. As soon as the liquid has disappeared from the surface, pour on enough Diluted Alcohol to make the product measure *one thousand* (1000) *cubic centimeters*.

Note.—This preparation is practically identical, in strength of Cinchona (without the tannin), with the official *Tinctura Cinchonæ*.

404. TINCTURA CONII. *N. F.*

(U. S. P., 1880.)

Tincture of Conium.

Conium (fruit), in No. 30 powder	150 Gm.
Diluted Hydrochloric Acid	4 Cc.
Diluted Alcohol, a sufficient quantity	
To make	1000 Cc.

Moisten the powder with *fifty* (50) *cubic centimeters* of Diluted Alcohol, previously mixed with the Diluted Hydrochloric Acid, and macerate for twenty-four hours; then pack it moderately in a conical glass percolator, and gradually pour Diluted Alcohol upon it until *one thousand* (1000) *cubic centimeters* of Tincture are obtained.

405. TINCTURA COTO. *N. F.*

Tincture of Coto.

Coto (bark), bruised	125 Gm.
Alcohol, a sufficient quantity	
To make	1000 Cc.

Macerate the Coto with *eight hundred and fifty* (850) *cubic centimeters* of Alcohol during seven days; then pour off the liquid, press the residue, and filter the united liquids through paper. Lastly, wash the residue transferred to the filter with enough Alcohol to make the product measure *one thousand* (1000) *cubic centimeters*.

Note.—Coto bark is derived from an undetermined tree, probably belonging to the natural order Lauraceæ, and is obtained from Bolivia. There are two varieties known, one as "Coto," and the other as "Paracoto" bark. True Coto bark is, at times, difficult to obtain in the market, and the Paracoto bark is then frequently substituted for it. While they possess some useful properties in common, yet they differ materially in other respects. Hence, the Paracoto bark should not be substituted for the true Coto bark.

406. TINCTURA FERRI CHLORIDI ÆTHEREA. *N. F.*

Ethereal Tincture of Ferric Chloride.

Bestucheff's Tincture. Lamotte's Drops.

Solution of Ferric Chloride (U. S. P.)	45 Cc.
Ether (U. S. P.)	250 Cc.
Alcohol, a sufficient quantity	
To make	1000 Cc.

Mix the Solution of Ferric Chloride with *six hundred* (600) *cubic centimeters* of Alcohol, add the Ether, and, lastly, enough Alcohol to make *one thousand* (1000) *cubic centimeters*. Introduce the Tincture into bottles made of white (flint) glass, which should not be entirely filled. Cork them tightly and expose them to the rays of the sun, until the Tincture has been completely decolorized. Then remove the bottles to a shady place, and open them occasionally, until the contents have again assumed a yellow color. Lastly, transfer the tincture to bottles, which should be well stoppered and kept in a cool and dark place.

Each fluidrachm represents about ½ grain of metallic Iron.

407. TINCTURA FERRI CITRO-CHLORIDI. *N. F.*

Tincture of Ferric Citro-Chloride.

Tasteless Tincture of Chloride of Iron. Tasteless Tincture of Iron.

Solution of Ferric Chloride (U. S. P.)	250 Cc.
Sodium Citrate	460 Gm.
Alcohol	160 Cc.
Water, a sufficient quantity	
To make	1000 Cc.

Mix the Solution of Ferric Chloride with *two hundred and fifty* (250) *cubic centimeters* of Water, and dissolve in this mixture the Sodium Citrate with the aid of a gentle heat. Then add the Alcohol, and when the solution has become cold, make up the volume with Water to *one thousand*(1000) *cubic centimeters*. Set the product aside in a cold place for a few days, if convenient, so that the excess of saline matter may separate. Then filter, and pass enough cold Water through the filter to restore the original volume.

Each fluidrachm contains an amount of Iron equivalent to about 7½ grains of dry Ferric Chloride.

Note.—This preparation is practically identical in the strength of iron, but not in the quantity of alcohol, with the official *Tinctura Ferri Chloridi*.

408. TINCTURA FERRI POMATA. *N. F.*

Tincture of Ferrated Extract of Apples.

Tinctura Ferri Malatis Crudi. Tincture of Crude Malate of Iron.

Ferrated Extract of Apples (F. 156)	100 Gm.
Alcohol	100 Cc.
Cinnamon Water (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Dissolve the Ferrated Extract of Apples in *seven hundred and fifty* (750) *cubic centimeters* of Cinnamon Water, add the Alcohol, filter, and pass enough Cinnamon Water through the filter to make *one thousand* (1000) *cubic centimeters.*

Each fluidrachm represents about ⅛ grain of metallic Iron.

409. TINCTURA GUAIACI COMPOSITA. *N. F.*

Compound Tincture of Guaiac.

Dewees's Tincture of Guaiac.

Guaiac (U. S. P.)	125 Gm.
Potassium Carbonate	6 Gm.
Pimenta, in moderately fine powder	30 Gm.
Pumice, in fine powder	60 Gm.
Alcohol	435 Cc.
Water	435 Cc.
Diluted Alcohol, a sufficient quantity	
To make	1000 Cc.

Triturate the Guaiac and Potassium Carbonate with the Pimenta and the Pumice, and afterwards gradually with the Alcohol. Next add slowly *four hundred and thirty-five* (435) *cubic centimeters* of cold Water and triturate the mixture thoroughly. Then filter, and pass enough Diluted Alcohol through the filter to make *one thousand* (1000) *cubic centimeters.*

Each fluidrachm represents 7½ grains of Guaiac.

410. TINCTURA IGNATIÆ. *N. F.*

(U. S. P., 1880.)

Tincture of Ignatia.

Ignatia, in No. 60 powder	10 Gm.
Alcohol,	
Water, of each	a sufficient quantity.

Mix Alcohol and Water in the proportion of *eight* (8) *parts* by weight of Alcohol to *one* (1) *part* of Water. Moisten the Powder with *ten* (10) *grammes* of the menstruum, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour menstruum upon it, until the Ignatia is exhausted. Reserve the first *ninety* (90) *grammes*, evaporate the remainder to *ten* (10) *grammes*, and mix with the reserved portion. Of this tincture take any convenient number of parts, and, by means of a water-bath, evaporate it to dryness. Weigh the resulting extract, and from its weight calculate the quantity of extract contained in the *one hundred* (100) *parts* of Tincture obtained; then dissolve the dried extract in the remainder of the Tincture, and add enough of the above menstruum to make the product weigh so many parts that each *one hundred* (100) *parts* of Tincture shall contain *one* (1) *part* of dry extract. Lastly, mix thoroughly, and filter through paper.

Tincture of Ignatia thus prepared represents about 10 *grammes of Ignatia in* 100 *grammes.*

411. TINCTURA IODI, CHURCHILL. *N. F.*

Churchill's Tincture of Iodine.

Iodine	165 Gm.
Potassium Iodide	33 Gm.
Water	250 Cc.
Alcohol, a sufficient quantity	
To make	1000 Cc.

Dissolve the Potassium Iodide in the Water, then add the Iodine, and, lastly, enough Alcohol to make the Tincture, when completed, measure *one thousand* (1000) *cubic centimeters.*

Note.—Churchill's Tincture of Iodine should not be confounded with Churchill's Iodine Caustic (*Liquor Iodi Causticus*, F. 227).

412. TINCTURA IODI DECOLORATA. *N. F.*

Decolorized Tincture of Iodine.

Iodine	83 Gm.
Sodium Hyposulphite	83 Gm.
Water	100 Cc.
Stronger Ammonia Water (U. S. P.)	65 Cc.
Alcohol, a sufficient quantity	
To make	1000 Cc.

Digest the Iodine, Sodium Hyposulphite, and Water, at a gentle heat, until a perfect solution, of a dark reddish-brown color, is produced. Then add *one hundred and twenty-five* (125) *cubic centimeters* of Alcohol, and afterwards, the Stronger Ammonia Water. Shake a few minutes until no more bubbles of gas escape, and the liquid has become colorless, with a whitish precipitate (of sulphur) suspended in it. Cool it, if necessary, and add enough Alcohol to make *one thousand* (1000) *cubic centimeters.* Place the bottle containing it in a refrigerator for a few hours, or longer if convenient, then filter, in a covered funnel, and preserve the liquid for use.

Note.—On prolonged standing a crystalline precipitate, of sodium tetrathionate, will usually form in the liquid. This may be removed by filtration.

413. TINCTURA JALAPÆ. *N. F.*

Tincture of Jalap.

Jalap, in fine powder	200 Gm.
Alcohol,	
Water, of each, a sufficient quantity	
To make	1000 Cc.

Mix *two* (2) *volumes* of Alcohol with *one* (1) *volume* of Water. Percolate the Jalap with this mixture, in the usual manner, until *one thousand* (1000) *cubic centimeters* of the Tincture are obtained.

414. TINCTURA JALAPÆ COMPOSITA. *N. F.*

Compound Tincture of Jalap.

Jalap, in fine powder	125 Gm.
Scammony, in powder	32 Gm.
Alcohol,	
Water, of each, a sufficient quantity	
To make	1000 Cc.

Mix *two* (2) *volumes* of Alcohol with *one* (1) *volume* of Water. Mix the powders with half their weight of sand; moisten the mixture with a sufficient quantity of the menstruum, pack it in a percolator, and percolate it with the menstruum, in the usual manner, until *one thousand* (1000) *cubic centimeters* of Tincture are obtained.

415. TINCTURA KINO COMPOSITA. *N. F.*

Compound Tincture of Kino.

Tincture of Kino (U. S. P.)	100 Cc.
Tincture of Opium (U. S. P.)	100 Cc.
Spirit of Camphor (U. S. P.)	65 Cc.
Oil of Cloves	1.5 Cc.
Cochineal, in powder	9 Gm.
Aromatic Spirit of Ammonia (U. S. P.)	8 Cc.
Diluted Alcohol (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Triturate the Cochineal with the Aromatic Spirit of Ammonia, and gradually add *seven hundred* (700) *cubic centimeters* of Diluted Alcohol. Then add the two Tinctures, the Spirit of Camphor, and the Oil of Cloves, and

filter the mixture through paper. Lastly, pass enough Diluted Alcohol through the filter to make *one thousand* (1000) *cubic centimeters.*

Each fluidrachm represents about ½ grain, each, of Kino and of Powdered Opium.

416. TINCTURA PAPAVERIS. *N. F.*

Tincture of Poppy.

Poppy Capsules, freed from seeds, and in coarse powder	**500 Gm.**
Glycerin	**125 Cc.**
Alcohol,	
Water, of each, a sufficient quantity	
To make	**1000 Cc.**

Digest the Poppy capsules with *three thousand* (3000) *cubic centimeters* of boiling Water during two hours, then express and strain. Evaporate the strained liquid to *five hundred* (500) *cubic centimeters,* mix it with *two hundred and fifty* (250) *cubic centimeters* of Alcohol, and set the mixture aside, well covered, until it is quite cold. Then filter, add the Glycerin to the filtrate, and pass enough of a mixture of *two* (2) *volumes* of Water and *one* (1) *volume* of Alcohol through the filter to make the product measure *one thousand* (1000) *cubic centimeters.*

Each fluidrachm represents 30 grains of Poppy (Capsule) freed from seeds.

417. TINCTURA PECTORALIS. *N. F.*

Pectoral Tincture.

Guttæ Pectorales. Pectoral Drops. Bateman's Pectoral Drops.

Tincture of Opium (U. S. P.)	**42 Cc.**
Compound Tincture of Catechu (U. S. P.)	**30 Cc.**
Spirit of Camphor (U. S. P.)	**40 Cc.**
Oil of Anise	**1 Cc.**
Caramel	**16 Cc.**
Diluted Alcohol (U. S. P.), a sufficient quantity	
To make	**1000 Cc.**

Mix the first five ingredients with enough Diluted Alcohol to make *one thousand* (1000) *cubic centimeters,* and filter.

Each fluidrachm contains 2½ minims of Tincture of Opium.

418. TINCTURA PERSIONIS. *N. F.*

Tincture of Cudbear.

Cudbear, in fine powder	**125 Gm.**
Alcohol,	
Water, of each, a sufficient quantity	
To make	**1000 Cc.**

Pack the Cudbear in a suitable percolator, and percolate it with a mixture of *one* (1) *volume* of Alcohol and *two* (2) *volumes* of Water, until *one thousand* (1000) *cubic centimeters* of Tincture are obtained.

Note.—This preparation is intended as a coloring agent when a bright-red tint or color is to be produced, particularly in acid liquids.

419. TINCTURA PERSIONIS COMPOSITA. *N. F.*

Compound Tincture of Cudbear.

Cudbear	**20 Gm.**
Caramel	**100 Gm.**
Alcohol,	
Water, of each, a sufficient quantity	
To make	**1000 Cc.**

Mix *one* (1) *volume* of Alcohol with *two* (2) *volumes* of Water. Macerate the Cudbear with *seven hundred and fifty* (750) *cubic centimeters* of the menstruum, during twelve hours, agitating occasionally, and then filter through paper, and add the Caramel, previously dissolved in *one hundred and twenty-five* (125) *cubic centimeters* of Water. Then pass enough of the before-mentioned menstruum through the filter to make the whole measure *one thousand* (1000) *cubic centimeters.*

Note.—This preparation is intended as a coloring agent when a brownish-red tint or color is to be produced.

420. TINCTURA PIMPINELLÆ. *N. F.*

Tincture of Pimpinella.

Pimpinella, root	**165 Gm.**
Alcohol,	
Water, of each, a sufficient quantity	
To make	**1000 Cc.**

Mix *two* (2) *volumes* of Alcohol with *one* (1) *volume* of Water. Macerate the Pimpinella, reduced to a moderately coarse (No. 40) powder, with enough of the menstruum to keep it distinctly damp during twelve hours. Then percolate it with the same menstruum, in the usual manner, until *one thousand* (1000) *cubic centimeters* of Tincture are obtained.

421. TINCTURA RHEI AQUOSA. *N. F.*

Aqueous Tincture of Rhubarb.

Rhubarb	**100 Gm.**
Sodium Borate	**10 Gm.**
Potassium Carbonate	**10 Gm.**
Cinnamon Water (U. S. P.)	**150 Cc.**
Alcohol	**120 Cc.**
Water, a sufficient quantity	
To make	**1000 Cc.**

Dissolve the Sodium Borate and the Potassium Carbonate in *seven hundred* (700) *cubic centimeters* of Water, and macerate in this solution, during twenty-four hours, the Rhubarb, cut into thin slices and carefully freed from any adhering fine powder. Then strain it through muslin, heat the strained liquid to boiling, add the Cinnamon Water and Alcohol, stir it well and filter, while warm, in a covered funnel. To the cold filtrate add enough Water to make the product measure *one thousand* (1000) *cubic centimeters.*

Each fluidrachm represents about 5⅜ grains of Rhubarb.

Note.—The product is practically identical with that obtained by the process of the Germ. Pharm., in which this preparation is official. It is liable to deteriorate when kept too long, and should not be prepared in larger quantity than may be consumed within a short time.

When this preparation is required for immediate use, and it is not otherwise obtainable, it may be prepared in the following manner;

Fluid Extract of Rhubarb (U. S. P.)	**100 Cc.**
Sodium Borate	**10 Gm.**
Potassium Carbonate	**10 Gm.**
Cinnamon Water (U. S. P.)	**150 Cc.**
Alcohol	**75 Cc.**
Water, a sufficient quantity	
To make	**1000 Cc.**

Dissolve the Sodium Borate and the Potassium Carbonate in about *five hundred* (500) *cubic centimeters* of Water. Add the Cinnamon Water, Alcohol, and Fluid Extract of Rhubarb, and, lastly, enough Water to make the product measure *one thousand* (1000) *cubic centimeters.* Filter, if necessary.

422. TINCTURA RHEI ET GENTIANÆ. *N. F.*

Tincture of Rhubarb and Gentian.

Rhubarb	**70 Gm.**
Gentian	**17.5 Gm.**
Diluted Alcohol (U. S. P.), a sufficient quantity	
To make	**1000 Cc.**

Reduce the solids to a moderately coarse (No. 40) powder, and percolate it, in the usual manner, with Diluted Alcohol, until *one thousand* (1000) *cubic centimeters* of percolate are obtained.

Each fluidrachm represents 4 grains of Rhubarb and 1 grain of Gentian.

Note.—When this preparation is required for immediate use, and it is not otherwise obtainable, it may be prepared in the following manner:

Fluid Extract of Rhubarb (U. S. P.)	70 Cc.
Fluid Extract of Gentian (U. S. P.)	17.5 Cc.
Diluted Alcohol (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Mix the Fluid Extracts with enough Diluted Alcohol to make *one thousand* (1000) *cubic centimeters*, and filter.

423. TINCTURA RHEI VINOSA. *N. F.*

Vinous Tincture of Rhubarb.

Fluid Extract of Rhubarb (U. S. P.)	80 Cc.
Fluid Extract of Bitter Orange Peel (U. S. P.)	20 Cc.
Tincture of Cardamom (U. S. P.)	80 Cc.
Sugar	125 Gm.
Sherry Wine, a sufficient quantity	
To make	1000 Cc.

Mix the Fluid Extracts and the Tincture with *five hundred* (500) *cubic centimeters* of Sherry Wine. In this dissolve the Sugar by agitation, then add enough Sherry Wine to make *one thousand* (1000) *cubic centimeters*, and filter.

424. TINCTURA SAPONIS VIRIDIS COMPOSITA. *N. F.*

Compound Tincture of Green Soap.

Soft Soap (U. S. P.)	150 Gm.
Oil of Cade	20 Cc.
Alcohol, a sufficient quantity	
To make	1000 Cc.

Dissolve the Soft Soap in *seven hundred and fifty* (750) *cubic centimeters* of Alcohol, add the Oil of Cade, and then enough Alcohol to make the product measure *one thousand* (1000) *cubic centimeters*, and filter.

425. TINCTURA TOLUTANA SOLUBILIS. *N. F.*

Soluble Tincture of Tolu.

Balsam of Tolu	100 Gm.
Magnesium Carbonate	10 Gm.
Glycerin	400 Cc.
Water, Alcohol, of each, a sufficient quantity	
To make	1000 Cc.

Mix *two hundred* (200) *cubic centimeters* of Alcohol with the Glycerin, and dissolve the Balsam of Tolu in the mixture with the aid of heat, avoiding loss by evaporation. Next add *four hundred* (400) *cubic centimeters* of Water, and allow the mixture to become cold. Pour off the milky liquid from the resinous precipitate (which latter is to be rejected), mix it with the Magnesium Carbonate, by trituration, and filter. Lastly, pass enough of a mixture of *one* (1) *volume* of Alcohol and *two* (2) *volumes* of Water through the filter, to make the whole filtrate measure *one thousand* (1000) *cubic centimeters*.

Note.—This preparation may be added to Syrup or Water without producing cloudiness. A mixture of 1 fluidounce of this preparation with 15 fluidounces of Syrup yields a product which may be used as Syrup of Tolu in all cases where the official preparation is not required.

426. TINCTURA VANILLINI COMPOSITA. *N. F.*

Compound Tincture of Vanillin.

Compound Essence of Vanillin.

Vanillin	6.5 Gm.
Cumarin	0.4 Gm.
Alcohol	200 Cc.
Glycerin	125 Cc.
Syrup (U. S. P.)	125 Cc.
Compound Tincture of Cudbear (F. 419)	16 Cc.
Water, a sufficient quantity	
To make	1000 Cc.

Dissolve the Vanillin and Cumarin in the Alcohol, add the Glycerin, Syrup, and Compound Tincture of Cudbear, and, lastly, enough water to make *one thousand* (1000) *cubic centimeters*.

427. TINCTURA VIBURNI OPULI COMPOSITA. *N. F.*

Compound Tincture of Viburnum.

Viburnum Opulus	35 Gm.
Dioscorea	35 Gm.
Scullcap	10 Gm.
Cloves	50 Gm.
Cinnamon	65 Gm.
Glycerin	65 Cc.
Alcohol, Water, of each, a sufficient quantity	
To make	1000 Cc.

Reduce the drugs to a moderately coarse (No. 40) powder. Mix the Glycerin with *seven hundred and fifty* (750) *cubic centimeters* of Alcohol and moisten the powder with *one hundred and fifty* (150) *cubic centimeters* of this Mixture, and macerate for 48 hours in a percolator. Then percolate with the remainder of this menstruum, followed by a mixture of *five* (5) *volumes* of Alcohol and *one* (1) *volume* of Water, until *one thousand* (1000) *cubic centimeters* of tincture are obtained.

428. TINCTURA ZEDOARIÆ AMARA. *N. F.*

Bitter Tincture of Zedoary.

Compound Tincture of Zedoary.

Zedoary, root	250 Gm.
Aloes	125 Gm.
Rhubarb	62 Gm.
Gentian	62 Gm.
White Agaric	62 Gm.
Saffron	62 Gm.
Glycerin	125 Cc.
Alcohol, Water, of each, a sufficient quantity	
To make	1000 Cc.

Reduce the solids to a moderately coarse (No. 40) powder, moisten this with a sufficient quantity of a mixture of *two* (2) *volumes* of Alcohol and *one* (1) *volume* of Water, and percolate it in the usual manner, with this menstruum, until *seven hundred and fifty* (750) *cubic centimeters* of percolate are obtained. Add to this the Glycerin and set it aside. Then continue the percolation until the drugs are practically exhausted, evaporate the new percolate to *one hundred and twenty-five* (125) *cubic centimeters*, and add it to the reserved portion.

Each fluidrachm represents 15 *grains of Zedoary,* 7½ *grains of Aloes, and* 3¾ *grains, each, of the other drugs.*

Note.—The above preparation is not identical with the *Tinctura Zedoariæ Composita* (also known as *Tinctura Carminativa, Tinctura Wedelii*) which was formerly official in some continental Pharmacopœias.

429. TINCTURÆ ÆTHEREÆ. *N. F.*

Ethereal Tinctures.

General Formula.

The Drug, properly comminuted	125 Gm.
Alcohol, Ether (U. S. P.), of each a sufficient quantity	
To make	1000 Cc.

Percolate the Drug in the usual manner, but with proper precautions to avoid loss of menstruum by evaporation, with a mixture of *one* (1) *volume* of Ether, and *two* (2) *volumes* of Alcohol, until *one thousand* (1000) *cubic centimeters* of percolate are obtained.

Note.—This formula is to be used when Ethereal Tinctures of Belladonna, Castor, Digitalis, Lobelia, Valerian, or of other drugs, are to be prepared.

430. TROCHISCI MAGNESIÆ. *N. F.*

(U. S. P., 1880.)

Troches of Magnesia.

Magnesia	19.5	Gm.
Nutmeg, in fine powder	1	Gm.
Sugar, in fine powder	58.5	Gm.
Mucilage of Tragacanth (U. S. P.), a sufficient quantity		
To make	100	troches.

Rub the Magnesia and the powders together until they are thoroughly mixed; then with Mucilage of Tragacanth form a mass, to be divided into *one hundred* (100) *troches.*

431. TROCHISCI SODII SANTONINATIS. *N. F.*

(U. S. P., 1880.)

Troches of Sodium Santoninate.

Sodium Santoninate, in fine powder	6.5	Gm.
Sugar, in fine powder	130	Gm.
Tragacanth, in fine powder	3.75	Gm.
Orange Flower Water, a sufficient quantity		
To make	100	troches.

Rub the powders together until they are thoroughly mixed; then with Orange Flower Water form a mass, to be divided into *one hundred* (100) *troches.*

Troches of Sodium Santoninate should be kept in dark-amber-colored vials.

432. UNGUENTUM ACIDI GALLICI. *N. F.*

(U. S. P., 1880.)

Ointment of Gallic Acid.

Gallic Acid	10	Gm.
Benzoinated Lard (U. S. P.)	90	Gm.

Rub the Gallic Acid with the Benzoinated Lard, gradually added, until they are thoroughly mixed, avoiding the use of an iron spatula.

433. UNGUENTUM CALAMINÆ. *N. F.*

Calamine Ointment.

Unguentum Zinci Carbonatis (Impuri). Unguentum Calaminare. Turner's Cerate.

Prepared Calamine	16.5	Gm.
Ointment (U. S. P.)	83.5	Gm.

Mix them intimately, by trituration, so as to produce a smooth and homogeneous ointment.

434. UNGUENTUM CAMPHORÆ. *N. F.*

Camphor Ointment.

Unguentum Camphoratum.

Camphor, in coarse powder	22	Gm.
White Wax	11	Gm.
Lard	67	Gm.

Melt the White Wax and Lard with a gentle heat, then add the Camphor, and stir the Ointment until it is cold.

435. UNGUENTUM FUSCUM. *N. F.*

Brown Ointment.

Unguentum Matris. Mother's Salve.

Camphorated Brown Plaster (F. 119)	50	Gm.
Olive Oil	25	Gm.
Suet	25	Gm.

Melt them together, and stir the mass until it is cold.

436. UNGUENTUM MEZEREI. *N. F.*

(U. S. P., 1880.)

Mezereum Ointment.

Fluid Extract of Mezereum (F. 170)	25	Cc.
Lard	80	Gm.
Yellow Wax	12	Gm.

Melt together the Lard and Wax with a moderate heat, add the Fluid Extract, and stir the mixture constantly until the Alcohol has evaporated; then continue to stir until cool.

437. UNGUENTUM PICIS COMPOSITUM. *N. F.*

Compound Tar Ointment.

Oil of Tar	4	Gm.
Tincture of Benzoin (U. S. P.)	2	Cc.
Oxide of Zinc	3	Gm.
Yellow Wax	26	Gm.
Lard	32	Gm.
Cotton-Seed Oil	35	Gm.

Melt the Yellow Wax and Lard with the Cotton-Seed Oil at a gentle heat. Add the Tincture of Benzoin, and continue heating until all the Alcohol has evaporated. Then withdraw the heat, add the Oil of Tar, and finally the Oxide of Zinc, incorporating the latter thoroughly, so that, on cooling, a smooth, homogeneous ointment may result.

438. UNGUENTUM SULPHURIS ALKALINUM. *N. F.*

(U. S. P., 1880.)

Alkaline Sulphur Ointment.

Washed Sulphur	20	Gm.
Potassium Carbonate	10	Gm.
Water	5	Cc.
Benzoinated Lard (U. S. P.)	65	Gm.

Rub the Sulphur with the Potassium Carbonate and the Water, gradually add the Benzoinated Lard, and mix thoroughly.

439. UNGUENTUM SULPHURIS COMPOSITUM. *N. F.*

Compound Sulphur Ointment.

Wilkinson's Ointment. Hebra's Itch Ointment.

Precipitated Calcium Carbonate	10	Gm.
Sublimed Sulphur	15	Gm.
Oil of Cade	15	Gm.
Soft Soap (U. S. P.)	30	Gm.
Lard	30	Gm.

Mix the Lard with the Soft Soap and Oil of Cade. Then gradually incorporate the Sublimed Sulphur and Precipitated Calcium Carbonate.

440. VINUM ALBUM FORTIUS. *N. F.*

(U. S. P., 1880.)

Stronger White Wine.

White Wine	875	Gm.
Alcohol	125	Gm.

Mix them.

When tested for Alcohol, Stronger White Wine should contain not less than twenty (20) *per cent. nor more than twenty-five* (25) *per cent. of Absolute Alcohol by weight.*

441. VINUM ALOES. *N. F.*

(U. S. P., 1880.)

Wine of Aloes.

Purified Aloes (U. S. P.)	60	Gm.
Cardamom	10	Gm.
Ginger	10	Gm.
Stronger White Wine (F. 440), a sufficient quantity		
To make	1000	Cc.

Mix the Aloes, Cardamom, and Ginger, and reduce them to a moderately coarse (No. 40) powder. Macerate the powder with *nine hundred* (900) *grammes* of Stronger White Wine for seven days, with occasional agitation, and filter through paper, adding, through the filter, enough Stronger White Wine to make the filtered liquid weigh *one thousand* (1000) *grammes.*

442. VINUM AURANTII. *N. F.*

Wine of Orange.

Oil of Bitter Orange	1 Cc.
Alcohol	10 Cc.
Purified Talcum (F. 395)	15 Gm.
Sherry Wine, a sufficient quantity	
To make	1000 Cc.

Triturate the Purified Talcum, first with the Alcohol, in which the Oil of Bitter Orange had previously been dissolved, and afterwards with *seven hundred and fifty* (750) *cubic centimeters* of Sherry Wine, gradually added. Filter the mixture through a wetted filter, returning the first portions of the filtrate until it runs through clear, and, lastly, pass enough Sherry Wine through the filter to make *one thousand* (1000) *cubic centimeters*.

443. VINUM AURANTII COMPOSITUM. *N. F.*

Compound Wine of Orange.

Elixir Aurantiorum Compositum (Germ. Pharm.).
Compound Elixir of Orange.

Bitter Orange Peel	200 Gm.
Absinthium	65 Gm.
Menyanthes, leaves	65 Gm.
Cascarilla	65 Gm.
Cinnamon (Cassia)	40 Gm.
Gentian	40 Gm.
Potassium Carbonate	10 Gm.
Sherry Wine, a sufficient quantity	
To make	1000 Cc.

Reduce the six first-named drugs to a moderately coarse (No. 40) powder, mix with this the Potassium Carbonate, moisten the mixture with Sherry Wine, and let it macerate during twenty-four hours. Then pack it in a percolator, and percolate with Sherry Wine, in the usual manner, until *one thousand* (1000) *cubic centimeters* of product are obtained.

444. VINUM CARNIS. *N. F.*

Wine of Beef.

Beef and Wine.

Extract of Beef	35 Gm.
Hot Water	60 Cc.
Sherry Wine, a sufficient quantity	
To make	1000 Cc.

Pour the Hot Water upon the Extract of Beef, contained in a mortar or other suitable vessel, and triturate until a smooth mixture results. Then gradually add, while stirring, *nine hundred* (900) *cubic centimeters* of Sherry Wine. Transfer the mixture to a bottle, set this aside for a few days in a cold place, if convenient, then filter, and pass enough Sherry Wine through the filter to make *one thousand* (1000) *cubic centimeters*.

Each fluidrachm represents 2 grains of Extract of Beef.

Note.—The Extract of Beef suitable for this or similar preparations is that which is prepared by Liebig's method.

445. VINUM CARNIS ET FERRI. *N. F.*

Wine of Beef and Iron.

Beef, Wine, and Iron.

Extract of Beef	35 Gm.
Tincture of Ferric Citro-Chloride (F. 407)	35 Cc.
Hot Water	60 Cc.
Sherry Wine, a sufficient quantity	
To make	1000 Cc.

Pour the Hot Water upon the Extract of Beef, contained in a mortar or other suitable vessel, and triturate until a smooth mixture results. Then gradually add, while stirring, *eight hundred* (800) *cubic centimeters* of Sherry Wine. Next add the Tincture and enough Sherry Wine to make *one thousand* (1000) *cubic centimeters*. Transfer the mixture to a bottle, set this aside for a few days in a cold place, if convenient, filter, and pass enough Sherry Wine through the filter to restore the original volume.

Each fluidrachm represents 2 grains of Extract of Beef and 2 minims of Tincture of Ferric Citro-Chloride.

Note.—Regarding Extract of Beef, see Note to F. 444.

446. VINUM CARNIS, FERRI, ET CINCHONÆ. *N. F.*

Wine of Beef, Iron, and Cinchona.

Beef, Wine, Iron, and Cinchona.

Extract of Beef	35 Gm.
Tincture of Ferric Citro-Chloride (F. 407)	35 Cc.
Quinine Sulphate	2 Gm.
Cinchonidine Sulphate	1 Gm.
Citric Acid	0.75 Gm.
Hot Water	60 Cc.
Angelica Wine, a sufficient quantity	
To make	1000 Cc.

Dissolve the Citric Acid and the Quinine and Cinchonidine Sulphates in the Hot Water, and pour the solution upon the Extract of Beef, contained in a mortar or other suitable vessel. Triturate the liquid with the Extract until they form a smooth mixture, then gradually add, while stirring, *eight hundred* (800) *cubic centimeters* of Angelica Wine, and afterwards the Tincture of Ferric Citro-Chloride. Transfer the mixture to a bottle, set this aside for a few days in a cold place, if convenient, filter, and pass enough Angelica Wine through the filter to make *one thousand* (1000) *cubic centimeters*.

Each fluidrachm represents about 2 grains of Extract of Beef, 2 minims of Tincture of Ferric Citro-Chloride, and small quantities of Cinchona alkaloids.

Note.—Regarding Extract of Beef, see Note to F. 444. Angelica Wine is a variety of sweet California wine.

447. VINUM ERYTHROXYLI. *N. F.*

Wine of Erythroxylon.

Wine of Coca.

Fluid Extract of Coca (U. S. P.)	65 Cc.
Alcohol	65 Cc.
Sugar	65 Gm.
Claret Wine, a sufficient quantity	
To make	1000 Cc.

Dissolve the Sugar in about *six hundred* (600) *cubic centimeters* of Claret Wine, add the Alcohol and Fluid Extract, and enough Claret Wine to make *one thousand* (1000) *cubic centimeters*. Let the mixture stand a few days in a cold place, if convenient, then filter, and pass enough Claret Wine through the filter to restore the original volume.

Each fluidounce represents 30 grains of Erythroxylon (Coca).

Note.—In place of Claret Wine, any other palatable wine may be used, according to the demand or preference of the prescriber or consumer.

448. VINUM ERYTHROXYLI AROMATICUM. *N. F.*

Aromatic Wine of Erythroxylon.

Aromatic Wine of Coca.

Fluid Extract of Coca (U. S. P.)	65 Cc.
Compound Elixir of Taraxacum (F. 111)	10 Cc.
Syrup of Coffee (F. 367)	25 Cc.
Port Wine	165 Cc.
Aromatic Elixir (U. S. P.)	300 Cc.
Sherry Wine, a sufficient quantity	
To make	1000 Cc.

Mix the five first-named ingredients with *four hundred*

(400) *cubic centimeters* of Sherry Wine. Let the mixture stand several days in a cold place, if convenient, then filter, and pass enough Sherry Wine through the filter to make the product measure *one thousand* (1000) *cubic centimeters.*

Each fluidounce represents 30 *grains of Coca.*

449. VINUM FRAXINI AMERICANÆ. *N. F.*

Wine of White Ash.

Fraxinus (bark), in No. 40 powder . .	500 Gm.
Stronger White Wine (F. 440), a sufficient quantity	
To make	1000 Cc.

Moisten the powdered Fraxinus with *one thousand* (1000) *cubic centimeters* of Stronger White Wine, macerate it during three days in a well-covered vessel, then pack it in a percolator, and gradually pour on Stronger White Wine, until *one thousand* (1000) *cubic centimeters* of percolate are obtained. Keep the product in well-stoppered bottles, which should be completely filled, and stored in a cool place.

Each fluidrachm represents 30 *grains of Fraxinus* (*bark*).

450. VINUM PEPSINI. *N. F.*

Wine of Pepsin.

Pepsin (U. S. P.)	17.5 Gm.
Glycerin	50 Cc.
Hydrochloric Acid (U. S. P.) . . .	4 Cc.
Water	60 Cc.
Purified Talcum (F. 395)	16 Gm.
Stronger White Wine (F. 440), a sufficient quantity	
To make	1000 Cc.

Mix the Water, Glycerin, and Hydrochloric Acid, and agitate the Pepsin with the mixture until it is completely disintegrated and apparently dissolved. Then add enough Stronger White Wine to make *one thousand* (1000) *cubic centimeters*, mix the liquid intimately with the Purified Talcum, allow it to stand for a week, if convenient, frequently shaking, then filter, and pass enough Stronger White Wine through the filter to restore the original volume.

Each fluidrachm represents 1 *grain of Pepsin* (*U. S. P.*).

451. VINUM PICIS. *N. F.*

Wine of Tar.

Tar	100 Gm.
Water	250 Cc.
Pumice, in moderately fine powder .	125 Gm.
Stronger White Wine (F. 440), a sufficient quantity	
To make	1000 Cc.

Upon the Tar contained in a suitable vessel pour *two hundred and fifty* (250) *cubic centimeters* of cold Water, and triturate the mixture thoroughly; then pour off the Water and throw it away. Mix the remaining Tar thoroughly with the powdered Pumice, and add *one thousand* (1000) *cubic centimeters* of Stronger White Wine. Stir frequently during four hours, then transfer the mixture to a wetted filter, and, after the liquid has passed, pour on enough Stronger White White to make the filtrate measure *one thousand* (1000) *cubic centimeters.*

452. VINUM PRUNI VIRGINIANÆ. *N. F.*

Wine of Wild Cherry.

Wild Cherry, in No. 40 powder . . .	250 Gm.
Sugar	165 Gm.
Water	200 Cc.
Alcohol	75 Cc.
Purified Talcum (F. 395)	15 Gm.
Angelica Wine, a sufficient quantity	
To make	1000 Cc.

Dissolve the Sugar in the Water. Moisten the Wild Cherry with a sufficient quantity of this solution, and allow it to macerate during one hour. Then transfer it to a percolator, pour upon it the remainder of the solution, and afterwards enough Angelica Wine until *nine hundred* (900) *cubic centimeters* of percolate are obtained. Add to this the Alcohol, mix the Purified Talcum intimately with the liquid, then filter, returning the first portions of the filtrate until it runs through clear, and finally pass enough Angelica Wine through the filter to make the product measure *one thousand* (1000) *cubic centimeters.*

Each fluidrachm represents 15 *grains of Wild Cherry.*

453. VINUM PRUNI VIRGINIANÆ FERRATUM. *N. F.*

Ferrated Wine of Wild Cherry.

Tincture of Ferric Citro-Chloride (F. 407)	85 Cc.
Wine of Wild Cherry (F. 452), enough to make	1000 Cc.

Mix the Tincture with enough Wine of Wild Cherry to make *one thousand* (1000) *cubic centimeters.*

Each fluidrachm represents 5 *minims of Tincture of Ferric Citro-Chloride and* 13¾ *grains of Wild Cherry.*

454. VINUM RHEI. *N. F.*

(U. S. P., 1880.)

Wine of Rhubarb.

Rhubarb, in No. 30 powder	100 Gm.
Calamus, in No. 30 powder	10 Gm.
Stronger White Wine (F. 440), a sufficient quantity	
To make	1000 Gm.

Moisten the mixed powders with *fifty* (50) *grammes* of Stronger White Wine, pack the mixture in a conical glass percolator, and gradually pour enough Stronger White Wine upon it to make the filtered liquid weigh *one thousand* (1000) *grammes.*

PART II.

SECTION II.

DRUGS AND MEDICINES NOT OFFICIAL.*

In the present section it is proposed to consider remedies which are not recognized in the United States or British Pharmacopœias, but which, on account of their use in domestic or professional medicine, their toxic properties, their history, or the probability that they may prove in the future remedies of power, or valuable products, require notice in an encyclopedic work like the United States Dispensatory. The limit of the present volume forbids a complete description of all of these substances, but the attempt is made to give at least the information where to look for an account of almost everything used in medicine.

ABRASTOL. *Asaprol* (β-naphtol-monosulphonate of calcium), a sulphonic derivative of beta-naphtol. It has been recommended as a food preservative, and is stated to have anti-arthritic properties. Dujardin-Beaumetz affirms that it can be given in daily doses of one hundred and fifty grains (10 Gm.) without injurious effects. Dose, from eight to fifteen grains (0·5–1 Gm.).

ABROMA AUGUSTA. Linn. f. (Nat. ord. Sterculiaceæ.) A viscid white fluid found in the fleshy bark of the root of this Indian plant is said to be of great service in *dysmenorrhœa*. A half-drachm of the fresh root is given at a dose. (*Am. Journ. Med. Sci.*, July, 1873.)

ABRUS PRECATORIUS. L. *Jequirity. Kunch. Ratti.* (Nat. ord. Leguminosæ.) The seeds of this plant, which grows in India and also in Brazil, are employed in India as a standard weight, and also for criminal poisoning. They are said to be inert when taken whole into the stomach. They contain *abric acid*, $C_{12}H_{24}N_2O$, and, according to the researches of Sidney Martin (*P. J. Tr.*, Sept. 1887; *Proc. Roy. Soc.*, vol. xlvi., 1889), two proteid poisons, a paraglobulin and an albumose, which are almost identical in their physiological and toxic properties with the similar principles found in snake venom, although less powerful. According to Flexner, the toxic action of these substances also closely resembles that of the toxins produced by bacteria, the most characteristic result being focal necroses in various organs. Flexner suggests that these in turn are due to a lesion in the blood-vessel walls caused by the abrin. (*Journ. Experimental Med.*, 1897, vol. ii.) The ordinary lethal dose of abrin for animals is said to be 0·00001 Gm. per kilo of weight. (Consult *The Non-Bacillous Nature of Abrus Poisoning*, J. H. Warden and L. A. Waddel, Calcutta, 1884; Bufalini, *Ann. di Chim. e di Farm.*, No. 2, 1886; Kobert, *Wien. Med. Blätter*, Nov. 1889.) The cold infusion, one part to twenty, has been used in chronic granular *conjunctivitis;* but, according to L. de Wecker, this is much too strong, and is liable to set up violent conjunctivitis or even keratitis. *Pannus* and *trachoma* are said to have yielded to the remedy. Two drops of a solution of the fluid extract (one part to ten) may be put in the eye once or twice a day. The solution should always be freshly made. The root of the plant is official in the India Pharmacopœia as a substitute for liquorice. David Hooper obtained from the root *glycyrrhizin* in small quantity, an organic acid, and traces of an alkaloid. (*P. J. Tr.*, 1894, 937.)

ABUTILON INDICUM. The seed of this plant (*Balbij*) is recommended as a diuretic.

ACER SACCHARINUM. L. (*A. dasycarpum*, Ehrh.) (Nat. ord. Sapindaceæ.) Emil Weschcke believes that there is an alkaloid in the ordinary *white* or *silver maple*. (*Contrib. Dep. Phar. Univ. Wisc.*, 1886.)

ACERATES DECUMBENS. Decne. (*Asclepiodora decumbens*, A. Gray.) (Nat. ord. Asclepiadaceæ.) This plant, a native of New Mexico, is stated by Wm. J. Wilson to be used as a specific in snake-bite. (*Phila. Med. Times*, v. 183.)

ACETAL. $C_6H_{14}O_2$ or $CH_3CH(OEt)_2$. *Ethylidene Diethylic Ether*, a limpid liquid, sparingly soluble in water, readily soluble in alcohol, is stated to be narcotic in dose of one drachm.

* By the term official medicines, here as well as elsewhere in this work, are meant such as are embraced in the United States and British Pharmacopœias.

ACETONE. *Dimethyl-ketone* (formerly called *Pyroacetic Spirit*) (C_3H_6O or $CH_3.CO.CH_3$) is found in small amount in normal urine, in blood, etc., and in larger amount in certain pathological conditions. It is produced by the dry distillation of sugar, gum, cellulose, etc., and therefore is always contained in crude wood naphtha. Dr. E. R. Squibb has also prepared it on a large scale by passing acetic acid vapor through a rotating iron cylinder heated to from 500° to 600° C. and containing pumice stone with precipitated barium carbonate. (*Journ. Amer. Chem. Soc.*, 1895, 197.) Prepared commercially by the dry distillation of calcium acetate, it boils at 56° C., and has a peculiar ethereal odor and sharp, burning taste. Its sp. gr. is 0·7920 at 16·4° C.

Distilled with water and lime hypochlorite, it yields nearly 200 per cent. of its weight in chloroform, and is hence largely used in the manufacture of this substance, both in this country and in Germany. In the presence of an alkali, iodine converts it into iodoform, so that a trace of acetone in methyl alcohol can be detected by the iodoform formation (*Kraemer's test*).

It is used largely as a solvent for fats, resins, and camphors. It mixes in all proportions with water, alcohol, and ether. Schlagdenhauffen asserts that commercial acetone contains an alkaloidal substance. (*P. J. Tr.*, 1884, 163.) For a method of detecting acetone in urine, see *A. J. P.*, 1889, 175. See also *Proc. A. P. A.*, 1894, 281, 1897, 690; *Ephemeris*, 1895, 1653.

ACETO-ORTHO-TOLUID. $C_7H_7.NH.C_2H_3O$. This occurs in colorless needles, easily soluble in hot water, alcohol, and ether. According to E. Barbarini (*Terap. mod.*, 1892, 532), it is a powerful depressant of animal temperature and but slightly poisonous.

ACETOPHENONE. *Hypnone. Phenyl-methyl-ketone* (C_8H_8O or $C_6H_5CO.CH_3$). A colorless liquid, boiling at 200° C., having a very tenacious, persistent odor, recalling that of bitter almonds, not inflammable, not soluble in water or in glycerin, but very soluble in alcohol, ether, chloroform, benzin, and also certain oils, especially that of sweet almonds. It is made by distilling a mixture of calcium acetate and benzoate, just as acetone is made by distilling the former salt alone. Hypnone was first proposed as an hypnotic by Dujardin-Beaumetz, who affirms that it produces in the lower animals deep sleep. The more recent researches of Laborde, of Grasset, of Mairet and Combemale, however, are concordant in showing that unless in toxic dose it does not act as a certain hypnotic in the lower animals; after a fatal dose, coma, general muscular paralysis, and death from asphyxia result. Further, according to Regnier, the effect of hypnone upon nutrition is extraordinarily active, a few days' use of it notably lowering the quantity of hæmoglobin in the blood, and causing appreciable loss of weight. Somewhat similar results have been arrived at by Kamensky. The general verdict of clinicians is that it acts in man as a very uncertain hypnotic, and, according to W. H. Flint, when it is used the system rapidly becomes tolerant of it, so that the dose has to be largely increased. It would seem, therefore, that hypnone is of little practical value, although Norman claims excellent results from hypodermic injections of from five to twelve minims in *insanity* (*Journ. Ment. Sci.*, xxxiii.). Dose, from three to ten minims (0·194–0·648 C.c.), although Rey has given as much as twenty-three grains (1·5 Gm.) without producing sleep.

ACETUM. *Vinegar*, which is no longer official either in the American or British Pharmacopœias, is a sour liquid, the product of the acetous fermentation in infusions of mixed malted and unmalted grain, or in various fruit juices. Any substance which is capable of undergoing the alcohol fermentation is further liable, under the influence of a microscopic plant, *Mycoderma aceti*, and exposure to the air at a temperature between 24° C. (75° F.) and 35° C. (95° F.), to undergo further change with oxidation, which converts the alcohol into acetic acid. Practically for success there should not be more than 12 per cent. of alcohol in the original fluid. The mycoderm may exist as a pellicle formed of extremely small cells (micrococci) in contiguous rows, or finally enveloped in a glue-like mass, or it may be in the form of rod-like cells (bacilli) more or less dispersed through the fluid.

Vinegar is frequently made by the *German process*, by which the time consumed in its formation is greatly abridged. A mixture is prepared of one part of alcohol of 80 per cent., four or six parts of water, and one-thousandth of honey or extract of malt, to act as a ferment. This mixture is allowed to trickle through a mass of beech shavings, previously steeped in vinegar, and contained in a deep oaken tub, called a *vinegar generator*. The tub is furnished near the top with a wooden diaphragm perforated with numerous small holes, which are loosely filled with packthread about six inches long, prevented from slipping through by a knot at one end. The alcoholic mixture, heated to between 24° C. (75° F.) and 35° C. (95° F.), is placed on the diaphragm, and slowly percolates the beech shavings, whereby it becomes minutely divided. It is essential to the success of the process that a current of air should pass through the tub. In order to establish this current, eight equidistant holes are pierced near the bottom of the tub, forming a horizontal row, and four glass tubes are inserted vertically in the diaphragm, of sufficient length to project above and below it. The air enters by the holes below, and passes out by the tubes. Although the air is necessary for the furnishing of oxygen, acetification consisting chiefly in the oxidation of the alcohol, the beech shavings and similar articles chiefly aid in the process by affording surface upon which the mycoderms can grow. During the process the temperature rises to 37° C. (100° F.) or 40° C. (104° F.), and remains nearly stationary while the process is going on favorably. The liquid is drawn off by a discharge-pipe near the bottom, and must be passed three or four times through the tub before the acetification is completed, which generally occupies from twenty-four to thirty-six hours. According to Wimmer, pieces of charcoal, about the size of a walnut, may be substituted for the beech shavings in the process, with the effect of expediting the acetification. The charcoal must be deprived of saline matter by diluted hydrochloric acid, and afterwards washed with water.

In his *Etudes sur le Vinaigre*, published in 1862, Pasteur proposed to substitute for the German process the sowing of the mycoderm upon the surface of a mixture of wine and vinegar, or of water, alcohol (2 per cent.), and acetic acid (1 per cent.), adding alcohol daily in small quantities after about half that contained in the original liquid had been converted into acetic acid, until a vinegar of sufficient strength was produced. In 1869, Beton-

Laugier announced that he had succeeded in carrying out this method, and in 1870 he received a prize from the Société d'Encouragement de l'Industrie National. Subsequently Mr. Emanuel Wurm further elaborated this *French process* with asserted great success. For details, see *P. J. Tr.*, xi. 133.

In England, vinegar is made from the infusion of malt by the German process, which is said to have originated with Mr. Ham, of Bristol, England, as early as 1822. The fermented wort is made to fall in a shower upon a mass of fagots of birch twigs occupying the upper part of a large vat, and, after trickling down to the bottom, is pumped up repeatedly to the top, to be again allowed to fall, until the acetification is completed. This mode of oxidizing the alcohol in the fermented wort has the advantage of rendering insoluble certain glutinous and albuminous principles, which, if not removed, would cause a muddiness in the vinegar and make it liable to spoil.

In the United States, vinegar is largely made by the German method of oxidizing very diluted alcohol, and is called *spirit vinegar;* it is often prepared from cider—*cider vinegar*. The cider is placed in barrels (with their bung-holes open), which are exposed during the summer to the heat of the sun. The acetification is completed in the course of about two years. The progress of the fermentation, however, must be watched; and as soon as perfect vinegar is formed, it should be racked off into clean barrels. Without this precaution, the acetous fermentation would run into the putrefactive, and the vinegar be spoiled. Cider vinegar contains no aldehyde. It contains malic acid, and therefore yields a precipitate with lead acetate. The want of such a precipitate indicates that the alleged cider vinegar is a manufactured substitute, although a fictitious article might yield a similar precipitate.

Vinegar may be clarified, without impairing its aroma, by throwing about a tumblerful of boiling milk into from fifty to sixty gallons of the liquid, and stirring the mixture. This operation also makes red vinegar pale.

The series of changes which occur during the *acetous fermentation* is called *acetification*. During its progress there is a disengagement of heat; the liquor absorbs oxygen and becomes turbid; and filaments form, which move in various directions, until, finally, upon the completion of the fermentation, they form a pultaceous mass. The liquor now becomes transparent, its alcohol having been converted into acetic acid. The explanation of Liebig is that the alcohol, consisting of two atoms of carbon, six of hydrogen, and one of oxygen, loses two atoms of hydrogen as the first effect of oxidation, and becomes aldehyde, composed of two atoms of carbon, four of hydrogen, and one of oxygen. This, by the absorption of one atom of oxygen, becomes two atoms of carbon, four of hydrogen, and two of oxygen; that is, acetic acid (C_2H_3O,OH). Thus the conversion of alcohol into acetic acid consists in, first, the removal of two atoms of hydrogen, and afterwards the addition of one atom of oxygen. The following equation represents this change:

$$C_2H_6O + O = C_2H_4O + H_2O$$
$$C_2H_4O + O = C_2H_4O_2.$$

Aldehyde is a colorless, inflammable, ethereal liquid, having a pungent taste and smell. Its density is 0·79. It absorbs oxygen gradually, and is thus converted into acetic acid, as just stated. Its property of absorbing oxygen gives it a reducing power like that possessed by glucose. Hence it responds to Fehling's test for that substance (PART III.). It is characterized by its forming a crystalline compound with ammonia, and also with alkaline bisulphites; it is polymerized by the action of acids and some other reagents, and thus yields *Paraldehyde* ($C_2H_4O_3$), a liquid boiling at 124° C. The name aldehyde alludes to its relation to alcohol, *al*cohol *dehyd*rogenated. Its aqueous solution is decomposed by caustic potassa, with formation of *aldehyde resin*. This is a soft, light brown mass, which, heated to 100° C. (212° F.), gives off a nauseous soapy smell.

Properties. Vinegar, when good, is of an agreeable, penetrating odor, and a pleasant acid taste. According to Magnes-Lahens, wine vinegar always contains a little aldehyde. The better sorts of vinegar have a grateful aroma, probably due to the presence of an ethereal substance, perhaps acetic ether. The color of vinegar varies from pale yellow to deep red. When long kept, especially if exposed to the air, it becomes ropy, acquires an unpleasant smell, putrefies, and loses its acidity.

The essential ingredients of vinegar are acetic acid and water; but, besides these, it contains various other substances, derived from the particular vinous liquor from which it may have been prepared. Among these may be mentioned coloring matter, gum, starch, gluten, sugar, a little alcohol, and frequently malic and tartaric acids, with a minute proportion of alkaline and earthy salts. Vinegar should be devoid of lead and copper and of free sulphuric acid, as shown by its not being discolored by hydrogen sulphide, and yielding no precipitate when boiled with a solution of calcium chloride; and of such a strength that a fluidounce would require, for saturation, not less than thirty-five grains of potassium bicarbonate. After saturation it should be free from acrid taste, indicating the absence of acrid substances the taste of which may have been concealed by that of the acetic acid.

MALT VINEGAR (*Acetum Britannicum*) has a brown color, and a sp. gr. from 1·006 to 1·019. The strongest kind, called *proof vinegar*, contains from 4·6 to 5 per cent. of acetic acid. That of British manufacture usually contains sulphuric acid, which the manufacturer is allowed by law to add in a proportion not exceeding one part in a thousand. This addition was at one time thought necessary to preserve the vinegar; but if the vinegar be properly made it does not require to be thus protected.

Vinegar is "a liquid of a brown color and peculiar odor. Specific gravity 1·017 to 1·019. 445·4 grains by weight (1 fluidounce) of it require about 402 grain-measures of the volumetric solution of soda for their neutralization, corresponding to 5·41 per cent. of real acetic acid, $HC_2H_3O_2$. If ten minims of solution of chloride of barium be added to a fluidounce of the vinegar, and the precipitate, if any, be separated by filtration, a further addition of the test should give no precipitate. Sulphuretted hydrogen causes no change of color." *Br. Pharm.*, 1885.

WINE VINEGAR (*Acetum Gallicum*) is nearly one-sixth stronger than pure malt vinegar. It is of two sorts, the white and the red, according as it has been prepared from white or from red wine. *White wine vinegar* is usually preferred. *Red wine vinegar* may be deprived of its color, and rendered limpid, by being passed through animal charcoal.

DISTILLED VINEGAR (*Acetum Destillatum; Vin-*

aigre distillé, *Oxéolat simple*, Fr.; *Destillirter Essig*, G.) was official in the U. S. Pharmacopœia, 1870, and was prepared by obtaining seven pints of distillate from eight pints of vinegar placed in a glass retort, one pint left in the retort retaining the fixed impurities, salts, etc. One hundred grains should saturate not less than seven and six-tenths grains of potassium bicarbonate. It should be wholly volatilizable by heat, yield no precipitate with lead acetate or silver nitrate, nor change color upon the addition of hydrogen sulphide or ammonia. If silver be digested with it and hydrochloric acid afterwards added, no precipitate is produced.

Adulterations. The principal foreign substances which vinegar is liable to contain are sulphuric and sulphurous acids, certain acrid substances, and copper and lead, derived from improper vessels used in its manufacture. Tin has been found in it after standing a short time in tin vessels. Hydrochloric and nitric acids are but rarely present. A test said to have been discovered by Chevallier (*A. J. P.*, April, 1872) is as follows. Put an ounce of the suspected vinegar into a small porcelain capsule, over a water-bath, and evaporate to about half a drachm, or to the consistence of a thin extract. When cool, add half a fluidounce of stronger alcohol, and thoroughly triturate. The free sulphuric acid, if present, will be taken up by the alcohol to the exclusion of any sulphate. Filter the alcoholic solution, add one fluidounce of distilled water, evaporate off the alcohol, and filter. Acidulate the filtrate with hydrochloric acid, add a few drops of a solution of barium chloride, and a white precipitate of barium sulphate will result if the sample of vinegar has been adulterated with sulphuric acid. Other methods are described by O. Hehner (*Arch. der Pharmacie*, May, 1877), see *A. J. P.*, May, 1877, Nessler (*Pharm. Cent. Halle*, No. 40, 1877), *Chem. and Drug*, April 14, 1877, *The Analyst*, 1877, 163, *N. R.*, Feb. 1878, F. Masset (*Journ. de Pharm. d'Anvers*, 1879, 88), *A. J. P.*, Feb. 1880, *Drug. Circ.*, 1882, 100, *Amer. Drug.*, 1885, 147, *Archiv d. Pharm.*, 1886, 597, *Amer. Drug.*, 1892, 103, *A. J. P.*, 1899, 71.

Barium chloride is not a suitable test for the presence of free sulphuric acid, as it will cause a precipitate with sulphates, which are often found in vinegar when no free sulphuric acid is present. The evaporation of a sample of vinegar in contact with a piece of white sugar or on white paper will often show the presence of free sulphuric acid by the charring which ensues. A very simple method, discovered by A. Ashby, of detecting free mineral acids in vinegar is mentioned by Allen (*Com. Org. Analysis*, 2d ed., i 392). A solution of logwood is prepared from boiling water and fresh logwood chips. Separate drops of this solution are spotted on the surface of a flat porcelain dish and evaporated to dryness over a water-bath. To each spot a drop of the suspected sample (concentrated first if desirable) is added, and the heating continued until it has evaporated. If the vinegar be pure the residue will be found to have a bright yellow color, but in the presence of a very small proportion of mineral acid the residue assumes a red color. The acrid substances usually introduced into vinegar are red pepper, long pepper, pellitory, grains of paradise, and mustard seed. These may be detected by evaporating the vinegar to an extract, which will have an acrid, biting taste, if any one of these substances be present. By far the most dangerous impurities in vinegar are copper and lead. The former may be detected by a brownish precipitate on the addition of potassium ferrocyanide to the concentrated vinegar; the latter, by a blackish precipitate with hydrogen sulphide, and a yellow one with potassium iodide. Pure vinegar is not discolored by hydrogen sulphide. According to Chevallier, wine vinegar which has been strengthened with acetic acid from wood sometimes contains a minute proportion of arsenic, which is probably derived from arseniferous sulphuric acid, employed in preparing the acetic acid.

Medical Properties. Vinegar acts as a refrigerant and diuretic. With this view it is added to diluent drinks in inflammatory fevers. It is sometimes used against *seat-worms*, and for other purposes, as a clyster, diluted with twice or thrice its bulk of water. Externally it is employed as a fomentation in bruises and sprains; it is a very valuable remedy in *dermatitis* from exposure to the sun. Diluted with water, it forms the best means of clearing the eye from small particles of lime. Its vapor is inhaled in certain states of *angina*, and it is diffused through sick-rooms under the impression that it destroys unwholesome effluvia, though, in fact, it has no such action. The dose is from one to four fluidrachms (3·69–14·7 C.c.); as a clyster, the quantity used is one or two fluidounces (29·5–59·1 C.c.).

At one time vinegar was very much used in pharmacy as a menstruum capable of dissolving out alkaloidal and other active principles in drugs. The organic matters contained in it make it, however, liable to undergo decomposition, and although for a time this was in great measure overcome by the use of distilled vinegar, dilute acetic acid has finally been preferred by the revisers of both Pharmacopœias.

ACETYLENE. C_2H_2. The wide-spread use of acetylene for purposes of lighting, and the common fear of poisoning by it, seem to require notice of the substance in the present volume.

Acetylene was first prepared by Berthelot, who obtained it by passing the electric spark between carbon points in an atmosphere of hydrogen. It may also be prepared from ethylene by forming ethylene bromide and acting upon this with caustic potash. It is, however, now prepared on a large scale by the decomposition of carbides like calcium carbide with water according to the reaction:

$$C_2Ca + 2H_2O = C_2H_2 + Ca(OH)_2.$$

The product so obtained is almost always contaminated with phosphine, which can be removed by washing it with bromine water.

Acetylene is a colorless gas of ethereal odor, slightly soluble in water, more readily in alcohol and ether, and most abundantly in acetone. It burns ordinarily with a very smoky flame, but from a burner with a fine slit gives a clear white flame. It forms an explosive mixture with air, also a series of explosive acetylides with copper, silver, and other metals.

Acetylene appears to be practically free from poisonous properties. Rosemann (*Archiv f. Exper. Path.*, xxxvi., 1895) found that blood which had been exposed outside of the body to the point of saturation gave easily the spectroscopic lines of oxyhæmoglobin, as did also the blood of animals which had been killed by breathing acetylene vapor. He also found it necessary to use for a length of time in very large quantities acetylene in order to produce any toxic symptoms whatever.

In Moissan's experiments from 40 to 79 per cent. of the vapor was necessary in the air breathed before toxic manifestations were produced (*Compt.-Rend.*, cxxi.), whilst Oliver found that no symptoms were caused so long as even a moderate amount of atmospheric air was maintained with the vapor; and when the animal was made to breathe pure acetylene gas the symptoms were very similar to, if not identical with, those of asphyxiation. (*British Med. Journ.*, i. 1898.)

ACETYLPHENYLHYDRAZIN. C_6H_5NH, $NH.CH_3CO$. This substance, first introduced into medicine in an impure form, under the name of *pyrodin*, has since been used in an alleged pure condition under the name of *hydracetin*. It is chemically closely allied to acetanilid, differing solely in the possession of one imido-group (NH); it is, as indicated by its name, hydrazin in which the hydrogen atoms are replaced by phenyl and acetyl. It is made by heating together phenylhydrazin and glacial acetic acid, and purifying the product by recrystallization. Dr. Guttmann (*Prager Med. Wochensch.*, 1889) demonstrated that this substance is a powerful poison, seven and a half grains being sufficient to kill a rabbit, with a remarkable destruction of the red blood-cells. He found it a powerful antipyretic, in doses of from one and a half to two and a half grains, but believes it to be a very dangerous remedy on account of its action on the blood. Externally he considered it to be safe, and allied to pyrogallic acid in its influence upon *skin diseases;* but Dr. Basch (*Lancet*, 1890) has seen very violent poisoning from the use of a 10 per cent. ointment, without benefit to the *psoriasis*. On the other hand, Dr. George Lemoine (*Bull. Méd.*, 1889) finds it, in doses of three-quarters of a grain, a valuable remedy in the treatment of *hectic fever of phthisis*, reducing the temperature and checking night-sweats. When the dose of two and a half grains (0·16 Gm.) per day is exceeded, violent symptoms are apt to be produced.

ACHILLEA. *U. S.* 1870. *Herbe aux Charpentiers, Millefeuille*, Fr. *Schafgarbe, Schafrippe*, G. *Millefoglie*, It. *Cientoenrama, Yerba de San Juan*, Sp. *Achillea Millefolium*, L. *Milfoil*, or *yarrow*, is a perennial herb, very common both in Europe and America. It is from a foot to eighteen inches high, and is specifically distinguished by its doubly pinnate, downy, minutely divided leaves, with linear, dentate, mucronate divisions, from which it derived the name of milfoil, by its furrowed stem and calyx, and by its dense corymb of whitish flowers, which appear throughout the summer, from June to September. The whole herb is medicinal. *Achillea Nobilis*, L., and *A. Moschata*, Jacq., or *Iva* of Europe, are sometimes used as substitutes for *A. Millefolium*. Von Planta-Reichenau found in it a bitter, aromatic, bluish-green volatile oil, *Ivaol* ($C_{12}H_{20}O$), and a peculiar nitrogenous principle, *Moschatin* ($C_{21}H_{27}NO_7$). (*Ann. Chem. Pharm.*, clv. 145, 1870.) For further particulars, see *P. J. Tr.*, March, 1871. *Ivain*, $C_{24}H_{42}O_5$, has also been isolated; it occurs as a dark yellow resinous mass, insoluble in water, readily soluble in alcohol, and producing an intensely bitter solution.

Both the flowers and leaves of *A. Millefolium* have an agreeable, though feeble aromatic odor, which continues after drying, and a bitterish, astringent, pungent taste. The aromatic properties are strongest in the flowers, the astringency in the leaves. The plant contains besides a volatile oil and tannin a peculiar principle, *Achillein*, which was discovered by Zanon. (*Ann. Chem. Pharm.*, lviii. 21.) As analyzed by Von Planta (*Ann. Chem. Pharm.*, clv., 1870) its formula is $C_{20}H_{38}N_2O_{15}$. It occurs in a brownish-red mass of a strongly bitter taste, soluble in water, more feebly in alcohol, not at all in ether. It has been surmised to be an alkaloid, but this is very doubtful. *Achilleic acid*, also discovered by Zanon, is affirmed by Hlasiwetz to be identical with aconitic acid. The oil, which may be obtained separately by distillation with water, has a beautiful azure-blue color, and the peculiar flavor of milfoil. The active principles are extracted both by water and alcohol. *A. Millefolium* is a mild aromatic sudorific tonic and astringent, and is sometimes used in acute *suppression of the menses*, in the form of a hot infusion (℥i to Oi). Dose, from four to six ounces; the volatile oil has been used in doses of twenty or thirty drops. Pappi states that *achillein* given in divided doses up to from thirty to seventy-five grains (1·9–4·8 Gm.) causes marked irregularity of the pulse.

ACIDUM BETA-NAPHTOLINSULPHONICUM. $C_{10}H_7.SO_3H$. *Beta-naphtol sulphonic acid* occurs in white pearly scales, tinged with red. It is readily soluble in water and alcohol, and appears to be interesting to the physician only as a test for albumin in the urine. According to E. Riegler, the reaction is so delicate that it will make plainly visible the presence of one part of albumin in forty thousand of water. Albumoses and peptones are also thrown down, but such precipitates disappear on the application of heat, which does not occur with albumin. *Riegler's test* is best performed by adding to five or six cubic centimetres of the urine from twenty to thirty drops of a 5 per cent. aqueous solution of the reagent.

ACIDUM BUTYRICUM. (See *Fruit Essences.*)

ACIDUM GLYCERINO-PHOSPHORICUM. *Glycerin Phosphoric Acid.* $C_3H_5\begin{matrix}(OH)_2\\O.PO_3H_2\end{matrix}$. This is an oily liquid whose salts have been commended as powerful nerve tonics in *neurasthenia* and allied conditions. The 25 per cent. sterilized solution of the sodium salt given hypodermically, in dose of one Cm., increased to four Cm., has been especially used in *sciatica*. The iron salt has been used in *chlorosis*. (*Klin. Therap. Wochenschr.*, 1898.)

ACIDUM HYDROFLUORICUM. *Hydrofluoric Acid.* (See *Fluorides.*)

ACIDUM NAPHTYLAMINSULFONICUM. *Naphtionic Acid. Sulpho-naphtylaminic Acid*, $(C_{10}H_6(NH_2)HSO_3)$, is a white powder, soluble in about four thousand parts of cold water, which has been proposed by E. Riegler on chemical grounds as an antidote for poisoning by the nitrites and in severe *iodism*. It is eliminated through the kidneys, causing acidity of the urine, and has been recommended in the treatment of chronic *cystitis*. The dose is seven and one-quarter grains (0·5 Gm.), taken with starch in a capsule every three or four hours.

ACIDUM ORTHOAMIDOSALICYLICUM. $C_6H_3(NH_2)(OH)COOH$. This is a grayish, amorphous, almost odorless, slightly sweetish powder, insoluble in water, alcohol, and ether; which has been used by R. Neisser (*Inaug. Dissert.*, Bern, 1892) in subacute *rheumatism*, with alleged good results.

ACIDUM PHENYLO-BORICUM. *Phenyloboric Acid.* $C_6H_5.B(OH)_2$. A white powder, solu-

ble with difficulty in cold water, which was found by G. Molinari (*Chem. Centralb.*, 1892, ii. 224) to be a powerful germicide, checking putrefaction in 0·75 per cent. solution, and being very poisonous to the *cholera* and other pathogenetic bacilli. It is said to act especially well locally upon *venereal ulcers*, and to be less poisonous than carbolic acid. The fatal dose for the rabbit is fixed at twenty-three grains (1·5 Gm.).

ACIDUM PHENYLO-SALICYLICUM. $C_6H_3(OH)(C_6H_5)COOH$. A whitish powder, soluble in water with difficulty, easily soluble in alcohol, ether, and glycerin; which, according to F. Bock (*Inaug. Diss.*, Berlin, 1892), is about equivalent in germicidal properties to salicylic acid. Its salts are said to be less poisonous than those of salicylic acid.

ACOIN. *Dipara-anisyl-mono-phenetol-guanidin-chlorhydrate* has been proposed by Tralldenier (*Therap. Monatsheft*, 1899, i.) as a local anæsthetic in place of cocaine. It is alleged to be less poisonous than cocaine, but its concentrated solutions are corrosive. For subcutaneous injection a solution composed of one part of acoin, eight parts of sodium chloride, and a thousand parts of distilled water should be used. It is essential that there be no free alkali, and that the solution be kept in the dark.

ACTÆA SPICATA. *Baneberry. Herb Christopher. Radix Christophoriancæ. Racine de Saint Christophe*, Fr. *Christophswurz, Wolfswurz*, G. This is a perennial, herbaceous plant (nat. ord. Ranunculaceæ) growing in the woods of mountainous regions from Japan to Central Europe as well as in Siberia, and attaining a height of two feet or more. The root is of a dark brown color, and bears some resemblance to that of *Helleborus niger*, for which it is said to be occasionally substituted. Its odor, in the recent state, is sweetish and rather nauseous, but is in great measure dissipated by drying. The taste is bitterish and somewhat acrid. In its operation on the system, the root is purgative and sometimes emetic, and is capable, in overdoses, of producing dangerous effects. It is unknown in this country. We have, however, two native species of Actæa,—viz., *A. alba*, L. (Mill.) (*A. spicata*, var. *alba*, L.), and *A rubra*, Ait. (Willd.) (*A. spicata*, var. *rubra*, Ait.),—distinguished by the color of their berries, which in the former are white, and in the latter red. They are sometimes called *white* and *red cohosh*, a name derived from the language of the aborigines. They grow in the rich deep mould of rocky woods, from Canada to Virginia. They are said to have been much esteemed by the Indians. Their medical properties are probably similar to those of *A. spicata*. The name *baneberry*, given to different species of Actæa, was derived from the reputed poisonous properties of their berries. According to Frederick Stearns, the rhizome of *Actæa alba* is violently purgative. (*Proc. A. P. A.*, 1858.)

ACTINOMERIS HELIANTHOIDES. Nutt. *Gravel Weed. Diabetes Weed.* (Nat. ord. Compositæ.) The root is said to be largely used in Upper Georgia in *dropsy* and *chronic cystitis*. Dose of infusion (ounce to a pint), one fluidounce (31 C.c.).

ADANSONIA DIGITATA. L. *Baobab.* A tree of enormous magnitude, belonging to the Malvaceæ. It is a native of Africa, extending quite through that continent from Senegal to Abyssinia, and has been introduced into the West Indies. The leaves and bark of this tree abound in mucilage, and have little smell or taste. By the Africans the leaves are used as a diaphoretic, and the subacid pulp of the fruit in *dysentery*. Under the name of *cream-of-tartar tree* various trees whose fruit contains or has been supposed to contain cream of tartar are spoken of in books. The most important of these is the *Adansonia Gregorii* of North Australia. Another cream-of-tartar fruit is yielded by a tree of South Africa, which, according to Mr. E. M. Holmes, is probably the *Adansonia Madagascariensis*, Baillon. This fruit has been examined by E. J. Millard (*P. J. Tr.*, April, 1890), who found that it contains no cream of tartar at all. It is probably identical with a cream-of-tartar fruit examined by F. L. Slocum. (*A. J. P.*, 1880.) It is worthy of remark that Messrs. Heckel and Schlagdenhauffen (*Nouv. Rem.*, xxi. 487) have found in the fruit of the *Adansonia digitata*, or the baobab tree, as much as 2 per cent. of free tartaric acid and 12 per cent. of potassium bitartrate. Dr. Duchassaing, of Guadeloupe, West Indies, and M. Pierre, of France, commend the bark of *A. digitata* highly as an antiperiodic. (*Arch. Gén.*, 3e sér., xxiii. 535.) It is said to be acceptable to the stomach, and to produce no other observable physiological effect than increase of appetite, increased perspiration, and perhaps diminished frequency of pulse. An ounce may be boiled in a pint and a half of water to a pint, and the whole taken in a day. (*Journ. de Pharm.*, 3e sér., xiii. 412 and 421.)

ADENIA VENENATA. A climbing passion-flower of Africa, said by Schweinfurth to be used as a vesicant. (*P. J. Tr.*, March, 1874.)

ADHATODA VASICA. Nees. (Nat. ord. Acanthaceæ.) This Indian plant is asserted to contain an alkaloid, *vasicine*, in combination with *adhatodic acid*. Vasicine, isolated by Hooper, is soluble in water, sparingly in benzin and carbon disulphide, readily soluble in ether and chloroform. The claim is made for it that it exerts a powerful toxic influence upon lower forms of vegetable and animal life, and is not poisonous to the higher animals.

ADIANTUM PEDATUM. *Maidenhair. Herba Capillorum Veneris. Capillaire*, Fr. *Frauenhaar, Venushaar*, G. An indigenous fern, the bitterish and aromatic leaves of which have been used in chronic catarrhs and other pectoral affections. *A. Capillus-Veneris*, L., of Europe and this country has similar though feebler properties. It is also employed as an emmenagogue, and termed *polytrichi, polytrichon*, or *kalliphyllon*, and is given in the form of infusion, sweetened with sugar or honey; and a syrup prepared from it is popular in France, under the name of *sirop de capillaire*. The name of maidenhair has also been given to *Asplenium Trichomanes*, L., the leaves of which have a mucilaginous, sweetish, somewhat astringent taste, and have been used for the same purposes with those of the plants above mentioned. Another species of Asplenium, *A. Adiantum nigrum*, has been substituted for the genuine maidenhair; but neither of them has the aromatic flavor of that fern. In India, according to Mr. E. M. Holmes, *Adiantum lunulatum* is used as a substitute for the European maidenhair.

ADONIS VERNALIS. L. This plant belongs to the family of Ranunculaceæ, and inhabits the northern portion of Europe and Asia, in some parts of which it has long been used as an abortifacient, whilst its rhizome sometimes occurs in commercial black hellebore as an adulteration. Linderos ex-

amined the leaves and found in them 10 per cent. of *aconitic acid.* (*Liebig's Annalen d. Chem.*, N. R., 1876, 340.) Dr. Cervello, in 1882, obtained from the plant a glucoside, to which he gave the name of *adonidin.* For improved method of preparation, see *P. J. Tr.*, vol. xvi. 145, and *A. J. P.*, 1887, 609. This glucoside occurs in the form of a somewhat hygroscopic, canary-yellow powder of an intensely bitter taste; soluble in water, alcohol, and amylic alcohol; insoluble in anhydrous ether, chloroform, oil of turpentine, and benzin. Its reaction is neutral. It reduces Fehling's solution, if a few drops of hydrochloric acid have been added before heating. It exists in small quantities in all portions of the plant. For further details as to reaction, see *P. J. Tr.*, xv. 145. Podwyssotzki found commercial samples of adonidin to be mixtures of the active principle with other constituents of the plant. He gives the name of *picroadonidin* to the active principle, which he describes as an amorphous glucoside having an excessively bitter taste, possessing the properties of a cardiac poison in the highest degree, and being easily soluble in water and alcohol and entirely soluble in ether. (*P. J. Tr.*, xix., 1888, 346.) According to Cervello (*Archiv f. Exper. Path. und Pharm.*, xv.), adonidin exists also in the *Adonis cupaniana* of Southern Europe, and F. Borgiotti affirms the value of *A. æstivalis* in heart affections. (*Deutsch. Med. Zeit.*, Aug. 1888.) Tahara asserts that the glucoside of *Adonis autumnalis* is distinct, and calls it *adonine* ($C_{24}H_{40}O_9$) (*Ber. d. Chem. Gesell.*, xxiv.), whilst Dr. Y. Inoko (*Arch. Exper. Path. u. Pharm.*, xxviii.) affirms that the glucoside of *A. amurensis* of Japan is also peculiar, and assigns to it the formula $C_{20}H_{40}O_9$, allied to adonidin, but much less powerful.

Merck has described an additional crystalline principle, which fuses at 102° C., is very soluble in water and warm alcohol, and crystallizes in clear needle-like prisms. It has a neutral reaction, does not reduce Fehling's solution, and is not colored brown by alkalies. Its analysis seems to indicate a formula $C_5H_{12}O_5$, and Merck considers that it is a hitherto undescribed pentatomic alcohol, and calls it *adonite.* Whether it be identical with the *adonidulcite* announced in a preliminary communication by Podwyssotzki shortly before his death, Merck is not able to state, as no details of fusing point, formula, or chemical reactions were given by the former. (*Merck's Bulletin*, Jan. 1893.) E. Fischer (*Ber. Chem. Ges.*, 1893, 633) confirms the formula $C_5H_{12}O_5$ given by Merck, as well as the statement that it is a pentatomic alcohol; by oxidation with sodium hypobromite it is changed into *ribose*, $C_5H_{10}O_5$, which treated with sodium amalgam again yields adonite.

According to Dr. Cervello and Dr. H. A. Hare, adonidin at first slows the action of the frog's heart, increasing at the same time the force of the systole, and finally produces arrest. Dr. Hare states that this arrest is diastolic; Dr. Cervello, that it is systolic. Both experimenters found that in mammals adonidin increases very markedly the arterial pressure whilst decreasing the pulse-rate, and that after toxic doses the primary rise is followed by a marked fall of arterial pressure, with irregularity of the heart's action. The primary rise of the pressure appears to be chiefly cardiac, although there is some reason for supposing that the drug does exert some influence upon the vaso-motor system. The first slowing of the pulse was found by Dr. Hare to be due to stimulation of the inhibitory nerves, as it was prevented by their previous section, whilst finally the fall of pressure was at least in great part owing to the vaso-motor palsy. In 1879 the *Adonis vernalis* was introduced to the medical world as a cardiac stimulant by Bubnow, a pupil of Prof. Botkin. Since then it has been tested by a number of physicians with fairly concordant results. The general testimony is that its action in disease resembles that of digitalis, and that it is useful in the same class of cases. It is much more prompt than digitalis, and it is affirmed by Durand to have no cumulative tendency. There have been some differences of opinion in regard to its diuretic action. Any such influence that it may have must be attributed to the effect upon the circulation in the kidneys rather than to any marked direct power over the secreting structure. Durand asserts that it never produces disturbances of the alimentary canal, but Lublinski and Huchard have both seen it cause so much vomiting or diarrhœa as to require its withdrawal. In a case reported by Durand, in which by mistake three grains of adonidin were given every half-hour, violent vomiting and diarrhœa were the most troublesome symptoms. Bubnow employed the infusion made from the whole herb, from 4 to 8 parts in 180 parts of water, and of this he administered a tablespoonful every two hours. Durand put the dose of adonidin as two centigrammes (one-third of a grain) repeated at intervals of three or four hours.

ÆSCULUS HIPPOCASTANUM. L. *Horse-chestnut. Cortex Hippocastani. Cortex Castaneæ Equinæ. Ecorce de Marronnier (Châtaignier) d'Inde*, Fr. *Rosskastanienrinde*, G. (Nat. ord. Hippocastanaceæ.) The horsechestnut is a native of Asia, and was introduced about the middle of the sixteenth century into Europe. Quercitrin has been found by Rochleder in very small proportion in the leaves. (*Journ. de Pharm.*, Mai, 1859, 393.) *Fraxin*, a peculiar principle of the bark of *Fraxinus excelsior*, has been detected also, by Mr. Stokes, in the bark of the horsechestnut; and Rochleder has discovered in the capsules of the fruit a peculiar acid, which he names *capsulæsic acid.* (*Ibid.*, Août, 1860, 151.) The fruit and bark have been used in medicine. The *fruit* abounds in starch, but has a rough, disagreeable, bitter taste, of which it may in great measure be deprived by maceration in an alkaline solution. The starch has been prepared in France for use, the nut being reduced to pulp, washed, and treated like the potato. (*Am. Journ. of Sci. and Arts*, Sept. 1856, 264.) The bitter principle is denominated *esculin*, and, according to Rochleder, may be obtained by precipitating with lead acetate a decoction of the rind, then filtering, treating the filtered liquor with hydrogen sulphide and again filtering, evaporating to the consistence of syrup, and setting the residue aside in a cool place. In a few days the liquid is converted into a mass of crystals, which are to be expressed, and purified by repeated crystallization from alcohol, and afterwards from boiling water. If now washed on a filter with cold water till they have lost one-third of their weight, they are rendered as pure as it is possible to obtain them. For another process of preparing it, see *A. J. P.*, xliv. 400. Esculin is in shining white, prismatic crystals, inodorous, bitter, but slightly soluble in cold water, more soluble in boiling water, and very readily so in boiling alcohol and in alkaline solutions. Its solution is precipitated by lead subacetate, and its formula, according to Schiff, is $C_{15}H_{16}O_9$. When treated

with dilute sulphuric acid, it is converted into grape sugar and a substance called *esculetin*, $C_9H_6O_4$, which is now known to be a *dioxycoumarin*, $C_6H_2(OH)_2<\begin{matrix}O-CO\\CH=CH\end{matrix}$. Tannin is found in all parts of the tree, including the *leaves* as well as the bark and fruit. According to Rochleder, when pure, it is white and soluble in water, alcohol, and ether; becomes red by the absorption of oxygen; colors ferric salts *green*, but *violet* on the addition of a little alkali; precipitates gelatin but not tartar emetic; in concentrated solution is precipitated, at least partially, by sulphuric, hydrochloric, and metaphosphoric acids, while acetic acid is opposed to this result; and forms also, with potassium and sodium sulphites and ammonium sulphide, precipitates which are readily dissolved by dilute acetic acid. (*Journ. de Pharm.*, Janv. 1868, 72.) The powdered kernel of the nut is a sternutatory. The extract of the wood is said to be used in dyeing silk black. The fixed oil, extracted from the kernels by ether, has been employed in France as a topical remedy in *rheumatism;* and the bark as an antiperiodic in doses of half an ounce in the twenty-four hours, given in the form of decoction. In the United States a decoction of the leaves is popularly employed for *whooping-cough*, and to the seeds themselves, when "carried in the pocket of the patient," is attributed the marvellous property of curing *hemorrhoids*. Esculin has also been successfully administered in *malarial disorders*, in fifteen-grain (0·97 Gm.) doses repeated once during the intermissions. (*Ann. de Thérap.*, 1859, 1860.)

The fruit of the *Æsculus Pavia*, or the *Red Buckeye* of the Southern United States, is said to be an active convulsant. Mr. E. C. Batchelor (*A. J. P.*, xlv. 144) found in the cotyledons of the seeds about 2½ per cent. of a peculiar glucoside. *Æsculus glabra*, the *Ohio Buckeye*, is asserted to be useful in *portal congestion*. (*New Preparations*, ii. 21.)

ÆTHUSA CYNAPIUM. L. Poisonous properties are alternately attributed and denied to this British plant. (See *P. J. Tr.*, 1874, 202; Nov. 1880, 438.)

AGARIC. *Touchwood. Spunk. Tinder. Fungus laricis. Purging Agaric. Agaric blanc, Agaric purgatif*, Fr. *Larchenschwamm*, G. The term Agaric is more properly applied to the fungi of the genus Agaricus. The name *white agaric* or *agaricus albus* is referred, however, to *Polyporus officinalis*, Fries (*Boletus laricis*, Jacquin; *B. purgans*, Persoon), which is found upon the old trunks of the European larch and upon *Larix sibirica*, Ledebour, of Asia, and is the *white agaric* or *purging agaric* of medical writers. It is of various sizes, from that of the fist to that of a child's head, or even larger, hard and spongy, externally brownish or reddish; but, as found in commerce, it is deprived of its exterior coat, and consists of a light, white, spongy, somewhat farinaceous, friable mass, which, though capable of being rubbed into powder upon a sieve, is not easily pulverized in the ordinary mode, as it flattens under the pestle. That which is most esteemed is said to be brought from Siberia; but it is probably produced wherever the European larch grows. Dr. Wm. M. McPheeters (*St. Louis Med. and Surg. Journ.*, x. 421) found a specimen brought from the Rocky Mountains decidedly cathartic in doses of twenty-five grains. An agaric growing on the *Larix leptolepis*, and used in Japan as a sacred medicine under the name of *Toboshi* or *Eburiko*, has been found by Dr. Y. Inoko to contain agaric acid. (*Sei-I-Kwai*, April, 1891.) Agaric has a sweetish very bitter taste. *Agaric acid*, as described by Hofmeister, has the formula $C_{14}H_{27}(OH)<\begin{matrix}COOH\\COOH\end{matrix}+H_2O$. The pure acid forms a white, silky, lustrous powder, only slightly soluble in cold water, but moderately soluble in hot water. From this hot solution the acid separates out on cooling in a finely crystalline state. It fuses at 138° C. According to J. Schmieder, agaric contains a small amount of a soft resin, $C_{15}H_{20}O_4$, extracted with petroleum ether, and from 4 to 6 per cent. of a fatty body, which is made up of (1) *agaricol*, $C_{10}H_{16}O$, fusing at 223° C.; (2) *phytosterin* $C_{26}H_{44}O$; (3) solid hydrocarbons, $C_{22}H_{46}$ and $C_{29}H_{54}$; (4) *cetyl alcohol*, $C_{16}H_{33}\cdot OH$; (5) a liquid aromatic alcohol, $C_9H_{18}O$; (6) a fatty acid, $C_{14}H_{24}O_2$; and (7) *ricinoleic acid*, $C_{18}H_{34}O_3$. (Schmidt, *Lehrbuch der Pharm. Chem.*, ii., 3te Auf., 1528.)

Medical Properties. The physiological properties of agaric are not well known. In overdose it is said to cause purging. Under the name of *agaricin* an impure alcoholic extract of agaric has been much used, in doses of from one to three grains (0·065–0·195 Gm.) three times a day, against *colliquative sweats*. It is certainly a valuable remedy, free from danger, and effective, although it has some tendency to produce purging. *Agaric* or *agaricinic acid* was found by Hofmeister to act upon the lower animals as an anhidrotic, and unless in enormous doses to have little other influence except as an irritant to the gastro-intestinal canal. Doses of from one-sixteenth to one-third of a grain (0·004–0·02 Gm.) were well borne by phthisical patients, and promptly controlled the *night-sweats*. (*Arch. Exper. Pharm.*, xxv.) Köhler, Combemale, Klemperer, and other clinicians have confirmed these results, and it would seem that the acid is one of the most certain remedies of its class, and may be used almost indefinitely without affecting the general system. Dose, from one-third to three-quarters of a grain (0·02-0·05 Gm.), given in pill three times a day. A tincture of the agaric of the Canadian larch has been used successfully in *rheumatism* by Dr. J. A. Grant. (*British-Am. Journ.*, April, 1862.) For study of the precipitate found in tincture of *Boletus laricis*, see *Proc. A. P. A.*, 1889, 194.

Thoerner obtained from *Agaricus atramentosus* crystalline, dark-brown scales, which he believed to be *dioxykinon*. (*Ber. Deutsch. Chem. Ges.*, 1878, 533.) According to T. L. Phipson, *Agaricus ruber* contains a rose-red coloring matter, *ruberin*, which appears bright blue by transmitted light; being soluble in water, it is washed out of the head of the fungus by a heavy fall of rain. Ether extracts from the fungus a yellowish-white alkaloid, *agarythrine*, which has a bitter, afterwards burning taste, somewhat like aconitine; its chloride is soluble, but the sulphate insoluble in water, the latter dissolving in alcohol; it dissolves in nitric acid with red color, and is colored red by chlorinated lime and afterwards bleached. On agitating the solution of the alkaloid with ether, it is oxidized by the air to a red coloring matter, which is probably the cause of the red color of the surface of the fungus. (*Chem. News*, 1882, 199.)

Fungus chirurgor. Boletus chirurgorum, Wund-

schwamm, G. *Surgeon's agaric* is the product of *Polyporus fomentarius*, Fries, which is found upon the oak- and beech-trees of Europe. It is shaped somewhat like the horse's hoof, with a diameter of from six to ten inches. It is soft like velvet when young, but afterwards becomes hard and ligneous. It usually rests immediately upon the bark of the tree, without any supporting footstalk. On the upper surface it is smooth, but marked with circular ridges of different colors, more or less brown or blackish; on the under, it is whitish or yellowish, and full of small pores; internally it is fibrous, tough, and of a tawny-brown color. It is composed of short tubular fibres compactly arranged in layers, one of which is added every year. The best is that which grows on the oak, and the season for collecting it is August or September. It has neither taste nor smell. Among its constituents, according to Bouillon-Lagrange, are extractive, resin in very small proportion, nitrogenous matter also in small quantity, potassium chloride, and calcium sulphate; and in its ashes are found iron, and calcium and magnesium phosphate. It is prepared for use by removing the exterior rind or bark, cutting the inner part into thin slices, and beating these with a hammer until they become soft, pliable, and easily torn by the fingers. In this state it was formerly much used by surgeons for arresting *hemorrhage*, being applied with pressure. *P. igniarius*, Fries, and *P. marginatus*, Fries, yield similar products.

When prepared polyporus (so-called agaric) is steeped in a solution of nitre, and afterwards dried, it constitutes *spunk*, or *tinder*, the *amadou* of the French, which occurs in flat pieces, of a consistence somewhat like that of very soft, rotten buckskin leather, of a brownish-yellow color, capable of absorbing liquids, and inflammable by the slightest spark. It is said to be prepared also from various other species of *Polyporus*, as *P. ungulatus*, *P. fomentarius*, *P. ribis*, etc.

AGATHIN. $C_6H_4(OH).CH{=}N.N(CH_3).C_6H_5$. *Salicyl-a-methyl-phenyl-hydrazone.* This is obtained by the reaction of salicylic aldehyde upon *a*-methyl-phenyl-hydrazin. It is a colorless or greenish-white crystalline substance, without odor or taste, is insoluble in water, soluble in alcohol and ether, and melts at 74° C. It was proposed as a remedy by Dr. Israel Roos, and is said by Dr. E. Rosenbaum to act like salicylic acid. Although excellent results (see *Deutsch. Med. Zeit.*, 1892, Nos. 50, 93) have been claimed for it in *neuralgia* and *rheumatism*, without unpleasant effects other than headache, in trials by Dr. H. C. Wood it did not seem serviceable. Dose, from eight to ten grains (0·52–0.65 Gm.).

AGAVE AMERICANA. L. *American Agave. American Aloe. Maguey.* (Nat. ord. Amaryllidaceæ.) An evergreen succulent plant, indigenous in Florida, Mexico, and other parts of tropical America, and largely cultivated chiefly for hedges, in the south of Europe, especially in Spain. This and other species of Agave bear a considerable resemblance, in appearance, to the plants of the genus Aloe. From the root and leaves of the American agave, when cut, a saccharine juice flows out, which may be converted by evaporation into syrup and even sugar, and by fermentation into a vinous liquor. The saccharine principle has been extracted and is known as *agavose*. Its formula is $C_{12}H_{22}O_{11}$, and it is an optically inactive reducing sugar. According to M. Lenoble, this juice when fresh has an herbaceous somewhat nauseous odor and acrid taste, and reddens litmus paper. It is said to be laxative, diuretic, and emmenagogue, and in doses of two fluidounces, three times a day, has been found very useful in *scurvy*. (Dr. G. Perin, U.S.A., *N. Y. Journ. of Med.*, N. S., vii. 181.) According to M. Bazire, however, it is not the *A. Americana* which produces the sweet juice from which the intoxicating *pulque* of the Mexicans is obtained, but another species, bearing considerable resemblance to the Americana. The latter plant, he informs us, yields a very bitter, viscid, and astringent juice, while it is from the *Agave pulque* that the sweet fermentable juice is procured. (*Journ. de Pharm.*, 4e sér., iv. 103–4.) The expressed juice, evaporated to the consistence of a soft extract, forms a lather with water, and is employed as a substitute for soap. The fibres of the old leaves, separated by bruising and maceration in water, are used in the manufacture of rope, twine, paper, etc. The leaves are employed as a counter-irritant; in them M. Lenoble found an acrid volatile oil, a gum-resinous principle, lignin, salts of potassa and lime, and silica; and thinks that a vinegar or ointment of the leaves might be advantageously used as an epispastic. (*Journ. de Pharm. et de Chim.*, xv. 350.) It is said that a gum exudes and hardens on the leaves of the Maguey, which has been compared to gum arabic, but in fact differs from it in containing a much larger proportion of lime, and in being only partially soluble in water; the soluble portions resembling pure gum, but the larger insoluble portions having all the characteristics of bassorin. (*Ibid.*, 4e sér., iv. 104.) *Agave Virginica*, which grows in our Southern States, and is known in South Carolina by the name of *rattlesnake's master*, has a very bitter root, which is used, in the form of tincture, in *colic*. (Robert King Reid, *Inaug. Thes.*, 1849.)

AGERATUM CONYZOIDES, a Brazilian plant (nat. ord. Compositæ) said by Mr. Barker Smith (*Chem. and Drug.*, May 15, 1876) to be used as an emmenagogue.

AGOPYRIN. This is said to be a mixture of salicin, ammonium chloride, and cinchonine sulphate. It has been exploited as an antipyretic.

AGRIMONIA EUPATORIA. L. *Common Agrimony. Herba Agrimoniæ. Aigremoine, Eupatoire des Grecs*, Fr. *Odermennig, Leberklette*, G. (Nat. ord. Rosaceæ.) This species of agrimony is a perennial herb, inhabiting Asia, Europe, and North America, and, in this country, found in fields and on the borders of woods, and flowering during the summer months. Its stem, which rises from one to three feet in height, is hairy, furnished with interruptedly pinnate leaves, and terminated by a long simple spike of yellow flowers. Both the herb and root have been employed. The former has a weak but agreeable aromatic odor, and a rough, bitterish, somewhat aromatic taste. The fragrance is strongest in the flowers. The root has similar properties; but its taste is more bitter and astringent. A volatile oil may be obtained from the plant by distillation. Agrimony is a mild astringent, given in doses of a drachm (3·8 Gm.) or more. For further therapeutic details, see 16th ed. *U. S. D.*)

AILANTUS GLANDULOSA. Desf. *Ailanthus. Tree of Heaven. Chinese Sumach. Götterbaum*, G. This well-known shade-tree, belonging to the nat. ord. of Simarubaceæ, in its general aspect and the character of its foliage appears like a gigantic sumach, and was at one time considered to be a

Rhus. In France it is cultivated for the sake of its leaves, upon which the Chinese silk-worm is fed, and is known by the name of *Japan varnish* (*vernis du Japon*), from its having been mistaken for the true Japan varnish tree, which is a species of Sumach. (*P. J. Tr.*, vii. 370.) According to Prof. Hetet, the bark is an active vermifuge. When in powder it is of a greenish-yellow color, a strong, narcotic, nauseating odor, in its recent state, and of a strongly bitter taste. When chewed, besides the bitterness, it appears, through its influence on the gustatory nerves, to produce in a few moments a general uneasiness, a sense of increasing weakness, dazzling, cold sweats, with shivering and nauseous sensations, which are very remarkable, but seem to be well attested. The inference from these effects is that it has probably a powerful depressing agency on the nervous system, similar to that of tobacco. Examined chemically, the bark has been found to contain lignin, chlorophyll, a yellow coloring principle, a gelatinous substance (pectin), a bitter substance, an odorous resin, traces of a volatile oil, a nitrogenous fatty matter, and several salts. Mr. F. H. Davis examined the bark chemically, but, whilst finding traces of a crystallizable organic acid, failed to detect an alkaloid or glucoside. (*A. J. P.*, 1885, 600.) By the action of alcohol, there is obtained from the bark an *oleoresin* which has the consistence of tar, a very dark greenish-brown color, and in a high degree the smell and taste of the bark. M. Hetet experimented upon dogs with the powdered bark, powdered leaves, and various preparations of the bark. As a general result, they were found to produce a purgative effect, with copious stools and the discharge of worms. The resin purged, but rarely acted as an anthelmintic. The depressing effects on the nervous system in man were found to depend on the volatile oil, as the resin alone had no such influence. The oil is so powerful that persons exposed to the vapors. in preparing the extract, are liable to be seized with vertigo, cold sweats, and vomiting. The powdered bark has been given in several cases of *tape-worm* in the human subject, and proved remarkably successful in causing its expulsion, at the same time operating on the bowels. Dose, from seven to thirty grains (0·460–1·95 Gm.). The oleoresin produced the same effect in a somewhat smaller dose, and has the advantage that it keeps better than the bark, which loses its powers with age. A fact worthy of remark is that neither the bark nor its preparations, taken internally, produce vomiting in man; while this effect is determined by the inhalation of its vapors, when it is boiled. The cathartic operation is not violent. (*Journ. de Pharm.*, Mars, 1859, 163.) In China the bark is very popular as a remedy in *dysenteric* and other *bowel complaints*. (*A. J. P.*, 1874, 276; *P. J. Tr.*, vii. 372.)

In India the bark of the *Ailantus excelsa* is used as a bitter tonic. It is said to occur in rough, dirty-green pieces, originally large, but of so friable a character that in handling they become very much broken up. Mr. Narayan Daji found in it a peculiar bitter uncrystallizable principle and a bitter nitrogenous acid, *Ailantic Acid*, to which he attributes medical virtues. (*P. J. Tr.*, Aug. 1870, Oct. 1876, June, 1877.)

AIROL. *Bismuth Oxyiodogallate.* $C_6H_2(OH)_3COO(BiOHI)$. Under this name Lüdy has described a grayish-green, tasteless, and odorless powder which is a basic combination of bismuth, oxygen, and iodine, containing 44·5 parts of Bi_2O_3 to 24·8 parts of I.

Airol has been satisfactorily used by Socin, of Basel, as a substitute for iodoform in over two thousand surgical cases; also with alleged excellent results in *burns*, *ulcers*, *chancres*, *skin diseases*, *cold abscess*, and *fissures* by various surgeons, and has been elaborately investigated by Carl S. Haegler (Bruns, *Beiträge z. Klin. Chir.*, xv., 1896), who finds that in its antiseptic influence it is at least as active as iodoform. It produces no pain or irritation, and is said rapidly to dry the surface of a wound or ulcer. It is claimed for it that it is not only free from the objectionable odor of that drug, but is much less poisonous, Haegler having himself taken internally in the course of three days fifteen grains of the airol without the production of any disagreeable symptoms. Injected into the peritoneal cavities of the lower animals in the dose of from one to two grammes per kilo, it causes clonic convulsions, with coma, nephritis, and fatty degeneration of the liver. Airol is insoluble in ordinary menstruum, but may be dissolved in a solution of soda or in diluted mineral acids, and, like iodoform, can be used for the production of antiseptic gauze or other dressings. It may be used as a powder or as a 10 to 20 per cent. salve, which should be prepared with lard or vaseline free from water, since with water airol undergoes rapid decomposition. The 10 per cent. glycerin solution has been much employed for *tubercular* and other abscesses. It has been used in the form of suppositories made with cacao butter, with alleged excellent results, in *metritis*, *vaginitis*, *rhinitis*, etc., and its emulsion has been injected into *cold abscesses*.

Nemmer has recorded a case in which symptoms of bismuth poisoning followed the injection into the cavity of an abscess of nine and a half fluidrachms (36 Gm.) of a 10 per cent. glycerin solution.

AJUGA CHAMÆPYTIS. (*A. Chamæpithys*, L.) *Ground Pine. Chamæpitys. Ivette*, Fr. *Günsel, Feldcypresse*, G. A low, creeping, annual, labiate plant, a native of Southern Europe and the Orient. The leaves have a strong, peculiar, resinous, not disagreeable odor, and a bitter, balsamic taste. They contain a small proportion of volatile oil, and are said to be stimulant, diuretic, and aperient. They have been given in *rheumatism*, *gout*, *palsy*, and *amenorrhœa*; dose, from one to two drachms (3·88–7·77 Gm.).

Ajuga reptans, *mountain bugle* or *common bugle*, and *A. pyramidalis*, perennial plants of Europe (the former locally naturalized in fields from Canada to Southern New York), have also been used in medicine. Their virtues are probably those of a mild astringent and tonic.

AKAZGA. *Boundou. Quai. Ikaga. Icaya.* An ordeal poison, largely used in a district on the west coast of Africa, extending far into the interior, north and south of the equator. It occurs in bundles consisting usually of long, slender, crooked stems, with the root generally attached, sometimes of the branches, but seldom of the whole plant. This is about six feet high, with a yellowish-orange bark, in some parts light red, and covered by a gray efflorescence. The leaves are opposite, oval-acuminate, with a linear prolongation at the end more than an inch long. The precise botanical character of the plant is unknown, but it is thought to belong to one of the Loganiacea. Thomas R. Fraser found in the

plant an alkaloid, *akazgine*. It is colorless, crystallizable with difficulty, soluble in 60 parts of cold absolute alcohol, 16 parts of official alcohol, 180 parts of anhydrous ether, and 13,000 parts of water at 15·5° C. (60° F.). It is freely soluble in chloroform, carbon disulphide, benzene, and ether of sp. gr. 0·735. The alcoholic extract or the alkaloid acts on the system similarly to nux vomica. (*Chem. News*, Oct. 18, 1867, 203; see also *A. J. P.*, March, 1867.)

ALANGINE. This alkaloid, according to Scheriff, occurs in the bark of the stem and root of *Alangium Lamarckii*, Thwaites. It is very bitter and not crystallizable; soluble in alcohol, chloroform, and acetic ether, but insoluble in water. In small doses it has been used as a febrifuge; in doses of fifty grains (3 Gm.) it is strongly emetic.

ALCHEMILLA VULGARIS. L. *Ladies' Mantle.* (Nat. ord. Rosaceæ.) This astringent, bitterish perennial European herb was formerly employed in *diarrhœa*. By the ancients it was highly esteemed; extraordinary powers were ascribed to it by the alchemists. (See also *P. J. Tr.*, 1885, 791.)

ALCOHOL AMYLICUM. *Amylic Alcohol*, $C_5H_{11}HO$; 88. *Fusel Oil. Hydrated Oxide of Amyl. Amylic Alcohol. Grain Oil. Potato Spirit Oil. Alcool Amylique, Huile de Grain*, Fr. *Amylalcohol, Fuselöl*, G. *Fousel Oil. Hydrate of Amyl.* This oil is always present in the products of alcoholic fermentation, and, according to the experiments of L. Perdrix (*Journ. Chem. Soc.*, 1892, 90), the bacillus *B. amylozymicus* produces a fermentation in starch resulting in the large production of amyl alcohol. It is an ingredient in the ardent spirit obtained from various grains, but is most abundant in that procured from fermented potatoes. In grain spirit it is present in the proportion of about one part in five hundred by measure. When grain or potato whiskey is distilled for the purpose of obtaining alcohol, the pure spirit will continue to come over for a certain time, after which, if the distillation be continued, a milky liquid will be obtained, which, upon standing, will be covered with a stratum of this peculiar oil. Subjected to distillation, the milky liquid will at first boil at a comparatively low temperature, and yield water and a little of the oil; but after a time the boiling point will rise to 132° C. (269° F.), when the oil will come over pure, and by changing the receiver may be so collected.

Properties. Amylic alcohol is an oily, colorless liquid, of a strong, offensive odor, and an acrid, burning taste. As usually prepared it has a pale yellow color. Its sp. gr. is 0·818; that of its vapor 3·15. It boils at 132° C. (269° F.), and congeals at —25° C. (—13° F.) in the form of crystalline leaves. It is very sparingly soluble in water, but unites in all proportions with alcohol, ether, and essential oils. It dissolves iodine, sulphur, and phosphorus, and is a good solvent for fats, resins, and camphor. When dropped upon paper it does not leave a permanent greasy stain. It does not take fire like alcohol by the contact of flame, but requires to be heated to a temperature of about 54·5° C. (130° F.) before it begins to burn. Pasteur first observed that the ordinary amyl alcohol of fermentation was a mixture of two distinct alcohols, one present in smaller amount, optically active, lævogyrate, and the other, the main portion, optically inactive. Their boiling points are very close, but they may be separated by the difference in solubility of the barium amyl-sulphates, and yield different sets of derivatives. (*Compt.-Rend.*, 41, 296.) Amyl alcohol consists of five atoms of carbon 60, twelve of hydrogen 12, and one of oxygen 16 = 88. It is recognized as the hydrate of the radical amyl (C_5H_{11}), and its formula is, therefore, $C_5H_{11}OH$. Heated with phosphoric oxide, it loses a molecule of water, and forms a hydrocarbon, C_5H_{10}, homologous with ethylene, called *amylene* or *valerene*, which has been proposed as an anæsthetic. According to Long and Linebarger, American fusel oil consists chiefly of active and inactive amyl alcohol, with some isobutyl alcohol, isopropyl and ethyl alcohols, and traces of normal propyl and normal butyl alcohols. (*Chem. News*, lxi. 185–187.) Amyl alcohol should not affect the color of litmus paper, previously moistened with water, should leave no fixed residue upon evaporation, should require to dissolve it about 40 parts of distilled water at 15° C. (59° F.), and should become not more than slightly turbid upon mixture with benzin (absence of more than a little alcohol, or water). (See *Amylene* in PART II.) When subjected to oxidizing agents, it loses two atoms of hydrogen and gains one of oxygen, and becomes $C_5H_{10}O_2$, or *amylic acid*, which is identical with *valerianic acid*, the acid found in valerian. Hence the test given in the Br. Pharmacopœia of 1885: "exposed to the air in contact with platinum-black, it is slowly oxidized, yielding valerianic acid." This acid bears the same relation to amylic alcohol that acetic acid does to ethylic alcohol, and formic acid to methylic alcohol. The free amyl, $(C_5H_{11})_2$, has been isolated by E. Frankland. It is a colorless pellucid liquid, of the sp. gr. 0·7704. (*Chem. Gaz.*, March 15, 1850.) Its hydride, $C_5H_{11}H$, was discovered to be an energetic anæsthetic by Simpson, of Edinburgh.

Crude fusel oil may be obtained from the alcohol distillers. Mr. Kent, of New York, found in it, as impurities, water, alcohol, acetic and amylic acids, oxide of iron, and an amyl compound analogous to œnanthic ether. According to Messrs. T. and H. Smith, the crude oil is a mixture of propylic, butylic, and amylic alcohols, and of other alcohols much higher in the series. Fusel oil is now used largely by the manufacturers of alkaloids as a solvent and in the preparation of amyl acetate (pear oil), which is used in the manufacture of pyroxylin varnishes and smokeless powder.

Fusel oil was made official by the Dublin College in 1850, as an artificial source of valerianic acid. It was introduced in the U. S. Pharmacopœia for a similar purpose, but has finally been dismissed from both the U. S. and the Br. Pharmacopœias.

Amylic alcohol is an active poison, producing, according to the experiments of Richardson, general muscular relaxation, with violent paroxysms of convulsive tremblings. Several cases of poisoning by it have been reported. (*Lancet*, Dec. 1889; *La Normandie Méd.*, Dec. 1889.) The general symptoms are headache, giddiness, double vision, staggering, unconsciousness, fall of temperature, abolition of reflexes, muscular rigidity, followed by complete relaxation, pronounced cyanosis, and a peculiar odor from the breath suggesting that of a Jargonelle pear.

ALCORNOQUE. For an account of this bark, which has long since fallen into entire neglect, see 16th edition *U. S. D.*, p. 1545.

ALDEHYDE. (C_2H_4O.) *Acetic Aldehyde. Acetaldehyde. Aldéhyde acétique* (*vinique*), Fr. Al-

dehyde is a generic term understood by chemists to apply to a class of bodies holding an intermediate position between the alcohols and the acids derived from them by oxidation. And, as with alcohol, when the kind is not mentioned, ethylic alcohol is always understood, so acetic aldehyde is always meant when the term aldehyde is used. The word means alcohol deprived of hydrogen (*alcohol dehydrogenatum*). (Liebig.) Aldehyde may be prepared in many ways: usually, however, by the oxidation of alcohol in some form. W. and R. Rodgers (*J. P. Chem.*, 40, 248) give the following. 1 part of alcohol sp. gr. ·842, and 1 part of potassium bichromate, are introduced in a large tubulated retort, and 1½ parts of sulphuric acid dropped in through the tubulure. Sufficient heat is evolved to start the distillation, but heat must be applied towards the end. The distillate is slightly contaminated with acetic acid. If the aldehyde be desired pure, the distillate is to be mixed with twice its volume of ether, surrounded with cold water, and dry ammoniacal gas passed in to saturation. Aldehyde-ammonia crystallizes out. This is to be decomposed in a retort by a mixture of 3 parts of sulphuric acid and 4 parts of water, and the distillate rectified and dried by contact with calcium chloride. Aldehyde is a colorless, mobile, inflammable liquid, having a decidedly pungent, ethereal, and suffocating odor. Its sp. gr. is 0·790, and boiling point 22° C. (71·6° F.). It mixes in all proportions with water, alcohol, and ether, and is rapidly converted into acetic acid on exposure to the air, through absorption of oxygen. It possesses very marked antiputrescent properties, meat being preserved for months by its 2 per cent. aqueous solution. The intoxication caused by it in animals is characterized by a very great loss of sensibility. It appears to paralyze the vagi, although its cardiac action is comparatively feeble. Upon the respiration it exerts a most powerful influence, in small doses quickening it, in large doses depressing it. The temperature is much diminished. Locally it is very irritating. (*Med. Times and Gaz.*, Sept. 1875.)

Iodaldehyde may be made by mixing iodine, iodic acid, and a solution of aldehyde together, and separating by adding water. (See paper by P. Chautard, *P. J. Tr.*, 1886, 224.)

ALETRIS. *Star Grass. Alétris farineux*, Fr. *Mehlige Aletris*, G. *Aletris farinosa. Blazing Star. Mealy Starwort. Colic Root.* (Nat. ord. Liliaceæ.) An indigenous perennial plant, the leaves of which spring immediately from the root, and spread on the ground in the form of a star. The root, which was formerly included in the U. S. secondary list, is small, crooked, branched, blackish externally, brown within, and intensely bitter. The bitterness is extracted by alcohol, and the tincture becomes turbid upon the addition of water. The decoction is moderately bitter; but much less so than the tincture. It affords no precipitate with the salts of iron. (Bigelow.) In small doses (ten grains, or 0·647 Gm.) it appears to be a simple bitter tonic. In very large doses it is said to be cathartic and emetic. It has been employed, with asserted benefit, in *colic*, *dropsy*, and *chronic rheumatism*. (See *Extractum Aletridis Fluidum.*, N. F.)

ALEURITES TRILOBA, OIL OF. The *Aleurites triloba*, Forst., is a small tree belonging to the Euphorbiaceæ. It is widely diffused through the tropics, being indigenous in the East Indies and islands of the Pacific, and naturalized in the West Indies. The fruit is a nut nearly as large as a walnut, consisting of a thick shell enclosing a kernel containing much azotized matter and rich in oil, of which it is said to yield nearly one-half its weight by expression. The nuts, strung together on the fibres of the palm-leaf, are used in the South Pacific islands as a substitute for candles. The oil has been long known in the various countries inhabited by the plant, being called in Jamaica *Spanish walnut oil*, in India *Belgaum walnut oil*, in Ceylon *kekune oil*, and in the Sandwich Islands *kukui oil*. It may be obtained by boiling with water the kernels previously beaten in a mortar, or by expression. Sixteen pints of kernels yield about three pints of oil. The yearly product of the Sandwich Islands is said to be 10,000 gallons. (M. C. Cooke, *P. J. Tr.*, Nov. 1860, 282.) The oil is very fluid, of an amber color, without smell, congealing at 32° F., insoluble in alcohol, readily saponifiable, "and very strongly drying." It is said to be a mild cathartic, acting upon the intestines in the same manner as castor oil, but causing no nausea or griping, and having the further advantages of a nutty flavor and of being more prompt in its effects. (*Journ. de Pharm.*, 3e sér., xxiv. 228.) The dose is from one-half to one ounce (14·78–29·57 C.c.), the smaller quantity generally answering. The cake left after the expression of the oil, given to a dog in the dose of about half an ounce (15·5 C.c.), produced no vomiting, but acted strongly as a purgative.

The oil of the *Tung Tree*, *Aleurites cordata* (the synonyms being *Elæococca cordata*, *Elæococca vernicia*, *Dryandra cordata*, and *Dryandra vernicia*), is enormously used in the arts in China, under the name of *wood oil*. It has a brown color and a disagreeable odor, is rather more fluid than castor oil, and on exposure dries rapidly. According to R. H. Davies, its sp. gr. at 60° F. is 0·94015; it remains liquid at —13·3° C. (8° F.). 100 Gm. of the oil require 0·39 Gm. caustic potash for neutralization, and 21·1 Gm. for complete saponification. (*P. J. Tr.*, 1885, 636.) E. M. Holmes believes that this dark-colored oil is made by boiling the kernels previous to expression, the cold-drawn oil being colorless, inodorous, and nearly tasteless. The latter, according to Cloëz (*Compt.-Rend.*, 1875, vol. lxxxi. 469), has the sp. gr. 0·9362, congeals at —18° C. to a transparent mass, solidifies rapidly when exposed to light in a closed vessel, and is the most drying oil known. It is used in *skin diseases*, and for *ulcerated wounds* and *carbuncles*, but principally for varnishing.

ALGAROBILLA, the pod of *Balsamocarpon brevifolium*, Clos., *Cæsalpinia brevifolia*, Baill. (nat. ord. Leguminosæ), a drug containing over 60 per cent. of tannin and a quantity of *ellagic acid*, is obtained from Chili. (Gehe's Report, *N. R.*, 1878, 332; *Journ. Chem. Soc.*, 1891, 918.)

ALISMA PLANTAGO-AQUATICA. L. *Water Plantain. Plantain d'Eau, Pain de Grenouilles*, Fr. *Froschlöffel, Wasserwegerich*, G. (Nat. ord. Schenchzeriaceæ.) A perennial herbaceous plant, common to Asia, Europe, and the United States, and growing in streams, pools, ditches, and other standing waters. The *root* has when fresh an odor like that of Florentine orris, but loses it when dried. Its taste is acrid and nauseous. It contains a pungent volatile oil and an acrid resin, to which all its virtues must be ascribed. The Calmucks in Russia are said to use it for food. The *leaves* are rubefacient, and will sometimes even blister. They

have been recommended in *gravel* and *complaints of the bladder* in the dose of a drachm (3·88 Gm.).

ALKANET. *Alkanna. Orcanette*, Fr. *Alkannawurzel*, G. This is the root of *Alkanna tinctoria*, Tansch. (*Anchusa tinctoria*, L.), or *dyers' alkanet*, an herbaceous perennial plant, of the nat. ord. Borraginaceæ, growing in the Grecian Archipelago and the south of Europe. It is said in some medical works to be cultivated abundantly in the south of France; but another plant is probably referred to—*Lithospermum tinctorium* of Linnæus and De Candolle, *Anchusa tinctoria* of Lamarck—which is a native of that country, and the root of which is considered as the true alkanet by the French writers. Others regard *Lawsonia inermis* as the source of true alkanet. For an account of Syrian alkanet and allied plants, see *Proc. A. P. A.*, 1896, 565. Alkanet, as found in the shops, is in pieces three or four inches long, from the thickness of a quill to that of the little finger, somewhat twisted, consisting of a dark red, easily separable bark, and an internal ligneous portion, which is reddish externally, whitish near the centre, and composed of numerous distinct, slender, cohering fibres. As it comes to us it is usually much decayed internally, very light, and of a loose, almost spongy texture. The fresh root has a faint odor, and a bitterish, astringent taste; but when dried it is nearly inodorous and insipid. Its coloring principle, which abounds mostly in the cortical part, is soluble in alcohol, ether, and the oils, to which it imparts a fine deep red; but is insoluble in water. It may be obtained by first exhausting the root with water, and then treating it with a weak solution of potassium or sodium carbonate, from which the coloring principle may be precipitated by an acid. According to Pelletier, by whom it was discovered, it possesses acid properties, forming with the alkalies and earths neutral compounds, which are of a blue color, and soluble in alcohol and ether. Its weak acid character resembles that of alizarin. Indeed, it is chemically related, as when distilled with zinc-dust it yields methyl-anthracen. It has also received the names of *anchusin* and *alkannin*. The *anchusin* has been extracted and studied by C. J. S. Thompson. (*A. J. P.*, 1886, 409.) He finds it to vary in amount between 5·25 and 6·02 per cent. It is red, resin-like, insoluble in water, soluble in oils, alcohol, chloroform, and ether, and with a rich deep blue color in alkali hydrates, the color changing again to crimson on addition of an acid. The author recommends its use in place of litmus as an indicator. The extract obtained by evaporating the tincture is dark brown. Alkanet is somewhat astringent, and was formerly used in several diseases; but it is now employed exclusively for coloring oils, ointments, and plasters, which are beautifully reddened by one-fortieth of their weight of the root. The best way to use it with this object in view is to suspend the alkanet, after tying it in a piece of flannel, in the melted fat. It is said also to be used in the preparation of spurious *port wine*.

ALLAMANDA CATHARTICA, L., is a shrub of the nat. ord. Apocynaceæ, growing in Porto Rico, the extract of whose bark is said to be an excellent hydragogue cathartic, in doses of from one to two grains (0.065–0·13 Gm.).

ALLIARIA OFFICINALIS. *Sisymbrium Alliaria*, Scop. *Erysimum Alliaria*, L. *Alliaria Alliaria* (L.), Brit. *Hedge Garlic.* A perennial European herb, a native also of Northern Asia, and naturalized from Canada to Virginia, having an alliaceous odor when rubbed, and a bitterish, somewhat acrid taste. When eaten it communicates its smell to the breath. Mr. Wertheim obtained from the root a volatile oil, apparently identical with that of mustard. (*Ann. der Chem. und Pharm.*, liii. 52.) The herb and seeds are esteemed diuretic, diaphoretic, and expectorant, and as an external application in *gangrenous affections*, and to promote *suppuration*.

ALLYL TRIBROMIDE. ($C_3H_5Br_3$.) *Tribromhydrin.* This incorrectly named substance is a colorless or faintly yellowish liquid at the ordinary temperature, but solidifying when cooled below 10° C. (50° F.) to a mass resembling a stearopten, and having a specific gravity of 2·430, which has been used with alleged good results in *hysteria* and *asthma*, given in capsules containing each five drops. (*Pharm. Post*, Dec. 1888.)

ALNUS GLUTINOSA. (L.) Medic. *Common European Alder. Black Alder. Aune noir*, Fr. *Erlenrinde, Schwarzerle Eller*, G. (Nat. ord. Betulaceæ.) A European tree twenty-five feet or more in height, growing in swamps, on the sides of streams, and in other damp places. The bark and leaves are very astringent, and somewhat bitter. The former has been used in *intermittent fever*, the latter as a topical remedy in *wounds* and *ulcers*. The bruised leaves are sometimes applied to the breast for the purpose of repelling the milk. The astringent cones are used in making gargles. All these parts of the tree are used in dyeing, and the leaves and bark in tanning. According to Eitner, the bark contains from 16 to 20 per cent. of tannic acid. (*Gerber*, 1878, 85 and 124.) The tannic acid, however, appears to differ from that of galls and oak bark, as, according to Dr. Stenhouse, it does not yield glucose when acted on by sulphuric acid. (*P. J. Tr.*, Dec. 1861.) F. Dreykorn and E. Reichardt, however, state that it is resolved by sulphuric acid into *alnine red* and sugar. (*A. J. P.*, xlii. 403.) *Alnus serrulata*, or common *American alder*, and *Alnus incana*, or *Tag alder*, appear to have analogous properties. The latter has been strongly commended as a hæmostatic. (*N. R.*, Jan. 1872.)

ALPHOL. *Salicylic Ether of Alpha-naphtol*, $C_{17}H_{12}O_3\left(C_6H_4\begin{cases}OH\\COOC_{10}H_7\end{cases}\right)$, is obtained by reaction between salicylic acid and alpha-naphtol. It is a white, crystalline powder, melting at 83° C. Soluble in alcohol, ether, and fixed oils; insoluble in water. It is used as an antiseptic and antirheumatic. Dose, from eight to fifteen grains (0·5–1 Gm.).

ALSTONIA CONSTRICTA. F. Muell. *Bitter Bark. Australian Fever Bark.* An apocynaceous tree of New South Wales and Queensland, whose yellowish-brown, thick, deeply fissured bark is said to be used by English brewers. F. V. Müller and A. Rummel obtained from it a proximate principle supposed to be an alkaloid, which they named *alstonine*. Oberlin and Schlagdenhauffen found in 1879 another alkaloid, *alstonicine*. Hesse subsequently analyzed the bark and found *alstonine*, the *chlorogenine* of a former investigation, which has the composition $C_{21}H_{20}N_2O_4$, *porphyrine*, $C_{21}H_{25}N_3O_2$, and *alstonidine*. The alkaloids and their salts in acidulated solutions show decided blue fluorescence. The bark has been successfully used in intermittent fevers. (See *Dita Bark.*)

ALUMINUM SALTS. Locally the salts of aluminum are, many of them, distinctly astringent.

For official salts of alumina, see page 144. The *aluminum acetate* as well as the *subacetate* have been employed to some extent in medicine as a substitute for the sulphate. The deliquescent acetate may be obtained by the direct combination of hydrated alumina with acetic acid, or by reaction between aluminum sulphate and lead acetate, $Al_2(SO_4)_3 + 3Pb(C_2H_3O_2)_2 = 3PbSO_4 + Al_2(C_2H_3O_2)_6$. *Alsol*, a 50 per cent. aqueous solution of *aluminum aceto-tartrate*, has been patented. It is used as a gargle. (*Pharm. Era*, 1898, 362.)

Under the names of *chloralum* and *chloralum powders* have been put upon the market as disinfectants (though in fact extremely feeble and uncertain in their action) certain mixtures containing *aluminum chloride*, which may be prepared by double decomposition between aluminum sulphate and calcium chloride in solution, the resulting calcium sulphate being separated by filtration and the chloride obtained in crystals by evaporation at a very gentle heat. Mr. Rogers Harrison claims to have obtained very good results in *gonorrhœa* from *aluminum tannate*. (*London Med. Gaz.*, xiii.; also *A. J. P.*, xxv.)

Aluminum boroformicum occurs in lustrous crystals, and may be prepared by introducing freshly precipitated alumina into a mixture of two parts of formic acid, one part of boric acid, and seven parts of water. The solution is evaporated and crystallized. (*Pharm. Rund.*, 1894, 256.)

Even the soluble salts of aluminum have very little influence upon the general organism, but Siem (*Ueber die Wirkung des Aluminiums und des Berylliums auf den thier. Organismus*, Dorpat, 1886) has shown that the *aluminum* and *sodium lactate* or *tartrate*, given in sufficient doses, will produce in frogs and also in mammals a centric general muscular relaxation, deepening into a complete loss of reflex excitability, and general paralysis. When administered in continuous doses for a series of days, these salts cause in the lower animals loss of appetite, constipation, depression, lessening of general sensibility, pronounced apathy with great weakness, ending commonly in paralysis with convulsive tremblings, fall of temperature, stupor, and death, which sometimes occurs in the midst of tetanic convulsions, more usually through an almost imperceptible diminution of the respiratory movement. These results have been confirmed by Döllken (*Archiv f. Exper. Path. u. Pharm.*, Bd. xl., 1897), who finds the symptoms to be due to an action exerted upon the nerve-centres, with demonstrable anatomical changes in the ganglionic cells.

ALUMNOL. *Aluminum Naphtol Sulphonate.* A whitish, not hygroscopic powder, easily soluble in cold water and glycerin, slightly soluble in alcohol, which has been locally used as a powerful astringent, desiccant, and antiseptic. Though it coagulates albumen, it is said to be dissolved in an excess of albumen, and, therefore, to be able to reach deep recesses of wounds. It has been strongly recommended in nasal, urethral, and other catarrhal inflammations. The strength of the solution employed varies from 1 per cent. in *gonorrhœa* to 10 per cent. in *abscesses*. (See *Berl. Klin. Wochensch.*, 1892; *Dermatologen-Congress zu Wien*, 1892; *Therap. Monatsch.*, 1892, 644.) In *laryngitis* from two to ten parts to ten parts of starch has been highly commended for use by insufflation. It is probably an *aluminum naphtol-sulphonate*.

AMANITA. Of the fungus genus Amanita, some species, such as *A. cæsarea*, are edible, whilst many others are violently poisonous. Among these may be mentioned the *A. phalloides*, or *skunk mushroom* and the *A. muscaria*, or *fly fungus*. The most characteristic symptom of poisoning by the former is the saffron color, deepening as the poisoning progresses into purple, of the urine; the symptoms otherwise resembling those caused by the more notorious *A. muscaria*, which has been employed from time immemorial by the Tartars as a means of producing intoxication. *A. pantherina*, used in Japan as a fly poison, is said to be exceedingly active. According to Dr. Inoko, it contains 1 per cent. of a mixture of alkaloids, the greater part of which is *choline* and the rest *muscarine*. It grows chiefly in woods and under trees, and is variable in color, being found scarlet, carmine, orange, greenish yellow, pale brown, and even white in hue. The pileus, which is often seven or eight inches in diameter, is covered with whitish, angular warts or spongy scales, which when moist are viscid. When growing it is convex, but becomes flat or depressed when it has attained its full size; the stem is not so solid as that of the mushroom, and is bulbous below, and covered at the base with scales. The gills are white and broad.

The active principles of probably all poisonous species of amanita are *choline* (see page 603) and *muscarine*, $C_5H_{15}NO_3$. Choline was first prepared by Strecker in 1849, from bile. It has been found by Boehm in various mushrooms, and by Brieger as one of the ptomaines of putrefying meat. Chemically it is the trimethyl-oxyethylammoniumoxyhydrate. It causes in the frog general muscular paralysis, similar to curare, due to paralysis of the motor nerve-endings. On the non-striated muscles it acts as a stimulant; it is also an excitant to the salivary, lachrymal, gastric, and probably other glands; it has no action on the biliary secretion; it stimulates slightly the vaso-motor centres, causing a rise of pressure, followed later by a fall below the normal. The primary rise of pressure is not dependent on the asphyxia which the drug causes. (Unpublished Research, Horatio C. Wood, Jr.) It will be seen from this summary of its action that choline is very similar in its pharmacology, as it is in its chemistry, to muscarine, from which it differs principally in acting less powerfully on the cardiac inhibitors, and in causing death by paralysis of the respiration. It differs apparently from its congener *neurine* principally in its action on the motor nerves.

Muscarine was first obtained by MM. Schmiedeberg and Koppe in a state of purity. (*Das Muscarin*, Leipzig, 1869.) The alkaloid may be produced artificially by gently heating choline platinochloride with strong nitric acid. Potassium chloride is used to decompose the muscarine platinochloride and produce muscarine hydrochloride; treatment with moist silver oxide yields the muscarine as a hydrate ($C_5H_{13}NO_3H_2O$). Muscarine resembles physostigmine somewhat in its physiological action, and is antagonistic to atropine, producing free salivation and weeping, vomiting, diminution of the force and frequency of the pulse, dyspnœa, great muscular weakness deepening into paralysis and finally death, usually by arrest of respiration. The pupil is intensely contracted, but dilates before death. The diastole of the heart is very much prolonged, and after very large doses diastolic arrest occurs. This

is due to an action upon the inhibitory nerves, and if atropine be given so as to paralyze them the cardiac movements reoccur. The vaso-motor nerves are said to be paralyzed. The action on the abdominal viscera is very marked. The muscles of the intestines, bladder, and spleen are tetanically contracted. Thus the intestines are transformed into hard white cords, or afterwards, becoming somewhat relaxed, exhibit a tumultuous peristalsis. The abdominal secretions are greatly increased. Most of the physiological results obtained by Schmiedeberg and Koppe have been confirmed by M. J. L. Prevost. (*Journ. de Pharm.*, 4e sér., xx. 385; *Congrès Méd. Internat.*, *Comptes-Rendus*, Geneva, 1878. See also *Arch. f. Exper. Pathol. u. Pharm.*, xxxi.)

AMARANTHUS HYPOCHONDRIACUS. L. *Prince's Feather.* (Nat. ord. Amarantaceæ.) This annual, growing sparingly in the Middle United States, is said to be an astringent.

AMBERGRIS. *Ambra Grisea (cinerea)*. *Ambre*, *Ambregris*, Fr. *Amber*, *Graue Ambra*, G. This substance, which is found floating on the sea, or thrown by the waves upon the shores of various countries, particularly in the southern hemisphere, is now generally believed to be produced in the intestines of the *Physeter macrocephalus*, or spermaceti whale, and perhaps in those of some other fish. It is in roundish or amorphous pieces, usually small, but sometimes weighing as much as 50, 100, or even 200 pounds. These pieces are often composed of concentric layers. They are of various colors, usually gray, with brownish, yellow, and white streaks, often dark brown or blackish on the external surface. They are opaque, lighter than water, and of a consistence like that of wax. Ambergris has a peculiar aromatic agreeable odor, is almost tasteless, softens with the warmth of the hand, melts under 100° C. (212° F.), is almost completely volatilizable by heat, and is inflammable. It is insoluble in water, but is readily dissolved, with the aid of heat, by alcohol, ether, and the volatile and fixed oils. It consists chiefly of a peculiar fatty matter analogous to cholesterin, and denominated by Pelletier and Caventou *ambrein*. This may be obtained by treating ambergris with heated alcohol, filtering the solution, and allowing it to stand. Crystals of ambrein are deposited. It is incapable of forming soaps with the alkalies. When pure it has little or no odor. Ambergris is often adulterated, but does not then exhibit its ordinary fusibility and volatility. It was long regarded as a cordial and antispasmodic, somewhat analogous to musk; useful in *typhoid fevers*, and various nervous diseases. It formerly entered into many official preparations, and is still retained in some European Pharmacopœias. The French Codex directs a tincture to be prepared by macerating, for ten days, 100 parts of powdered ambergris with 1000 parts of alcohol at sp. gr. 0·864, expressing and filtering. M. Stan. Martin assures us that the tincture will keep better, deposit nothing, and have a more agreeable odor, if the ambergris, instead of being merely powdered in a mortar, be subjected to porphyrization, especially with the addition of washed sand. Heat, he says, should never be used in its preparation. (*Journ. de Pharm.*, 4e sér., i. 448.) It is, however, feeble as a remedy, and is chiefly used in perfumery. The dose is from five grains to a drachm (0·324–3·88 Gm.).

AMBROSIA TRIFIDA. L. *Ragweed. Ambrosie*, Fr. *Traubenkraut*, G. (*Gray's Manual*, 212.) (Nat. ord. Compositæ.) This and another indigenous annual, *A. artemisiæfolia*, L., have found a place in the Materia Medica of the eclectics, by whom they are deemed astringent and somewhat stimulant, and are given in low forms of fever. Dr. J. Hill (*N. Carolina Med. Journ.*, 1885, 16) affirms that the decoction is a powerful hæmostatic in *epistaxis* and *internal hemorrhages*. L. W. Schwab has found in *A. artemisiæfolia* a bitter glucoside. (*A. J. P.*, 1890.)

AMIDOACETAL. $H_2N.CH_2CH(O.C_2H_5)_2$. According to the experiments of A. Mallèvre (*Arch. f. Physiol.*, xlix.), this substance is an active poison, causing death in mammals by paralysis of the respiratory centre.

AMIDOPHENOLS. (Derivatives of *p-amidophenol*, $C_6H_4(OH)NH_2$.) In an elaborate series of experiments (*Centralb. f. Innere Medicin*, 1897) Treupel and Hinsberg find that derivatives from amidophenol are active as antipyretics in proportion as they are decomposed in the system, and that the decomposition is to be measured by the amount of indophenol in the urine. The most important of these substances is *Dulcin*, called also *Para-phenetolcarbamide*, *Valzin*, and *Sucrol*, $CO\begin{cases} NH.C_6H_4.OC_2H_5 \\ NH_2 \end{cases}$, which occurs in colorless crystals, melting at from 173°–174° C., soluble in 800 parts of cold and 55 of boiling water, and 25 of alcohol, having a taste which is said to be two hundred times sweeter than sugar. It has been recommended as a substitute for sugar in *diabetes*, and, on account of its slight solubility, to improve the flavor of castor, cod-liver, or other oils. According to Treupel and Hinsberg, fifteen grains of it will reduce the temperature in fever about one degree centigrade in the course of about three hours, and no unaltered dulcin is to be found in the urine, but indophenol.

Besides dulcin, Treupel and Hinsberg examined physiologically the following amidophenol derivatives: *Lactylamidophenolethylcarbonate*, *Benzoylacetamidophenol*, *Ethyldiacctamidophenol*, *Oxyphenacetinsalicylate*.

AMINOL. This is an antiseptic liquid, colorless, slightly turbid, and having the odor of trimethylamine. It is alkaline in reaction. Sp. gr. 1·01. It is obtained commercially from herring pickle. A tablespoonful diluted with two tablespoonfuls of water may be used for a lotion, gargle, or spray.

AMMI VISNAGA. Lam. The fruit of this umbelliferous plant, indigenous in the countries around the Mediterranean, contains a crystalline principle, *kellin* (*Compt.-Rend.*, Aug. 25, 1879), which is asserted in *Union Méd.*, April, 1886, to act upon the heart and spinal cord. Mild antipyretic and antilithic properties have been attributed to the fruit.

AMMONIATED IRON. *Ferrum Ammoniatum. Ammoniated Iron. Ammonio-chloride of Iron. Ammonii et Ferri Chloridum. Ammonium Chloratum Ferratum. Sel Ammoniac Martial*, Fr. *Eisensalmiak*, G. This drug was formerly recognized both by the U. S. and London Pharmacopœias, which contained formulas for its preparation. (See *U. S. Dispensatory*, 15th edition, 1568.) There is no reason to believe that the ferric chloride and ammonium chloride are chemically combined in the preparation. According to Mr. Phillips, they are in the proportion of 15 parts of the iron to 85 of the ammonium salt.

Ammoniated iron is in crystalline grains, of a fine reddish-orange color, and a sharp, styptic, saline taste. It is entirely soluble in water and diluted alcohol, is deliquescent, and should be kept in well-stoppered bottles. As procured by sublimation (*Flores martiales*, *Ens martis*), it is of a yellow color and feeble odor. It unites aperient with chalybeate properties, and is said to have been used with advantage in *amenorrhœa*, *epilepsy*, *scrofula*, *rickets*, etc.; but it is at best uncertain, and is now very seldom prescribed. The dose is from four to twelve grains (0·259–0·775 Gm.).

AMMONII SULPHAS. *U. S.* 1880. *Sulphate of Ammonium.* $(NH_4)_2SO_4$; 132. *Ammonium Sulphuricum. Sal Ammonium Secretum Glauberi. Sulfate d'Ammoniaque*, *Sel secret de Glauber*, Fr. *Schwefelsaures Ammon*, *Ammonium*, *Ammoniak*, G. Gas liquor is distilled with lime and the gas received in sulphuric acid, which yields a purer product. Most of the ammoniacal liquor is worked up into the ammonium sulphate at present. The English production from gas-works, shale distilling, and coke ovens now amounts to about 200,000 tons annually, that of Germany to 100,000, and France 35,000 tons. In the United States the production from gas-works amounted ten years ago to 11,000 tons, and has probably not increased because of the general introduction of water-gas processes, in which no ammoniacal liquor is formed; on the other hand, the production in connection with the coking of coal has increased very rapidly since 1897; at that time it was over 3000 tons, and is now probably 20,000 tons. "Colorless, transparent, rhombic prisms, permanent in the air, odorless, having a sharp, saline taste and a neutral reaction. Soluble in 1·3 parts of water at 15° C. (59° F.) and in 1 part of boiling water; insoluble in absolute alcohol, but slightly soluble in alcohol of sp. gr. 0·817; when heated to about 140° C. (284° F.), the salt fuses, is gradually decomposed, and on ignition is wholly dissipated. The aqueous solution of the salt, when heated with potassa, evolves vapor of ammonia. With test-solution of chloride of barium it yields a white precipitate insoluble in hydrochloric acid. A 1 per cent. solution of the salt should not be blackened by test-solution of sulphide of ammonium (lead and iron), nor, when acidulated with nitric acid, should it be rendered more than opalescent by test-solution of nitrate of silver (limit of chloride)." *U. S.* 1880. It is not used as a medicine, but enters into the composition of ammonia-alum and the iron and ammonium sulphate.

AMMONII URAS. *Ammonium Urate.* $C_5H_3(NH_4)N_4O_3$. This is an acid salt, and may be formed by digesting uric acid in solution of ammonia, or by adding sal ammoniac to the solution of other urates. Uric acid is generally obtained from the dried and powdered excrement of the boa serpent, and of other large snakes, by dissolving it in a weak solution of potassa with the aid of heat, and precipitating the uric acid from the filtered solution by hydrochloric acid, added in excess. Ammonium urate is a white, amorphous, very sparingly soluble salt. It is a constituent of some varieties of guano. It has been used with asserted good effects externally in chronic *eczema*, in the form of an ointment (twenty grains to the ounce). (See 16th edition *U. S. D.*) Dr. Neubauer found that when given internally to rabbits it causes increase in the urea, uric acid, and oxalates of the urine. (*Ranking's Abstract*, 1857.)

AMMONIUM ARSENATE. *Ammonii Arsenas.* $(NH_4)_2HAsO_4$. This salt is obtained in crystals by saturating a concentrated solution of arsenic acid with ammonia or ammonium carbonate, and allowing it to evaporate spontaneously. The crystals, which belong to the trimetric system, effloresce on exposure to the air, and lose half their ammonia. Its solution is alkaline. It has been used with advantage by Biett in several inveterate *diseases of the skin*. It is administered in solution, one grain of the salt in a fluidounce of distilled water. Of this the dose is from twenty to twenty-five drops, given in divided portions in the course of the day, and gradually increased.

AMMONIUM BICARBONATE. *Acid Carbonate of Ammonium.* $H(NH_4)CO_3$. This salt was brought into notice by Prof. Wm. Procter, in reference to its antacid properties. It is formed by exposure of the ordinary carbonate to the air, and is found in considerable quantities on the sides of casks in which that salt is imported, and less largely even in the bottles in which it is kept in the shops. Crystals of this salt are sometimes found in Patagonian guano and in the purifiers of gas-works. When pure, the ammonium bicarbonate is white, having the same crystalline form as potassium bicarbonate, of a saline slightly ammoniacal taste, and a feeble odor of ammonia, ascribable to a very slow volatilization. On exposure to heat, it gives off carbonic acid. It is soluble in eight parts of water at 15·6° C. (60° F.), is nearly insoluble in official alcohol, but soluble in diluted alcohol; and its solution has an alkaline reaction with syrup of violets. It may be prepared by treating commercial ammonium carbonate (ammonium sesquicarbonate) with official alcohol, whereby the neutral carbonate is dissolved and the bicarbonate left. To render this still purer it should be washed with alcohol and dried. It is obtained as a crystalline precipitate by adding alcohol to a saturated solution of the ordinary carbonate, or by passing carbonic acid through the same solution. It may be used as an antacid in the same manner and the same doses as sodium bicarbonate, being preferable to that salt when a stimulant impression on the stomach is desired. (*A. J. P.*, July, 1869, 294.)

AMMONIUM BORATE. *Ammonium Biborate.* $2(NH_4HB_2O_4)3H_2O$. Only acid salts are known. The salt usually formed by dissolving boric acid in ammonia solution and heating until the excess of ammonia is driven off is, according to Gmelin, confirmed by Rammelsberg, $BO_2NH_4 + 3HBO_2 + 1\frac{1}{2}H_2O$. By dissolving one part of boric acid in excess, in three parts heated water of ammonia, sp. gr. 960, and allowing the solution to cool slowly, this salt is obtained in crystals. These are rhombic octahedrons, with truncated summits, and often truncated edges, and are semi-transparent. The taste of the salt is alkaline, and it has an alkaline reaction. On exposure, it effloresces, losing ammonia, and becoming in time the quadriborate. It is soluble in about twelve parts of water. (*Gmelin*, ii. 435.) M. Beeker has used it with asserted great advantage in *stone in the bladder* and *renal colic*. Under its influence the urine becomes loaded with uric acid and the earthy phosphates. It is said also to be an excellent remedy in *chronic catarrh of the bladder*. It is believed by M. Beeker to be the *ludus* of Paracelsus, which had a great reputation in the treatment of urinary calculi. It may be given in the dose of from ten to twenty grains

(0·648–1·29 Gm.) every hour, in water sweetened with liquorice. (*Journ. de Thérap. Méd.-Chir.*, Sept. 1, 1866.)

AMMONIUM EMBELICUM. According to the experiments of G. Coronedi (*Sperimentale*, 1892, fasc. 2), this substance is a practical anthelmintic in *tapeworm*. Dose, one-fifteenth of a grain (0·005 Gm.), in pill, three times a day for a child, seven times a day for an adult.

AMMONIUM PERSULPHATE, $(NH_4)_2S_2O_8$, is prepared by electrolyzing an acid solution of ammonium sulphate, and is a most efficient oxidizing agent in acid, neutral, or alkaline solutions. It occurs in small colorless crystals, soluble in water. Its solution evolves oxygen when heated, and is used as an antiseptic for preserving meat and other food, and as a cheap and effective mouth-wash.

AMMONOL. This proprietary remedy is stated by its manufacturers to be *Ammoniated-Phenylacetamide*. It has been used internally as an analgesic in doses of from five to ten grains. According to the analysis of Mr. George M. Beringer (*A. J. P.*, lxix.), it is composed of acetanilid, 10 grammes; sodium bicarbonate, 5 grammes; ammonium bicarbonate, 5 grammes; metanil-yellow, 0.005 gramme.

AMYGDOPHENIN. *Ethyl Amygdophenin.* This is a derivative of *p-amidophenol*, analogous to phenacetin. In constitution it is a light crystalline greenish-white powder, soluble with difficulty in water. It is obtained by the action of mandelic acid upon *p-phenetidin* in the presence of dehydrating agents. R. Stüve asserts that it is practically free from antipyretic properties; that it is an analgesic which is often useful in *neuralgias* and the pains of *spinal scleroses;* and that it is very useful in *rheumatism*, it having had more effect in some comparative trials than the salicylates. It is best administered in capsules, one gramme from three to six times a day.

AMYL VALERIANATE. The *valerianate of amyl* is said by Dr. W. F. Wade, of Birmingham, to act similarly to valerian, and to afford a most elegant remedy. He dissolves one part of it in nineteen parts of alcohol and 2 per cent. of a spirit of amyl acetate (one part to twenty). The dose of this mixture is from six to eight drops.

AMYLAMINE HYDROCHLORATE, *Amylamine Chloride*, $C_5H_{13}N,HCl$, crystallizes either in efflorescent scales or in quadratic octahedrons. According to M. Dujardin-Beaumetz (*Comptes-Rendus*, lxxvii. 1247), in small doses (from one to five centigrammes to a rabbit) this salt lowers the temperature and also the force and frequency of the pulse. In larger amounts it produces profound nervous disturbance, with tonic and clonic convulsions, ending often in death. In man, doses of from seven to fifteen grains (0·460–0·972 Gm.) diminish the pulse and temperature.

From amylamine hydrochlorate by boiling with an excess of calcium chloride is formed *amyldichloramine*, a yellowish-green oily liquid, the smelling of which produces violent irritation of the nose, followed by severe headache and vertigo. According to the researches of Boinet (*Congrès Français de Méd.*, 1, 1894), it is not only a violent local irritant, but also a powerful centric poison, producing death by asphyxia. Boinet has also examined physiologically *propyldichloramine* and *isobutyldichloramine*, finding that they are similar in their toxic influence to amyldichloramine.

AMYLENE. *Valerene. Pentene.* C_5H_{10}. This compound was alluded to under amylic alcohol. The name is given to the isomeric hydrocarbons of the *olefin* series, having the formula C_5H_{10}, of which five are possible. Amylene is prepared by distilling amylic alcohol with a concentrated solution of zinc chloride, which acts by dehydrating and withdrawing a molecule of water. The product is redistilled, and that which comes over first, constituting the more volatile part, is separately collected, and agitated with concentrated sulphuric acid, when the amylene, freed from water, will rise to the surface. Amylene is a colorless, very mobile liquid, having the density 0·655 at 10° C. (50° F.). Its boiling point is 34° C. (93·2° F.). Its smell is peculiar and disagreeable. It is soluble in alcohol and ether in all proportions, but very sparingly so in water. When pure it does not act on potassium, and is not colored by a prolonged contact with caustic potassa.

In 1857, Dr. Snow, of London, proposed amylene as a new anæsthetic, claiming for it certain advantages over the older remedies. It was soon shown, however, to be too dangerous for use. Two deaths resulted from it, and the French Academy of Medicine formally condemned it.

Amylene Hydrate. *Tertiary Amyl Alcohol. Dimethylethylcarbinol* ($C_5H_{12}O$ or $(CH_3)_2C_2H_5COH$) is a clear, colorless liquid, of a strong, penetrating odor, soluble in eight parts of water, and miscible with alcohol, ether, chloroform, benzin, glycerin, and fixed oils in almost all proportions; sp. gr. 0·812 at 53·6° F. It is made by shaking together at 0° C., or under, 300 C.c. of amylene (C_5H_{10}) and 600 C.c. of sulphuric acid (equal volumes of H_2SO_4 and H_2O). The *amylensulphuric acid* is separated, diluted with iced water, filtered, neutralized with calcium carbonate, and distilled; the product is redistilled fractionally, the portion passing over between 100° and 102·5° C. (212° and 216·5° F.) being retained.

In 1887, Von Mering proposed the use of amylene hydrate as a soporific, stating that it stood midway between chloral and paraldehyde, one drachm of chloral, two drachms of amylene hydrate, and three drachms of paraldehyde being about equivalent in power. In cases of poisoning, as reported by C. Dietz, by the amylene hydrate, the symptoms were deep narcosis, dilated pupils, loss of corneal reflexes, slow, deep, irregular breathing, small, slow pulse, and fall of temperature. The general clinical reports show that amylene hydrate is a safe, rapidly acting, and occasionally useful but not analgesic hypnotic, in doses of from thirty to forty minims (1·84–2·46 C.c.).

Pental. Trimethylethylene. β-isoamylene, $(CH_3)_2C{=}CH.CH_3$, or C_5H_{10}, is obtained from crude amylene, which consists of pentane (C_5H_{12}), pental (C_5H_{10}), and *α*- and *γ*-amylene. If the mixture be shaken with diluted sulphuric acid at a low temperature, —20° C. (—4° F.), the trimethylethylene and *γ*-amylene will be decomposed and amylsulphuric acid produced, which after dilution with water yields tertiary amyl alcohol and pure trimethylethylene; by fractional distillation the pental is obtained in a pure state.

Pental is a colorless, highly inflammable liquid; sp. gr. 0·678; boiling point 100·4° F. (38° C.). It was highly commended by Dr. W. Lombardino as an anæsthetic of great practical value. H. C. Wood and David Cerna have, however, shown that pental acts upon the lower animals as a powerful cardiac

depressant, and is probably a dangerous anæsthetic. The more recent clinical trials of the drug have proved that this danger is real, there having been, according to the statistics of Gurlt, in six hundred pental narcoses, six deaths. Moreover, N. Kleindienst found that very frequently in man severe albuminuria, and not infrequently hæmaturia and hæmoglobinuria, occurred three or four days after pental narcosis.

Pentane. Amyl hydride, $CH_3.CH_2.CH_2.CH_2.CH_3$, was discovered by Dr. E. Frankland, of Manchester. It is a saturated hydrocarbon, and has been proved to be one of the light products in American petroleum, being the portion boiling at from 37°–39° C. (98·6°–102° F.) (Schorlemmer). Amyl hydride is a colorless, volatile, mobile liquid, possessing a grateful fruity odor, having no taste. It is one of the lightest liquids known, having the sp. gr. 0·626 at 17° C. (62·6° F.). It boils at 37·7° C. (100° F.), and the sp. gr. of its vapor is 2·5. It is very inflammable, and burns with a brilliant white flame. It is readily soluble in alcohol and ether, but insoluble in water. Belonging to the paraffin or saturated series of hydrocarbons, it is a very stable compound, resisting the action of fuming sulphuric acid and the most powerful oxidizing agents. This substance was proposed by Prof. Simpson as an anæsthetic, but has not sustained the claims made for it.

AMYLOFORM is a patented chemical compound of formaldehyde and starch, introduced by Classen as a substitute for iodoform. It is stated to be odorless, innocuous, and non-irritant. *Dextroform* is a similar compound, in which dextrin is used in place of starch. Dextroform is soluble in water and glycerin.

AMYTIN. Under the name of amytin, Unna has introduced into medicine a 33 per cent. aqueous solution of ichthyol-sulphonic acid, which has the property of dissolving ichthyol, various ethereal oils, phenol, and camphor, forming solutions which are known by Unna as *Amytoles*. Many of these amytoles, especially those made with a phenol, are powerfully antiseptic. The 10 per cent. cresol solution is said to entirely disinfect catgut ligatures in from thirty-six to forty-eight hours, after which time the ligatures must be removed and preserved in alcohol. Amytin is more or less irritant to the skin, and is affirmed to be useful in those skin diseases which need stimulation. It is stated that a 3 per cent. solution of the cresol amytole affords an excellent means of disinfecting the hands, and is very actively poisonous against the diphtheritic bacillus.

ANACAHUITE WOOD. In the year 1860 considerable quantities of this wood were imported from Mexico, into Germany, as a supposed remedy in *phthisis*, but it failed to sustain its first reputation. It is the product of *Cordia Boissieri*, De Cand. (See *P. J. Tr.*, Dec. 1862, 272, with figure.)

ANACARDIUM OCCIDENTALE. Linn. *Cassuvium pomiferum.* Lam. *Acajou à Pommes*, Fr. *Caschunuss*, G. *Cashew-nut.* A small and elegant tree of the nat. ord. Anacardiaceæ, growing in the West Indies and other parts of tropical America. A gum exudes from the bark, which bears some resemblance to gum arabic, but is only in part soluble in water, and consists of true gum and bassorin. It is the *gomme d'acajou* of the French writers. The fruit is a fleshy, pear-shaped receptacle, supporting at its summit a hard, shining, ash-colored, kidney-shaped nut, an inch or more in length and three-quarters of an inch broad, consisting of two shells, with a black juice between them, and of a sweet oily kernel. The receptacle is red or yellow, and of an agreeable subacid flavor with some astringency. It is edible, and affords a juice which has been recommended in *uterine complaints* and *dropsy*. This juice is converted by fermentation into a vinous liquor, which yields a spirit by distillation, used in making punch, and said to be powerfully diuretic. The nuts are well known under the name of *cashew-nuts*. The black juice contained between their outer and inner shell is extremely acrid and corrosive, producing, when applied to the skin, severe inflammation, followed by blisters or desquamation. Staedeler found in it two peculiar principles,—*anacardic acid* and a yellow, oleaginous liquid, *cardol*. (See *Journ de Pharm.*, 3e sér., xiii. 459.) The juice is used in the West Indies for the cure of *corns*, *warts*, *ringworms*, and obstinate *ulcers*, and even of *elephantiasis*. It is said to be sometimes applied to the face by females, in order to remove the cuticle, and produce a fresher and more youthful aspect. In a case of external poisoning which came under our notice, in a lady who was exposed to the fumes of the roasting nuts, the face was so much swollen that for some time not a feature was discernible. A similar case, occurring in a boy who had cut open one of the nuts, eaten a small portion raw, and by handling it had spread the juice over different parts of the body, is recorded by Dr. Monkur in the *N. J. Med. Reporter* (April, 1855, 187). The tongue, face, neck, hands, forearms, scrotum, etc., were red and enormously swollen, and very painful. The tincture of iodine was found useful as a local application. The kernel has a sweet, agreeable taste, and is eaten like chestnuts, either raw or roasted, in puddings, and as a chocolate when ground with cocoa. By age it becomes rancid. The black juice of the nut and a milky juice which flows from the tree after incision are used for, almost indelibly, marking linen.

ANAGALLIS ARVENSIS. L. *Scarlet Pimpernel. Red Chickenweed. Weather-glass. Mouron rouge*, Fr. *Gauchheil*, *Rothemiere*, G. (Nat. ord. Primulaceæ.) An annual plant, growing in Europe and this country, with small, delicate, procumbent stems, furnished with opposite branches, opposite ovate leaves, and small scarlet flowers, which are supported upon axillary, solitary peduncles, and appear in June and July. It has little smell, but a bitterish, somewhat acrid taste. The ancients esteemed it a counter-poison, and Orfila found three drachms of its extract to cause fatal gastro-enteritis in a dog. It has been recommended as a local application to old and ill-conditioned *ulcers*, and has been given internally in *visceral obstructions*, *consumption*, *dropsy*, etc. J. A. Heintzelman obtained from it a volatile oil of a strong peculiar odor, a pungent and somewhat acrid taste, and the sp. gr. 0·987. Four drops of it produced intense headache and nausea, lasting for twenty-four hours, with pains throughout the body. According to Daccomo and Tommasoli, it contains an active ferment, which rapidly digests raw meat. (*Rassegna di Sci. Med.*, 1892, No 4.) *A. cærulea* is probably a variety of *A. arvensis*, and shares its medical properties.

ANAGYRIS FŒTIDA. (Nat. ord. Leguminosæ.) Messrs. Hardy and Gallois have separated from the *Anagyris fœtida* an alkaloid, *anagyrine*, which is a respiratory poison.

ANALGEN. *Ortho-ethoxy-anamonobenzoylamido-quinoline. Benzanalgene. Quinalgene. Labordin.* $C_{18}H_{16}N_2O_2$. The name analgen was first given to the acetyl derivative, but it was found that the benzoyl radical gave a more desirable product, and this is now made exclusively and the name analgen applied to it. It is in colorless crystals, insoluble in water, soluble in hot alcohol, melting point 208° C. (406·4° F.)

First produced and brought forward by Vis as an antipyretic, analgesic, and antirheumatic remedy, it was subsequently investigated by Maass (*Zeitsch. für Klin. Med.*, xxviii., 1895), who found that in sufficient dose it depresses the heart and the reflexes, finally causing convulsions with loss of power, and death by centric paralysis of respiration. Both it and its derivative, *oxyethylamidoquinoline*, act upon the peripheral nerves as local anæsthetics. The fatal dose for the lower animals was found by Maass to be three grammes per kilo. The continuous use of small doses produces emaciation, feebleness, and lessening of the reflexes. In cases of fever it causes active depression of temperature, often with free sweating, and usually decrease in the urinary secretion, and especially of the nitrogenous elimination. After chronic poisoning in the lower animals fatal degeneration was found in the liver and kidneys. The urine of patients taking it is said to become red, owing to the presence of *oxyethylamidoquinoline urate.* In *headaches* and the other nervous disturbances of *chlorotic neurasthenic* individuals it is said to act well without affecting digestion. It is said also to relieve the pain of organic diseases, and to be distinctly anti-malarial. (See *Bull. Acad. Med.*, xxxvi.) The dose is from seven and a half to fifteen grains (0·5–0·97 Gm.), increased to seventy-five grains (4·86 Gm.) a day if required; best administered in capsule or in acidulated water.

ANCHIETEA SALUTARIS. *Cipo Suma. Cipo Carneiro. Pirageia.* The bark of the root of this Brazilian plant contains *anchietine*, an alkaloid isolated by Peckoldt. It is used in Brazil in treating *scrofula*, *erysipelas*, and *eczema.* Given in doses of two drachms it acts as an aperient, while three-drachm doses produce vomiting.

ANCHUSA OFFICINALIS. L. *Bugloss. Oxtongue.* (Nat. ord. Boraginaceæ.) This is a European biennial plant, from one to three feet high, whose root, leaves, and flowers were official. These are inodorous and nearly tasteless. The root is mucilaginous and slightly sweetish, and the flowers very feebly bitter. The plant has no claim whatever to the credit, formerly attached to it, of possessing cordial and exhilarating properties. In France, the *Anchusa Italica*, which is there known as *buglosse*, is substituted for *A. officinalis.*

ANDROGRAPHIS PANICULATA. Nees. (Nat. ord. Acanthaceæ.) This plant, which is a native of India, Ceylon, and Java, is said to have been introduced into the West Indies and Mauritius and is being marketed. It is an active bitter tonic. (*Pharm. Rev.*, 1896.)

ANDROMEDA. The *Oxydendrum arboreum*, (L.) D. C. (*Andromeda arborea*, L.), *Sour Wood*, or *Sorrel-tree*, grows in the valleys of the Alleghanies, from Pennsylvania to Florida. The leaves have a pleasant acid taste, and are used by hunters to allay thirst, and form in decoction a grateful refrigerant drink in fevers. Dr. Barton, in his *Collections* states that a decoction of *Pieris Mariana*, (L.) B. and H. (*Andromeda Mariana*, L.), is employed in the Southern States as a wash in ulcerations of the feet. The powder of the leaves and buds of *Leucothöe racemosa*, L. (A. Gray), is said to be a powerful errhine. Prof. J. F. Eykman, of Japan, found a poisonous glucoside, *asebotoxin*, in *Andromeda* (*Pieris*) *japonica.* (*N. R.*, 1882, 290.) In 1883, Prof. Plügge separated from *Andromeda japonica* a colorless crystallizable poisonous principle, *andrometoxin.* Subsequently he found that various ericaceous plants contain it. (*Arch. d. Pharm.*, xxvi.; also *A. J. P.*, 1889.) It exists in the *Azalea Indica* and *Rhododendron maximum*, and has been found by De Zaayer (*Chem. Zeit.*, July, 1887) in the *Rhododendron ponticum*, and in *Kalmia angustifolia* and *latifolia*, also in *Monotropa uniflora* by A. J. M. Lasché (*Pharm. Rundschau*, Sept. 1889). It occurs in acicular crystals, melting at from 228° to 229° C., soluble in alcohol, amylic alcohol, chloroform, ether, benzol, much more soluble in cold than in boiling water, yielding solutions of an alkaline reaction, but not precipitated by ordinary alkaloidal reagents nor by solutions of metallic salts. For further tests, see reference; also *P. J. Tr.*, vol. xviii. 171. The *poisonous honey* of Xenophon, derived from the flowers of *R. ponticum*, probably owed its toxic properties to andrometoxin. (See also *Pharm. Zeits. f. Russland*, 1883, xxii.) The oil of *A. Leschenaultii*, of India, was found by Mr. J. Broughton to be methyl salicylate. (*P. J. Tr.*, Oct. 1871.)

ANESIN. *Aneson. Anäsin.* This is a patented 1 per cent. aqueous solution of *Tri-chlor-pseudo-butyl-alcohol* or *Aceto-chloroform.* $HO.C(CH_3)_2CCl_3+1\frac{1}{2}H_2O$. This compound is obtained when acetone combines with chloroform in the presence of caustic alkalies.

It was first studied pharmacologically by J. Kossa, and subsequently by Zoltán von Vámossy. (*Deutsch. Med. Wochen.*, xxiii.) It is alleged that it is a powerful local anæsthetic, equivalent to a 2½ per cent. solution of cocaine, and having the advantage of being non-irritant and non-toxic, and of not being mydriatic. Its anæsthetic effects are said to be of slow development, as it seemingly does not pass rapidly through the mucous membrane. Internally aceto-chloroform is affirmed to resemble chloral hydrate in its hypnotic action in doses of from seven and a half to fifteen grains (0·5–0·97 Gm.).

ANGELICA. *Racine d'Angélique*, Fr. *Engelwurzel*, G. *Angelica atropurpurea*, L. (nat. ord. Umbelliferæ), sometimes called *masterwort*, has a perennial purplish root, and a smooth, dark-colored herbaceous stem. The ternate leaves are supported by very large inflated petioles. The partitions of the leaf are nearly quinate, with ovate, acute, deeply serrate, somewhat lobed leaflets, of which the three terminal are confluent. The flowers are greenish white. The purple angelica extends throughout the United States from Canada to Carolina, growing in meadows and marshy woods, and flowering in June and July. The whole plant was formerly official. It has a strong odor and a warm aromatic taste. The juice of the recent root is acrid, and is said to be poisonous; but the acrimony is dissipated by drying. The medical virtues of the plant are similar to those of the garden angelica of Europe, for which it has been proposed as a substitute. It is, however, little employed. An infusion is occasionally used in flatulent *colic*, and we are told that the stems are sometimes candied by the country people.

Angelica Archangelica, L. (*Archangelica officinalis*, Hoffm.) *Garden angelica* has a long, thick, fleshy, biennial root, furnished with many fibres, and sending up annually a hollow, jointed, round, channelled, smooth, purplish stem, which rises five feet or more in height, and divides into numerous branches. The leaves, which stand upon round fistulous footstalks, are very large, doubly pinnate, with ovate-lanceolate, pointed, acutely serrate leaflets, the terminal being three-lobed. The flowers are small, greenish white, and disposed in very large, many rayed terminal umbels, composed of numerous dense, hemispherical umbellets. This plant is a native of the north of Europe, and is found in the high mountainous regions in the southern section of that continent, as in Switzerland and among the Pyrenees. It is often cultivated. The whole plant is aromatic, but the root and the fruit only were official. The *root* should be dug up in the autumn of the first year, as it is then least liable to become mouldy and worm-eaten. It is spindle-shaped, an inch or more thick at top, and beset with long descending radicles. The fresh root has a yellowish-gray epidermis, a fleshy yellow parenchyma, and when wounded yields a honey-colored juice, having all the aromatic properties of the plant. The dried root is grayish brown and much wrinkled externally, whitish and spongy within, and breaks with a starchy fracture, exhibiting shining resinous points. It is very apt to be attacked by worms, and is said to keep best, in the state of powder, in full and well-closed vessels. The smell is strong and fragrant, and the taste at first sweetish, afterwards warm, aromatic, bitterish, and somewhat musky. These properties are extracted by alcohol, and less perfectly by water. The constituents of the root, according to the younger Buchner, are volatile oil, a volatile acid which he calls *angelicic acid*, a wax-like substance, a crystallizable sub-resin, a brittle amorphous resin, a bitter principle, tannic acid, malic acid, sugar, starch, albumen, pectic acid, fibrin, and various salts. Five hundred parts yield nearly four parts of the volatile oil. Schimmel & Co. (*Berichte*, April, 1889) report the results of an examination of *Japanese angelica*, believed to be roots of *A refracta* or *A. anomala*. It contained a small quantity of volatile oil, which had an extremely persistent odor. The *angelicic acid* of Buchner is now known as *angelic acid*, $C_5H_8O_2$, a monatomic acid of the acrylic acid series. Valerianic acid, $C_5H_{10}O_2$, has also been recognized as occurring in the root. The volatile oil has been examined by Beilstein and Wiegand, who found three terpenes: one boiling at 158° C., forming no crystallizable hydrochloride; the second boiling at 175° C. and forming a crystalline hydrochloride having the properties of artificial camphor; this second terpene forming the main body of the oil; and a third, boiling at 250° C. (*Ber. der Chem. Ges.*, 1882, 1741.) The main terpene product is now recognized as *phellandrene*. Besides valerianic (methyl-ethylacetic) acid, *oxymyristic*, $C_{14}H_{28}O_3$, and *oxypentadecylic acids*, ($C_{15}H_{30}O_3$), have been identified. (*Schimmel & Co.'s Report*, April, 1897.) The *seeds*, as the fruit is commonly called, are two or three lines long, oval, obtuse or somewhat notched at the ends, flat, with a longitudinal furrow on one side, convex with three angular ridges on the other. They are ash-colored, and have the smell and taste of the root. They are said to keep well.

Garden angelica is an elegant aromatic tonic. The Laplanders, in whose country it flourishes, esteem it highly as a condiment and medicine. In Europe the stems are frequently made into a preserve and used in desserts in order to excite the stomach. The dose of the root or seeds is from thirty grains to a drachm (1·94–3·88 Gm.).

ANGRÆCUM FRAGRANS. This is an orchidaceous plant, indigenous in the Isle of Réunion and Mauritius, where the leaves have been long used, under the name of *faham*, for the same purposes as Chinese tea. For description, see *P. J. Tr.*, 1881, 913 They have a somewhat pungent aromatic taste, and a strong and highly agreeable odor, scenting the whole apartment with a delicious perfume. Given in infusion, they appear to have an effect on the system somewhat similar to that of Chinese tea, and they have been introduced into Paris as a rival of that popular beverage. The drink is made by putting the leaves and stalks, in the proportion of fifteen grains to a teacupful, into cold water, boiling for about ten minutes, and then pouring into a closed vessel, and sweetening it when used. (*A. J. P.*, 1866, 441.)

ANHALONIUM. Under the name of *Pellote* there appear to be used for narcotic purposes by the natives of Mexico several cacti belonging to the genus Anhalonium. The best known of these species is the *Anhalonium lewinii*, which inhabits the valley of the Rio Grande in Mexico, has a stem reaching about half an inch above the surface of the ground, surmounted by a top composed mainly of the blunt leaves of the plant, bent around a tuft, of from half an inch to an inch in diameter, composed of short yellow-white filaments or hairs. It is this top which constitutes the *mescal button*, which is from an inch to an inch and a half in diameter, a quarter of an inch in thickness, with a convex under surface, a texture which is brittle and hard when dry, but becomes soft when moistened, a very bitter disagreeable taste, and an odor when moist which is peculiar and disagreeable, and is especially marked in the powdered drug. The flowers of the anhalonium protrude from the centre of the top as small bell-shaped blossoms, with eight outer and twelve inner segments; the former are dark green on the back; each has a long triangular transparent point, and is three-sixteenths of an inch (5 Mm.) long. The petaloid segments are spatulate, blunt, smooth-edged, and about three-sixteenths of an inch (5 Mm.) long. The fruit is an oblong berry, a quarter of an inch (6 Mm.) long, and contains about fourteen seeds of the size of a mustard-seed.

The alkaloid *anhalonine*, which seems first to have been separated from *Anhalonium lewinii* by L. Lewin in 1888, has the formula $C_{12}H_{15}NO_3$. It crystallizes in small white prisms, and is soluble in alcohol, ether, and chloroform. *Anhaline*, $C_{10}H_{17}NO$, has been extracted from *A. fissuratum*; it crystallizes in colorless stellate prisms melting at 115° C. *Pellotine*, $C_{13}H_{19}NO_3$, crystallizes in colorless, anhydrous plates melting at 110° C. (*P. J. Tr.*, 1896, 502.)

Besides anhalonine, *A. lewinii* is said to yield *mescaline*, $C_{11}H_{17}NO_3$, in white needles melting at 151° C., *anhalonidine*, $C_{12}H_{15}NO_3$, fusing at 160° C, and oily *lophophorine*, $C_{13}H_{17}NO_3$. (Schmidt, *Lehrbuch*, II., 3te Auf., 1476.)

From time immemorial the Kiowa Indians of the Rio Grande have used the mescal buttons for the purpose of producing intoxication during their re-

ligious ceremonies. Attention was first called to the peculiar cerebral action of the drug by D. W. Prentiss and Francis P. Morgan (*T. G.*, 1895); who find that from fourteen to fifteen grammes (four to five buttons) will produce a peculiar cerebral excitement attended with an extraordinary visual disturbance, characterized by an incessant flow of visions of infinite beauty, grandeur, and variety, of both color and form, often followed after a time by the seeing of monsters, grotesque faces, and gruesome shapes. During the intoxication there are dilatation of the pupil, muscular relaxation, and some slowing of the pulse. Loss of sense of time, partial anæsthesia, weakened heart's action, great muscular relaxation, wakefulness, and in some cases nausea and vomiting also have been noted, but no distinct alteration of the respiration. These results have been confirmed by several observers.

The symptoms produced by anhalonium more closely resemble the intoxication of cannabis indica than the effect of any other known drug, but are very distinct. No cases of severe poisoning by it in man are on record. In the lower animals Dr. Lewin found that the aqueous extract of the drug is a violent convulsant, increasing reflex activity and causing death by respiratory failure. The value of anhalonium as a remedial agent has not been determined. It has been used to a slight extent as a stimulant in *hypochondriases*, *neurasthenia*, *nervous headaches*, *hysteria*, *insomnia*, *angina pectoris*, and *asthmatic dyspnœa*. S. F. Landry (*T. G.*, 1888) believes it to be a very powerful cardiac and respiratory stimulant, especially useful in cases of asthma. Dr. A. Richardson attributes (with doubtful accuracy) the cure of *neuralgias*, *inflammatory rheumatism* and *gout*, and *obesity* to doses of five drops of the tincture three times a day, and believes that the drug resembles in its action a combination of strychnine and digitalis, causing a slowing of the pulse with increase of the urine.

Prentiss and Morgan give the dose of the crude drug as from seven to fifteen grains (0·5–0·97 Gm.); of the fluid extract, from ten to fifteen drops; of the 10 per cent. tincture, from one to two teaspoonfuls.

In a mass of cactus tops sent to the Pharmacological Institute of Leipzig from Mexico as pellote, experts believed that they recognized the products of *Anhalonium fissuratum*, *A. prismaticum*, *A. williamsii*, *A. lewinii*. In experiments made upon frogs anhaline was found to be almost without physiological influence; four and a half grains of the sulphate produced in a cat only vomiting, whilst one and a half grains were taken by Heffter without causing any symptoms. Pellotine was also found to be physiologically inactive; five milligrammes causing only temporary stiffness in the legs of the frog, ten milligrammes producing stiffness, heightened reflexes, strychnic-like tetanus, lasting from three to four days, ending in recovery. In man from seven-tenths to nine-tenths of a grain (0·045–0·058 Gm.) produced only temporary sleeplessness with sense of weariness. Pilcz (*Wien. Klin. Wochen.*, ix., 1896) has used pellotine as a calmative in fifty-eight cases of *insanity* in doses of from 0·02 to 0·06 Gm. About half the cases were markedly affected, sleep coming on in from half an hour to an hour and a half after the hypodermic injection and continuing through the night. No disagreeable results and no collapse occurred, although Langstein is said to have seen collapse following the dose of seven-tenths of a grain (0·04 Gm.).

From *Anhalonium jourdanianum*, L., Lewin has obtained a minute quantity of an alkaloid. (*Arch. f. Exp. Path. und Ph.*, Bd. xxxiv.)

ANILINA. *Aniline. Amidobenzene. Phenylamine.* ($C_6H_5.NH_2$.) This is an organic base obtained from coal tar or more immediately from nitrobenzene. It was first discovered by Unverdorben, in 1826, among the products of the dry distillation of indigo, and was named by him *crystalline*. Fritzsche, who obtained it afterwards from indigo by another process, seems to have been the first to give it the name of aniline, from the Portuguese word *anil* (indigo). In 1837, Runge obtained three volatile principles from coal tar, which he named *kyanol*, *leucol*, and *pyrrhol*. Of these, kyanol was afterwards found by Hofmann to be identical with aniline, and leucol has been ascertained to be the same as quinoline (chinoline). Nitrobenzene is now the source whence most of the aniline of commerce is derived. Nitrobenzene, hydrochloric acid, and iron turnings, in equal weights, are introduced into a cast-iron vessel, care being taken that the heat produced does not rise too high, when the following reactions take place: $C_6H_5.NO_2 + H_6 = C_6H_5.NH_2 + (H_2O)_2$; $C_6H_5NH_2 + HCl = C_6H_5NH_2HCl$. The semi-solid mass which soon forms consists principally of ferrous chloride and aniline hydrochlorate. This is distilled in a large cast-iron cylinder, and the distillate redistilled, the portion coming over between 175° C. (347° F.) and 190° C. (374° F.) being collected, and considered sufficiently pure for manufacturing purposes.

Properties. Pure aniline is a thin colorless fluid, of an oily appearance; but as found in commerce it is generally more or less colored, and sometimes of a deep reddish brown. It has a peculiar, not disagreeable odor, and a pungent, aromatic, burning taste; its sp. gr. is 1·020 (Hofmann), 1·028 (Fritzsche). It is not solidified at —20° C. (—4° F.), boils at 182° C. (360° F.), and its vapors are condensed unchanged. It is slightly soluble in water, but dissolves in all proportions in ether, alcohol, wood-spirit, acetone, carbon disulphide, and the oils, fixed and volatile. Though possessed of strong basic powers, it does not restore the color of reddened litmus, nor does it change turmeric. It changes, however, the violet color of dahlias to green. With the acids it forms soluble and readily crystallizable salts. It is inflammable, and absorbs oxygen from the air, becoming at first yellowish, afterwards reddish, and ultimately brown. A characteristic property is that it produces instantly a deep blue or purple color when brought into contact with chlorinated lime or other hypochlorite. Dr. Letheby has described a very delicate test for this base. If a drop of a very weak solution of the sulphate be placed on a piece of clean platinum foil, and touched with the negative pole of a galvanic battery, the solution acquires a bluish, then a violet, and ultimately a pink color. (*P. J. Tr.*, Sept. 1862, 128.) It is a derived ammonia, having the group C_6H_5 in place of a hydrogen atom of the NH_3 molecule. It is hence often called *phenyl-amine*. The chief value of aniline at present is for the coloring matters derived from it, or rather from its derivative, *rosaniline*, contained in commercial aniline oil. Beautiful reds, purples, yellows, blues, and various other tints are obtained from it. For the mode of making inks from these colors, see *Roscoe & Schorlemmer's Chemistry*, vol. iii., part 3, pp.

318, etc. The following table shows the solubilities of aniline colors in water and alcohol:

Aniline color	Per cent. soluble in water.	Per cent. soluble in alcohol.
Aurin	nearly insoluble.	40·00
Bismarck-brown	3·00	0·35
Corallin	2·00	0·50
Dahlia-blue	4·00	1·00
Eosin	2·00	1·00
Ethyl-orange	0·02	nearly insoluble.
Fuchsin	0·30	10·00
Gentian-violet	1·50	3·00
Luteolin	0·25	0·60
Magenta-red	0·20	2·50
Malachite-green	4·00	5·00
Manchester-yellow	2·00	0·15
Methylene-blue	3·00	1·50
Methyl-green	7·00	0·25
Methyl-violet	2·00	1·50
Safranin	0·60	0·40
Tropæolin OO	0·05	0·10
Vesuvin	2·00	0·20

—*Pharm. Centralh.*, 1887, 385.

Aniline-black or *nigrosin* was discovered by Wolff in 1863. As it occurs in commerce it is a salt having the composition $C_{36}H_{29}N_3HCl$; if prepared from pure aniline it is of a deep blue color; if toluidine is present, it approaches a black in direct proportion to the amount of toluidine in it; it is very soluble in water, and ten grains dissolved in one fluidounce of water make a good *nigrosin ink*, which, however, should not be exposed to too strong a light, as all aniline inks fade in time. *Böttger's test* is for detecting cotton in linens. He dips a portion of the texture in an alcoholic solution of aniline-red, then washes it with water till the washings are colorless, and puts it into a watery solution of ammonia. If cotton be present, its threads will be deprived of color, while the linen will continue of a bright rose-color. (See *A. J. P.*, Jan. 1866, 86.) Under the name of *aniline oil* a liquid is to be found in commerce which consists of a mixture of aniline, toluidine, xylidine, cumidine, and varying quantities of by-products found in the "tailings;" the boiling point ranges between 180° C. (356° F.) and 210° C. (410° F.), and the sp. gr. is also variable; it is used as a solvent for rubber, copal, etc.

Methyl-violet or *pyoktanin*, according to Liebreich, is a mixture of aniline compounds. The *pyoktaninum cæruleum* is methyl-violet, a mixture of the hydrochlorides of *penta-* and *hexa-methyl-pararosaniline*, $C_{24}H_{28}N_3Cl$ and $C_{25}H_{30}N_3Cl$, while *pyoktanin aureum* is auramine, $C_{17}H_{24}N_3OCl$, or *imido-tetramethyl-di-p-amido-diphenyl-methane*, known commercially as *auramine O*. *Apyonin*, introduced by Pettitas as an antiseptic similar to pyoktanin, is a yellow crystalline powder slightly soluble in cold water, soluble in alcohol. *Methylene-blue*, $C_{16}H_{18}N_3SCl$, or *tetra-methyl-thionine-chloride*, is a derivative of diphenylamine, occurring in dark blue or reddish-brown bronze-tinged crystals, slightly soluble in water and alcohol.

Medical Properties. The symptoms which are produced by the inhalation or ingestion of aniline are great prostration, heaviness in the head, giddiness, vomiting, violent neuralgic pains, and, if the dose have been large enough, cyanosis, coma with dilatation of the pupils, excessive perspiration, loss of reflexes and of voluntary movement, hurried weak pulse, rapid or irregular respiration, hæmoglobinuria, a peculiar discoloration of the skin, and, if the patient survive sufficiently long, jaundice with great increase in the biliary pigment of the urine. At the autopsy reported by Müller (*A. J. P.*, 1887), in a woman killed by the swallowing of about a fluidounce (29 C.c.) of aniline, the blood was chocolate brown, and gave the spectrum of methæmoglobin; the urine was free from sugar, albumen, or blood, but contained paramidophenol, and its distillations gave aniline reactions. The hæmoglobinuria is evidently connected with an extraordinary destruction of the red blood-corpuscles, for in the case reported by Dehio (*A. J. P.*, 1888), in a woman who had taken one hundred and fifty grains (9·77 Gm.) of aniline, the red blood-corpuscles fell from normal 5,000,000 per C.c. to 2,700,000 on the seventh, and 1,400,000 on the eleventh day. The globules were replaced slowly; on the eighteenth day their number was about one-third of the normal quantity.

The violent local effects which have been noticed as produced by some aniline dyes have probably been due to the presence of arsenic, which is used in the production of aniline and may remain as a contamination. Sée and Morau (*La Méd. Mod.*, 1890) believe that *safranin* and *methyl-violet* are practically free from poisonous properties; and Penzoldt, in a series of experiments, found that methyl-violet (0·05 per kilo) caused only local alterations,—viz., extensive gangrene of the skin; *malachite-green* (0·1 per kilo) caused motor paralysis and cramps, fatal on the ninth day; *trimethyl-rosaniline* (0·02 per kilo) caused similar symptoms; *Bengal-rose* (0·25 per kilo), phenyl-blue (0·1 per kilo), and methylene-blue (0·075 per kilo) caused no special symptoms.

In an elaborate research published in the *Bull. Gén. de Thérap.*, Avril, 1891, Combemale determined that in the guinea-pig the fatal dose of methyl-blue, hypodermically given, is three decigrammes per kilo in weight; and that the symptoms produced are great prostration, loss of responding to external irritants, anuria, and chocolate discoloration of the blood. For a physiological study of *fuchsine* and of *pararosaniline*, see *Lyons Thesis*, 1892, L. Dupays.

According to J. Stilling, the aniline dyes are possessed of active germicidal properties, the most active of them being the methyl-blue or violet, to which he has given the name of *pyoktanin*, certain auramines being next in rank. In Stilling's experiments, two parts of methyl-violet per thousand indefinitely prevented flour-paste, milk, butter, lard, etc., from turning sour or rancid; whilst the solution of the strength of one to four thousand was sufficient to prevent the development of bacteria of putrefaction; the staphylococcus pyogenes aureus was found to be very susceptible to the germicidal power of the methyl-violet. Penzoldt also found that contact for one month with a concentrated solution of methyl-violet, malachite-green, trimethyl-rosaniline, and phenyl-blue was sufficient to kill the anthrax-bacilli. Sée and Morau found that one part to twenty-five hundred of safranin and cyanin would destroy the organisms of diphtheria and of pus. Janicke, experimenting with the pathognomonic organisms of pus, of anthrax, of cholera, of typhus, and of pneumonia, found the activity of pyoktanin even greater than asserted by Stilling, and noticed a very remarkable difference in the susceptibility of different species of bacteria; making the further important observation that those bacteria that were most readily stained by the methyl-violet were most readily influenced by it. On the other hand, M. Valude states (*Intern.*

Med. Congress, 1890) that a contact for at least one hour in a 1 per cent. solution of pyoktanin was required to effect the same result on pathognomonic bacteria as was caused in ten minutes by 1 to 4000 corrosive sublimate. The practical value in surgery of pyoktanin has been asserted by Stilling, by Sée and Morau, by Patterson, and by numerous other surgeons, but the remedy has not come into general use. It has even been used with alleged success superficially and parenchymatously in *epithelioma* and *cancer*, but the majority of the reports are in these affections unfavorable. In *gonorrhœa*, the strength used has varied from 1 in 500 to 2 per cent.; in *ulcers*, *carbuncles*, and *cancers* it may be employed pure after free incision, or be parenchymatously injected. Stilling uses the following preparations, insisting at the same time on the great necessity of having the methyl-blue absolutely pure: 1. *Pure methyl-violet.*—To be used as powder for large wounds and ulcers. 2. *Large pencils.*—For small wounds, burns, etc. For purulent cases the blue pencil is better than the yellow, on account of its greater antiseptic property. 3. *Small pencils.*—For application to the eye, in cases of corneal ulcer, etc. 4 *Powders.*—Of 1 in 1000 strength for mild cases of conjunctivitis, and for more severe cases (blennorrhœa) of 2 per cent. strength. These can also be used as a snuff in affections of the nasal mucous membrane. 5. *Ointments.*—In strength varying from 2 per cent. to 1 in 10. 6. *Solutions.*—Used in strengths of 1 in 1000 to 1 per cent. The 1 in 1000 solution is to be employed for ordinary cases of *conjunctivitis*, *keratitis*, etc. The solutions should be filtered and kept in dark glass bottles, and changed every eight days. E. Vonder Goltz has proposed to substitute for methyl-violet a 10 per cent. alcoholic solution of aniline-red to be diluted according to needs of surgeon. (*Med. Monatsschrift*, July, 1890.)

The fact that *methylene-blue* will stain, during life, the axis-cylinders of both sensory and motor nerve fibres led Ehrlich and Leppmann (*Deutsche Med. Wochensch.*, June, 1890) to experiment with it as an analgesic in doses of from two to four grains (0·130–0·260 Gm.) internally (fifteen grains, or 0·972 Gm., a day) and one grain (0·065 Gm.) hypodermically. The urine rapidly became bluish green; or if no change in the color of the urine was apparent, warming it developed the color; the saliva and fæces were also stained. They found the analgesic properties very pronounced, but not coming on until two hours after the administration of the remedy. They also stated that they saw coloration of the nerves after the hypodermic injection. Combemale (*La Semaine Méd*, May, 1891) denies the coloration of the nerves, and believes that any analgesic effects are due to the methæmoglobinization of the blood. Gaillard and Piotrowski also deny the existence of analgesic properties in methylene-blue, and consider it of no value as an internal medicine. On the other hand, Pilliet (*La Tribune Méd.*, Oct. 1890) affirms the correctness of the observations of Ehrlich and Leppmann, both as to the action of the drug in staining the nerves and of relieving pain; and Combemale asserts that in doses of three grains (0·195 Gm.) a day the remedy is useful in *neuralgia* and *ataxic* pains. It would appear probable that methylene-blue has local analgesic effects; but that it is capable of acting as a practical analgesic when given by the mouth remains doubtful. Ehrlich and Leppmann also employed methylene-blue in *malaria*, because they had found it to stain the plasmodia, and the practice has found imitators, especially Prof. Osler, who finds that methylene-blue has a distinct action upon the specific organisms in malarial fever, but is markedly inferior to quinine.*

Methylene-blue, which, as stated, is administered internally, is a different compound from methyl-blue or pyoktanin, and the two should not be confounded.

Aniline sulphate was employed as a nervine by Drs. Fraser and Davis many years ago (*Med. Times and Gaz.*, Aug. 1865) with success, especially in the treatment of *chorea*, the dose being five grains (0·324 Gm.) three times a day, and the immediate results some headache and giddiness and staining of the mouth and nails. The practice was followed to some extent, but never gained the confidence of the profession.

ANILINE CAMPHORATE. This is a compound which has been used by Tomaselli in doses of from eight to twelve grains (0·52–0·77 Gm.) a day as an antispasmodic. (*P. J. Tr.*, June, 1887.)

ANILIPYRIN. Gilbert and Yvon have given this name to a substance obtained by the melting together of one part of acetanilid and two parts of antipyrin. Anilipyrin is stated by Gilbert and Yvon to be extremely soluble in water and to be toxically very feeble. The fatal dose for the guinea-pig is 1·8 Gm. per kilogramme. Anilipyrin has been used by its introducers as an antipyretic and analgesic in *migraine*, *neuralgia*, *rheumatism*, etc. The dose is seven and a half grains (0·5 Gm.) from two to four times a day.

ANIMÉ. *Gum Animé.* The substance known at present by the name of animé is a resin supposed to be derived from the *Hymenœa Courbaril*, a tree of South America, though this origin is denied by Hayne. According to Dr. W. Hamilton, the resin exudes from wounds in the bark, and is found also underneath the surface of the ground, between the principal roots. (*P. J. Tr.*, vi. 522.) It is in small irregular pieces, of a pale lemon-yellow color, sometimes inclining to reddish, more or less transparent, covered with a whitish powder, brittle and pulverizable, with a shining fracture, a weak but agreeable odor, and a mild, resinous taste. It softens in the mouth, adheres to the fingers when in powder, and readily melts with heat, diffusing its agreeable odor in an increased degree. It consists of two resins, one soluble, the other insoluble in cold alcohol, and of a small proportion of volatile oil. There is a variety of a darker color, less transparent, and with small cavities in the interior; in other respects resembling the preceding. Another variety is the East Indian, supposed to be derived from *Vateria Indica*; but this never reaches American commerce. According to Dr. W. C. Ondaatje, the bark of this plant is in daily use by the natives of Ceylon to arrest the alcoholic fermentation of the juice of the Jaggery palm, *Caryota urens*, a favorite beverage. (*P. J. Tr.*, 1883, 818.) Animé formerly entered into the composition of various ointments and plasters; but it is now used only as incense, or in the preparation of varnishes. The Brazilians employ it internally in *diseases of the lungs*.

ANISE BARK OIL. There has appeared in the European markets a bark, closely resembling Massoi bark, derived from an unknown source in Madagascar, which yields fully three and a half per cent. of a light yellow oil, the odor of which

* For an article upon the methods of detecting aniline in the body, see *Journ. de Pharm.*, 4e sér., xix. 341, 417.

slightly resembles safrol. It has a spicy taste, but is only slightly sweet. Its specific gravity is 0·969 at 15° C. Optical rotation —0° 46′ in a 100-Mm. tube. Refraction equivalent for the sodium line at 16° 1·52510. It contains a small quantity of ordinary anethol, but consists principally of the isomeric fluid anethol, the *methyl-chavicol* of Eykman, $CH_3O.C_6H_4.CH_2.CH:CH_2$.

ANISODUS LURIDUS. Link and Otto. (Now *Scopolia lurida*, Dun.) This is a Himalayan solanaceous plant in which Dr. Siebert has found *atropine* and *hyoscyamine*. (*Archiv der Pharm.*, Feb. 1890; *P. J. Tr.*, March, 1890.)

ANNATTO. *Orleana. Annotta. Arnotta. Terre dela Nouvelle-Orléans*, Fr. *Orellana, Orlean*, G. The coloring substance called *annatto, arnatta*, or *roucou*, is the reddish pulp surrounding the seeds in the fruit of *Bixa Orellana*, L. (nat. ord. Bixineæ), a middle-sized tree growing in Guiana and other parts of South America. The pulp is separated by bruising the fruit, mixing it with water, then straining through a sieve, and allowing the liquid to settle. The mass which remains is dried and formed into flat cakes or cylindrical rolls. Another mode is to bruise the seeds, mix them with water, and allow the mixture to ferment. The coloring matter is deposited during the fermentation, after which it is removed and dried. In commerce there are two kinds of annatto, the Spanish or Brazilian, and French; the former coming in baskets from Brazil, the latter in casks from French Guiana. The French, which is also called *flag annatto*, has a disagreeable smell, probably from having been prepared by the fermenting process; but is superior, as a dye-stuff, to the Spanish, which is without any disagreeable odor. Annatto is of a brownish-red color, usually rather soft, but hard and brittle when dry, of a dull fracture, of a sweetish peculiar odor, and a rough, saline, bitterish taste. It is inflammable, but does not melt with heat. It softens in water, to which it imparts a yellow color, but does not dissolve. Alcohol, ether, the oils, and alkaline solutions dissolve the greater part of it. It contains a peculiar coloring principle, to which M. Preisser, its discoverer, gave the name of *bixin*. This has the formula $C_{15}H_{18}O_4$, and when pure is an amorphous resinous cinnabar-red substance. It is accompanied by a yellow coloring matter, *orellin*, which has been but little studied. (Wynter Blyth, *Foods: Composition and Analysis*, 507, London, 1882.) The chief uses to which annatto is applied are for dyeing silk and cotton orange-yellow, and for coloring cheese and butter. The color, however, which it imparts to cloth is fugitive. It has been given internally as a medicine; but is not now used, and probably exercises little influence upon the system. In pharmacy it is employed to color plasters, and has occasionally been substituted for saffron. It is frequently adulterated with red ochre, powdered bricks, colcothar, farinaceous substances, chalk, calcium sulphate, turmeric, etc. The mineral substances, if present, will be left behind when the annatto is burned. (See, in reference to its adulteration, *P. J. Tr.*, xv. 199, 299, and 323; also xvi. 646.)

ANNIDALIN. This substance was proposed by Messinger and Nortmann as a substitute for iodoform. *Aristol* was originally called annidalin; the latter is probably a combination of two molecules of thymol with three atoms of iodine; in other words, a *dithymol triïodide*, whereas aristol is supposed to be *dithymol diïodide*. As a substitute for the proprietary aristol, the pure dithymol diïodide ($C_{20}H_{24}I_2O_2$ $2H_2O$) has been put upon the market under the name of *Thymol Iodide*. It appears to have the same physiological and therapeutic properties as the proprietary remedy. Annidalin is a reddish-brown powder, which may be kept for several months, at least with proper care. It is decomposed by the action of light and moisture, giving off iodine and turning yellow. It is insoluble in water, slightly soluble in alcohol, readily so in chloroform and ether. (*Journ. de Méd. de Paris*, Fév. 1890.) (See *Aristol*.)

ANONA. The seeds of *A. squamosa*, Linn., *sugar apple* of the West and East Indies, are said to be poisonous and to be used to kill lice; whilst the bark is a drastic cathartic. The seeds of *A. muriatica*, L., *A. palustris*, L., and *A. spinescens*, Mart., are employed to poison fish and to exterminate destructive insects. (*Pharm. Rev.*, Oct. 1896.)

ANTENNARIA MARGARITACEA. Hook., also Benth. and Hook. *Gnaphalium margaritaceum*, L., now commonly known as *Anaphalis margaritacea*, (L.) Benth. and Hook. *Life Everlasting.* This indigenous plant, of the nat. ord. Compositæ, has the credit, with the "eclectics," of being somewhat astringent and expectorant.

ANTHRAKOKALI. For an account of this preparation, which was introduced by Dr. Polya, see 16th ed. *U. S. D.*, p. 1711.

ANTHRAROBIN. *Anthro-arobin.* $C_6H_4\begin{Bmatrix}C(OH)\\CH\end{Bmatrix}C_6H_2(OH)_2$. This substance, which is produced from commercial alizarin by reduction, was first described by Liebermann (*Berichte d. Chem. Ges.*, 1888), and proposed as a substitute for chrysarobin. It is a yellowish-white granular powder, almost insoluble in water and acidulated solutions, sparingly soluble in chloroform and ether, and readily soluble in alcohol and weak alkaline solutions. It mixes readily with fats to form ointments. It is a powerful deoxidizing agent, which seems to be less toxic than chrysarobin, and probably equally effective in the treatment of *diseases of the skin*, it having been used by G. Behrend E. B. Bronson, Köbner, and other clinicians, with asserted advantage in those diseases for which chrysarobin is employed. Behrend recommends the following. *Solution of anthrarobin:* anthrarobin, 10 parts; borax, 8 parts; water, 80 parts. *Glycerite of anthrarobin:* anthrarobin, 10 parts; glycerin, 80 parts. (*Therap. Monatshefte*, 1888.) As a topical application, the ointment or the alcoholic solution (each 10 per cent.) may be used.

ANTHRISCUS CEREFOLIUM. Hoffm., also (L.) Hoffm. *Chærophyllum Sativum.* Lam. *Scandix Cerefolium.* Linn. *Chervil.* An annual European plant of the nat. ord. Umbelliferæ, cultivated in gardens as a pot-herb, and naturalized in Eastern and Southern Pennsylvania. It has a strong agreeable odor, especially when rubbed, and a pungent, slightly bitterish taste. These properties it owes to a volatile oil. It is said to be deobstruent, diuretic, and emmenagogue, and has been recommended by different authors in *consumption, scrofula, dropsy, cutaneous* and *scorbutic affections*, and as an external application to *swollen breasts, bruises*, and other local complaints or injuries. It is very feeble, and is used chiefly as an addition to broths.

ANTIHYDROPIN. *Pulvis Taracanæ.* The powdered Russian cockroach (*Blatta lapponica*,

Blatta orientalis) is asserted, in the dose of from ten to fifteen grains (0·648–0·972 Gm.), to be actively diuretic and useful in *dropsy*. Bogomolow (*Ph. Centralb.*, July, 1879) found in them a crystalline principle, *antihydropin*, or *taracanin*. L. Reuter (*Archiv d. Pharm.*, 868–873) affirms that the discredit into which cockroaches have fallen is due to the indifferent quality of the powdered insects in the market, and gives tests for their purity.

ANTIMONIATED HYDROGEN. H_3Sb. This is a gaseous substance, and, being taken by inhalation, should be prepared at the moment of administration. For process, see Bouchardat's *Annuaire*, 1860, 143; also *Med. Times and Gaz.*, Oct. 1865.

ANTIMONY ARSENATE. This is a heavy snow-white powder, containing 56 per cent. antimony oxide and 44 per cent. arsenic acid. It is stated that it is used in Russia as an alterative in doses of one-fiftieth of a grain (0·0013 Gm.) four times a day. (*A. J. P.*, xliv. 301.)

ANTIMONY IODIDE. *Antimonii Iodidum. Teriodide of Antimony.* (SbI_3.) According to Mr. W. Copney, of London, this iodide may be conveniently prepared by gently heating, in a Florence flask, metallic antimony and iodine, in the proportion of one atom to three. The elements combine with sudden heat and liquefaction, and, upon the withdrawal of the heat, the iodide formed solidifies, and is removed by breaking the flask. Antimony iodide, as thus prepared, forms a somewhat crystalline, foliated mass, which, when pulverized, yields a deep orange-red powder. By the action of water it is decomposed. It has been tried as an alterative in dose varying from a quarter of a grain to a grain (0·016–0·065 Gm.), given in pill.

ANTINERVIN. *Salicyl-bromanilid. Salbromalid.* This substance is said to be a mixture of ammonium bromide and salicylic acid, one part of each, with two parts of acetanilid. It has been especially commended by Maragliano as an antipyretic and antirheumatic in doses of about fifteen grains (0·9 Gm.) three or four times a day.

ANTINONNIN. According to Harz and Von Miller, this yellowish pasty compound is *Potassium Ortho-di-nitro-cresolate.* It is said to be actively germicidal, odorless, and poisonous. On account of its being very effective, non-volatile, and inexpensive, it has been highly recommended for spraying plants, etc., when attacked with mildew or other vegetable parasites: 1 to 2000 in soap solution may be used. It stains bright yellow.

ANTIRRHINUM LINARIA. Linn. (Now known as *Linaria Vulgaris*, L., or *Linaria Linaria*, (L.) Karst.) *Common Toadflax. Butter and Eggs. Ramsted. Snapdragon. Linaire commune*, Fr. *Leinkraut, Flachskraut, Löwenmaul*, G. This is a perennial herbaceous plant very common in America, Europe, and Asia. It should be collected when in flower, dried quickly, and kept excluded from the air. When fresh it has a peculiar, heavy, rather disagreeable odor, which is in a great measure dissipated by drying. The taste is herbaceous, weakly saline, bitter, and slightly acrid. This plant is said to be diuretic and cathartic, and has been used in *dropsy*, *jaundice*, and *cutaneous eruptions.* It is most conveniently employed in infusion. The fresh plant is sometimes applied, in the shape of poultice or fomentation, to *hemorrhoids;* and an ointment of the flowers has been employed for the same purpose, and also locally in diseases of the skin. The flowers are used in Germany as a yellow dye.

ANTISEPSIN. *Asepsin. Monobromacetanilid. Parabromacetanilid.* $C_6H_4Br.NH(C_2H_3O)$. This substance has been used by Cattani as an antipyretic and analgesic (*Gaz. Méd.*, Paris, 1890), but as such seems to be dangerous. Cattani affirms it to be a valuable antiseptic. Dose, from six to seven grains (0·40–0·46 Gm.). Another compound, called antisepsin (or *antiseptin*), has been exploited as *iodoboro-thymolate of zinc*, which, according to Squibb, is a mixture of zinc sulphate, boric acid, zinc iodide, and thymol. (*Pharm. Post*, 1893, 106.)

ANTISEPTOL. Under this name Yvon has lauded the *cinchonine iodsulphate* as a substitute for iodoform. It contains 50 per cent. of iodine. Yvon prepares it as follows. Twenty-five grammes of the cinchonine sulphate are dissolved in two thousand grammes of water; to this solution is added sufficient of the solution of iodine to cause a precipitate, avoiding an excess; this solution is made by dissolving ten grammes each of iodine and potassium iodide in one thousand grammes of water. The precipitate is placed on a filter and well washed with water until the washings are free from iodine, and it is then air-dried. ((*Nouv. Rem.*, July, 1890.)

ANTISPASMIN. $C_{23}H_{26}NO_8Na+3C_6H_4(OH)COONa$. In this compound 1 molecule of narcein sodium is considered to have united with 3 molecules of sodium salicylate. This white, slightly hygroscopic powder contains about 50 per cent. of narcein, and is said to have the advantage over the other narcein preparations of readily forming with water a somewhat permanent solution. According to Prof. Demme, it is a valuable hypnotic and analgesic, especially advantageous in painful *cramps.* Dose, from one-half to one grain (0·032–0·065 Gm.).

ANTITHERMIN. *Phenylhydrazin-Lævulinic acid.* $C_6H_5.N_2H{=}C(CH_3).C_3H_5O_2$. This substance, which is obtained by the action of phenylhydrazin upon acetopropionic acid, occurs in colorless crystals, insoluble in cold water, soluble in ether and hot alcohol, melting point 108° C. It was first proposed in 1887 by Nicot as an antipyretic; and it has been especially experimented upon by Drobner (*Wien. Med. Presse*, 1892, 540), who finds it very active in doses of from seven and a half to ten grains (0·48–0·647 Gm.). It produces, however, pallor, cephalic distress, excessive sweating, and other evidences of vaso-motor depression, which require great caution in its use; and not more than three grains (0·2 Gm.) should be given when there is any weakness.

ANUSOL. A proprietary suppository alleged to contain a bismuth compound of iodo-resorcin-sulphonic acid has been recommended for the treatment of hemorrhoids. Zinc oxide, resorcin, bismuth oxyiodide, balsam of Peru, and cacao butter are said to be the ingredients, (*West Drug.*, 1898, 75.)

APIUM GRAVEOLENS. L. (Nat. ord. Umbelliferæ.) *Ache, Céleri*, Fr. *Sellerie, Eppich*, G. The ordinary *celery* of the gardens is believed by some persons to possess antispasmodic properties, and has been used as a nerve stimulant. It contains apiol, although in much less quantity than does parsley.

APIUM PETROSELINUM. L. *Petroselinum. U. S.* 1870. *Persil*, Fr. *Petersilie*, G. *Prezzemolo*, It. *Petroselinum sativum.* Hoffman, *Umb.* i. t. 1, f. 2. Parsley is an umbelliferous plant having a

biennial root, with an annual, round, furrowed, jointed, erect, branching stem, about two feet in height. The radical leaves are compound, pinnated in ternaries, with the leaflets smooth, divided into three lobes, and notched at the margin. In the cauline leaves, the segments of the leaflets are linear and entire. The flowers are small, pale yellow, and disposed in terminal compound umbels, with a one- or two-leaved general involucre, and partial ones composed of six or eight leaflets. The petals are five, roundish, and inflexed at their apex. The seeds (half fruits) are small, ovate, flat on one side, convex on the other, dark green, and marked with five longitudinal ridges. They have a strong terebinthinate odor, and a warm aromatic taste.

The plant is a native of Sardinia and other parts of Southern Europe, is naturalized in salt marshes on the coast of California, and is cultivated everywhere in gardens. All parts of it contain a volatile oil, to which it owes its odor and mainly its taste, as well as its use in seasoning. This oil consists of a hydrocarbon, $C_{10}H_{16}$, and a camphor, $C_{12}H_{14}O_4$, crystallizing in white silky needles, which fuse at 30° C. (86° F.), and boil at about 300° C. (572° F.), subliming with partial decomposition. Braconnot obtained from the herb a peculiar substance, resembling pectic acid in appearance, which he named *apiin*. It is procured by boiling the herb in water, straining the liquor, and allowing it to cool. The apiin then forms a gelatinous mass, which requires only to be washed with cold water. V. Gerichten (*Ber. Chem. Ges.*, 1876, 1121) found that by repeated dissolving of this gelatinous mass in alcohol and precipitation by water it could be purified and then obtained from concentrated alcoholic solution in silky needles of the formula $C_{27}H_{32}O_{16}$. MM. Joret and Homolle found the seeds to contain a volatile oil, a crystallizable fatty matter, pectin, what they believe to be the apiin of Braconnot, chlorophyll, tannin, a coloring matter, extractive, lignin, various salts, and, in addition to these, a peculiar substance to which they gave the name of *apiol*. This is a yellowish oily liquid, not volatile, heavier than water, of a peculiar and tenacious odor distinct from that of the plant, and an acrid pungent taste. It is inflammable, insoluble in water hot or cold, very soluble in alcohol, and dissolved in all proportions by ether and chloroform. It is analogous to the fixed oils, but is not chemically modified by the alkalies. It contains no nitrogen.

According to Dr. L. Wolff (*A. J. P.*, 1877, 2), commercial apiol is merely the oleoresin: he proposes a very simple process for true apiol. Powdered parsley seed is exhausted with benzin, and the liquid is spontaneously evaporated; the residue is a mixture of fixed oil, wax, and apiol; the apiol alone being soluble in alcohol can easily be separated by repeated washings with strong alcohol; the washings evaporated over a water-bath at a gentle heat leave as a residue "true apiol." L. Ough (*Chem. and Drug.*, 1894, 17) obtains apiol by percolating freshly powdered parsley seeds with alcohol (sp. gr. 0·833), distilling the alcohol from the percolate, and separating the oily residue from the deposited waxy solid.

Ciamician and Silber (*Pharm. Post*, 1888, 391) have investigated apiol, and state that the pure substance occurs in white crystals having the composition $C_{12}H_{14}O_4$, melting at 30° C. (86° F.), and boiling at 294° C. (561·2° F.). *Isapiol*, *Apiolic Acid*, *Apiolaldehyde*, and *Apion* are decomposition products. They state that isapiol has physiological properties resembling pure apiol.

Mr. H. C. Whitney (*N. R.*, January, 1880) proposes to change the name of commercial apiol, and call it oil of parsley seed. He believes that the volatile oil of parsley seed is the active and emmenagogue principle, and obtains it by distilling the freshly powdered seed with salt water. The yield was 4·27 per cent. of an oil which corresponded closely with Joret and Homolle's apiol. Gerichten (*Berichte d. Deutsch. Chem. Ges.*, 16, 17) obtained besides the peculiar terpene, *parsley camphor*, which he thinks is alone entitled to the name of apiol. He gives its melting point at 30° C. (86° F.), boiling point 300° C. (572° F.), and sp. gr. 1·015.

Parsley root is spindle-shaped, about as thick as the finger, externally white, and marked with close annular wrinkles, internally fleshy and white, with a yellowish central portion. It has a pleasant smell, and a sweetish, slightly aromatic taste, but loses these properties by long boiling and by time. Parsley *root* in the recent state is said to be aperient and diuretic, and is occasionally used in *nephritic* and *dropsical affections*. The *juice* of the fresh herb and the *seeds* have been employed in *intermittents*. According to MM. Joret and Homolle, *apiol* produces, in the dose of about fifteen grains (0·9 Gm.), a slight cerebral excitation without unpleasant effects of any kind, and, in double or quadruple the quantity, a species of intoxication, with giddiness, morbid sights and sounds, and frontal headache. They found it to cure *intermittents;* but subsequent observations have shown that it has very little antiperiodic power. MM. Joret and Baillot commend it in *amenorrhœa* and *dysmenorrhœa*, in the dose of about four grains morning and evening; in the former affection in anticipation of the menstrual period, in the latter during its continuance. Experience has confirmed its value as an emmenagogue, but it is best used in a single dose of fifteen grains (0·9 Gm.), given in capsules, at the time of the molimen. Isapiol is said to produce headache and temporary intoxication, and to have no practical advantages over apiol.

APOLYSIN. *Apolisin. Monophenetidin Citrate.* A compound of citric acid and paraphenetidin. It is a crystalline, yellowish-white powder of peculiar odor and taste, less acid than citric acid. Its melting point is 72° C. It is soluble in cold water (1 in 25), alcohol, and glycerin, and in concentrated sulphuric acid without change of color. The solution in nitric acid turns a pale orange color. The aqueous solution is not clouded by silver nitrate, nor the acid solution by hydrogen sulphide.

Dr. R. Seifert (*Deutsch Med. Wochen.*, xxi., 1895) asserts that in the dose of from eight to twenty-four grains three or four times a day (0·5–1·5 Gm.) it is a very valuable remedy as an antipyretic in various febrile diseases, and possessed of great power as an analgesic, similar in range of usefulness to phenacetin, but free from poisonous properties or disagreeable after-effects.

AQUILEGIA VULGARIS. L. *Columbine.* A perennial herbaceous plant of the nat. ord. Ranunculaceæ, indigenous to Europe, but cultivated in our gardens as an ornamental flower. All parts of it have been medicinally employed. The root, leaves, and flowers have a disagreeable odor, and a bitterish acrid taste. From the small black shining seeds A. T. De Rochebrune (*Toxicol. Africaine*, i. 1897) has separated an alkaloid, *Aquilegine*,

in the form of long, prismatic, slightly iridescent crystals. The same investigator found that the extract of the plant produces in the lower animals symptoms very similar to those caused by aconite. At one time considered *diuretic* and diaphoretic, columbine is not at present used in practical medicine.

ARALIA (*Racine d'aralie nude*, Fr.; *Nackte Aralienwurzel*, G.). *Aralia Nudicaulis.* L. *False Sarsaparilla, Wild Sarsaparilla, Shotbush, Small Spikenard, Wild Liquorice.* (*Racine d'aralie à tige nue, Petitnard*, Fr.) This plant is an indigenous perennial, belonging to the nat. ord. Araliaceæ, having one leaf and one flower-stem, springing together from the rhizome, or from a very short smooth stalk, and seldom rising two feet in height. The leaf, which stands upon a long footstalk, is twice ternate, or once and quinate, with oblong-oval, acuminate leaflets, rounded at the base, serrate on the margin, and smooth on both surfaces. The scape or flower-stem is naked, shorter than the leaf, and terminated by three small umbels, each consisting of from twelve to thirty small yellowish or greenish flowers. The fruit consists of small round berries, about as large as those of the common elder. The plant grows throughout the United States, from Canada to the Carolinas, inhabiting shady and rocky woods, and delighting in a rich soil. It flowers in May and June. The root is horizontal, creeping, sometimes several feet in length, about as thick as the little finger, more or less twisted, of a yellowish-brown color externally, of a fragrant odor, and a warm, aromatic, sweetish taste. Alpers and Murray (*Proc. A. P. A.*, 1897, 182) found in it 3·05 per cent. of resin, 0·33 per cent. of oil, tannin, an acid, albumen, and mucilage and cellulose. *Aralia racemosa*, L. (*American Spikenard*), is distinguished by its herbaceous widely branched stem, which is furnished with leaves, whose leaflets are heart-ovate, pointed, doubly serrate, slightly downy, and also by its blackish or dark purple fruit being in very numerous umbels, and so clustered as to make a large compound panicle. Its rhizome is short, two or more inches thick, furnished with closely placed, large, nodose stem-scars, and numerous roots from one to two feet long, which are much branched below. In odor and taste it resembles *A nudicaulis*, but is more spicy. *Aralia hispida*, Vent. (*Bristly Sarsaparilla, Dwarf Elder*), closely resembles *A. nudicaulis*, but is distinguished by its larger stem, which is also bristly and leafy. Its root has been used as a diuretic in *dropsy.* (*Am. J. Med. Sci.*, xix. 117.) For microscopic description with illustrations of the root of *A. nudicaulis*, by Prof. E. S. Bastin, see *Western Druggist*, 1885, 314.

Aralia racemosa and *A. nudicaulis* have been used especially in domestic practice as a gentle stimulant diaphoretic and alterative, chiefly in *rheumatic, syphilitic*, and *cutaneous affections*, in the same manner and dose as genuine sarsaparilla. A strong decoction has proved useful as a stimulant to old *ulcers.* W. R. Monroe (*A. J. P.*, Oct. 1898) found in the rhizome of the *Aralia californica* a small amount of a pale yellow, very aromatic, volatile oil, but failed to detect saponin.

ARALIA SPINOSA. L. *Angelica-tree. Hercules' Club. Toothache-tree. Prickly Elder. Prickly Ash.* The name *prickly ash* should be dropped, as it belongs properly to *Xanthoxylum fraxineum.* The stem of this arborescent shrub is erect, simple, from eight to twelve feet high, armed with numerous prickles, and furnished near the top with very large bipinnate or tripinnate leaves, which are also prickly, and are composed of oval, pointed, slightly serrate leaflets. It terminates in an ample panicle, very much branched, and bearing numerous small hemispherical umbels, in each of which are about thirty white flowers. This species of Aralia is found most abundantly and of the largest growth in the Southern States, where it is said to sometimes attain a height of from thirty to sixty feet. It grows also in the Western States, and as far north as New York. It flourishes in low, fertile woods, and flowers in August and September. The bark, root, and berries are medicinal.

The bark (*Ecorce d'aralie épineuse*, Fr.; *Dornige Aralienrinde*, G.), as in the shops, is usually in small quills or half quills, from two or three lines to half an inch in diameter, thin, fibrous, grayish externally, and armed with prickles or the remains of them, yellowish within, of an odor somewhat aromatic, and a bitterish taste, which becomes slightly acrid on chewing, and leaves a lasting sense of pungency upon the tongue. It yields its virtues to boiling water. C. W. Elkins found in the bark starch, glucose, gum, pectin, two acrid resins, volatile oil in small quantity, and what he believed to be an uncrystallizable alkaloid. (*A. J. P.*, Aug. 1880.) L. H. Holden (*A. J. P.*, 1880, 390) found along with tannin and other ingredients a glucoside, *araliin.* J. K. Lilly (*A. J. P.*, 1882, 433) obtained the glucoside by adding ether to the alcoholic extract. The glucoside is thrown out, then dissolved in water, precipitated first with neutral lead acetate and then the filtrate with basic acetate. This precipitate decomposed with hydrogen sulphide yields the glucoside, which is recrystallized out of alcohol. Decomposed by boiling with dilute hydrochloric acid, it yields sugar and *araliretin.* The virtues of *Aralia spinosa* are those of a stimulant diaphoretic. According to Elliot, an infusion of the recent bark of the root is emetic and cathartic. The remedy is used in *chronic rheumatism* and *cutaneous eruptions;* and in some parts of the South has been employed in *syphilis.* Pursh states that a vinous or spirituous infusion of the berries is remarkable for relieving rheumatic pains; and a similar tincture is said to be employed in Virginia with advantage in violent *colic.* The pungency of this tincture has also been found useful in relieving *toothache.* The bark is best administered in decoction.

ARECA NUT. *Semen Arecæ. Betel Nut*, E. *Noix d'Arec*, Fr. *Arekanüsse, Betelnüsse*, G. The *Areca Catechu*, L., is an East India palm. The fruit, which is about the size and shape of a small egg, and of an orange-yellow color, contains the nut embedded in a fibrous, fleshy envelope, and invested with a brittle shell which adheres to the exterior flesh. The kernel, the betel nut of commerce, is of a roundish-conical shape, rather larger than a chestnut, externally of a deep brown, diversified with a fawn color, so as to present a reticular appearance, internally brownish red with whitish veins, very hard, of a feeble odor when broken, and of an astringent, somewhat acrid taste. It abounds in tannin, and contains also gallic acid, a fixed oil, gum, a little volatile oil, lignin, and various saline substances. Flückiger found that the tannic acid gives a green color turning to brown with ferric salts. (*Pharmacographia*, 671.) It yields its astringency to water; and in some parts

of Hindostan an extract is prepared from it having the appearance and properties of catechu. A red coloring matter known as *Areca red* is extracted, probably resulting from the decomposition of a tannin. It is insoluble in cold water and ether, soluble in boiling water and alkaline liquids, out of which it is precipitated by acids. E. Jahns (*Ber. d. Chem. Ges.*, 1888, 3404) has found three alkaloids in areca nut: 1. *Arecoline*, $C_8H_{13}NO_2$, identical with the *arekane* of Bombalon. 2. *Arecaine*, $C_7H_{11}NO_2$, $+ H_2O$, which occurs in permanent, colorless crystals, soluble in water, insoluble in absolute alcohol, ether, chloroform, and benzol. 3. An alkaloid which exists in such small quantities that sufficient was not obtainable for close examination. On heating arecoline with strong hydrochloric acid to 150° C. it is decomposed into methyl chloride, CH_3Cl, and *arecaidine*, $C_7H_{11}NO_2$. This latter base forms colorless plates, stable in the air, fusing at from 223° to 224° C., easily soluble in water, difficultly soluble in strong alcohol, and insoluble in ether and chloroform. Arecaidine has been shown to be *methyltetrahydronicotinic* acid, and has been made synthetically from nicotinic acid. The third alkaloid of Jahns is probably *guvacine*, $C_6H_9NO_2$, of which the methyl derivative is the base arecaidine before mentioned. *Betel leaves* from *Piper Betel*, according to D. S. Kemp (*P. J. Tr.*, xx. 759), contain two volatile oils, one heavy, sp. gr. 1·046, and the other light, sp. gr. 0·9404. Immense quantities of areca nut are consumed in the East, mixed with the leaves of the Piper Betel and with lime, forming the masticatory so well known by the name of *Betel*. The red color which this mixture imparts to the saliva and the excrements is owing to the areca nut, which is also powerfully astringent, and, by its internal use, tends to counteract the relaxation of bowels to which the heat of the climate so strongly predisposes. (See *N. R.*, 1876, 71.) Marmé affirms that arecoline resembles muscarine in its action upon the heart, and is a respiratory depressant. According to Jahns (*Bull. Gén. Thérap.*, 1889), *arecaine* is the active principle of the areca nut, and a powerful *tænicide*, resembling in its action pelletierine. It is an active poison, half a grain (0·032 Gm.) sufficing to kill a rabbit in a few moments. Its general action seems to be like that of muscarine, but it influences the respiration as well as the heart, causes tetanic convulsions, and has an extraordinary influence in increasing intestinal peristalsis. Locally applied, or when given internally, it contracts the pupils. It is believed that it will prove a valuable remedy on account of its tænicidal and vermifugal properties, and its action upon peristalsis. (*Pharm. Zeitung*, Feb. 1889.) *Arecaine* is said to resemble in its physiological action methyl-nicotinic acid.

Arecoline hydrobromate, a commercial salt, according to the experiments of Fröhner, is more powerful as a stimulant to the salivary glands than pilocarpine, and more active as a laxative than eserine. It is especially commended by veterinarians in the *colic* of horses, given subcutaneously in the dose of from 0·3 to 0·6 Gm. In human medicine it has been used in the dose of from 0·004 to 0·006 Gm. against the *tapeworm* and as a myotic. According to Lavagna (*Therap. Monat.*, 1895), the 1 per cent. solution dropped into the eye will produce violent myosis, reaching its maximum in ten and beginning to disappear in thirty minutes. Lavagna and also Bietti extol the salt as a practical remedy in *glaucoma*, in which it is even superior to eserine, although its action is less enduring.

In India the areca nut has long been used as a vermifuge, the dose being a teaspoonful of the freshly grated nut, and its value against the tapeworm has been confirmed by various European and American practitioners. The usual dose is from one to two drachms (3·9–7·8 Gm.). In this country the nut has also been used for the making of a hard charcoal, employed as a basis of tooth-powder.

ARGEMONE MEXICANA. L. *Prickly Poppy. Argémone*, Fr. *Stachelmohn*, G. An annual plant, belonging to the Papaveraceæ, growing in our Southern and Western States, Mexico, the West Indies, Brazil, and in many parts of Africa and Southern Asia. The whole plant abounds in a milky, viscid juice, which becomes yellow on exposure to the air. M. Charbonnier obtained from the plant an alkaloid, which he believes to be morphine. (*Journ. de Pharm.*, Mai, 1868, 352.) For description of plant, see 16th ed. *U. S. D.* The plant is emetic and purgative, and possesses also narcotic properties. The milky, yellowish juice, which is acrid, has been used internally in obstinate *cutaneous eruptions*, and as a local application to *warts* and *chancres*, and in *diseases of the eyes*. The flowers are stated by De Candolle to have been employed as a soporific. The seeds, which are small, round, black, and roughish, are emetic in dose of two drachms infused in a pint of water; in smaller doses they are purgative. The expressed cathartic oil may be separated by means of carbon disulphide, and it is described by M. Charbonnier as of a light yellow color, limpid, transparent, retaining its fluidity at 5° C. (41° F.), of a somewhat nauseous odor, and of a slightly acrid taste, which, however, is not very disagreeable. It is a drying oil, and is entirely soluble in 5 or 6 measures of alcohol at 32·2° C. (90° F.). According to Flückiger, it has a sp. gr. of 0·919 and dries slowly, and is not soluble in 6 parts of alcohol. The volatile fatty acids, acetic, butyric, and valerianic acids, were found by Froelich to be present. It is thought applicable to various purposes in the arts, especially to painting. M. Charbonnier found it gently cathartic in the dose of from fifteen to twenty-five drops, and emetocathartic in larger doses. (*Journ. de Pharm.*, Mai, 1868, 348.) According to Dr. W. Hamilton, the seeds unite an anodyne and soporific with the cathartic property; and, in the hands of Dr. Affleck, of Jamaica, have proved useful in flatulent *colic*, given in emulsion, in the dose of about eight grains (0·518 Gm.), repeated every half-hour till three doses are taken. (*P. J. Tr.*, xiii. 642.) Dr. Bonavia also found it useful in *colic* with constipation, and, following a practice common in Upper India, applied it very successfully, as a local remedy, in a troublesome cutaneous affection about the waist, called the *dhad*.

ARGENTAMIN. Argentamin is a solution of silver phosphate in ethylene diamine. It is a clear, strongly alkaline liquid, sp. gr. 0·97, which does not precipitate albumin. Its use in medicine was proposed in 1894 by Jean Schaeffer (*Zeitsch. f. Hyg. u. Infektions*, 1894, xvi., Bd. ii.) Hoor used it in a large number of eye cases; he asserts that it causes less pain and irritation than the silver nitrate, and penetrates deeper. He used a 5 per cent. solution in the eye from one to four times a day in the same cases as those in which silver nitrate is useful. According to Aschner (*Orv. hetil.*, 1895), it is well

borne by the posterior urethra in a strong solution, as 1 to 250; but the anterior urethra will not bear more than 1 to 2000.

ARGENTI AMMONII-CHLORIDUM. *Argentum Chlorato-ammoniatum. Silver Ammonio-chloride.* This substance is formed by saturating solution of ammonia, by the aid of heat, with silver chloride, and allowing the liquid to cool in a stoppered bottle. It crystallizes in cubes. Silver ammonio-chloride has been used in the treatment of *chorea*, *epilepsy*, and *syphilis*, and as an anthelmintic, in doses of from one-twelfth to one and a half grains (0·005–0·1 Gm.). It is very rarely employed, and is probably of little value.

ARGENTI CHLORIDUM. *Silver Chloride.* (AgCl.) This is readily prepared by adding a solution of common salt to one of silver nitrate, as long as it produces a precipitate. As first thrown down, it is a white, curdy substance, but it soon becomes discolored when exposed to the light. It is decomposed by solutions of the caustic alkalies, which convert it into oxide, but not by their carbonates. After the formation of the oxide in this way, the addition of sugar reduces it, and revives the silver. (Levol.) Silver chloride has been used in *syphilis*, *epilepsy*, *chronic dysentery* and *diarrhœa*, and other diseases in which silver nitrate has been given. The dose is from one to three grains or more (0·06–0·18 Gm.), four or five times a day.

ARGENTI CITRICUM. *Silver Citrate. Itrol.* $Ag_3C_6H_5O_7$. A dry, odorless powder, soluble with difficulty in water. This salt is recommended by Credé as an antiseptic powder which may be dusted over a wound without producing irritation, or it may be injected subcutaneously into the surrounding tissue. It has been very highly recommended by O. Werler (*Dermatolog. Zeitsch.*, Bd. cxi.) as intensely poisonous to the organism of *gonorrhœa*, and non-irritant to the urethral mucous membrane; and as further having the power of penetrating deep into this membrane. The patient is to inject in the usual manner, four times a day, a solution of a strength varying from 1 to 4000 to 1 to 8000. As the itrol solution is immediately decomposed in contact with organic material, it is essential that the syringe and vessels used be kept absolutely clean. Even in *acute gonorrhœa* it is said that no burning or disagreeable sensations are caused. Werler also commends it as a remedy in the treatment of chronic *cystitis*. Tilger and other surgeons have commended the remedy in the treatment of all forms of infected mucous membrane in saturated solution (1 to 3800).

ARGENTI FLUORIDUM. *Argentum Fluoratum. Silver Fluoride.* AgF. Lazzaro claims for this preparation great antiseptic power, but there seems to be but little clinical or experimental evidence as to its value.

ARGENTI LACTAS. *Argentum Lacticum. Silver Lactate. Actol.* $AgC_3H_5O_3$. Silver lactate was introduced by Credé on account of its great bacterial influence as a surgical germicide. It is affirmed that its injection renders an already infected wound rapidly aseptic without much irritation. It is soluble in 15 parts of water, and may be used in very strong, even saturated, solution. D. A. Tilger finds that the application of the pure powder to the curetted infected sore causes only moderate burning pain of short duration and acts most happily. (*Münch. Med. Wochen.*, 1897.) Its therapeutic properties seem to be purely local, since E. Marx found that after very large doses of it injected into animals it does not prevent the development of pathogenetic germs. It is almost certainly decomposed at the point of injection, but, unlike corrosive sublimate, it does not form an insoluble compound when brought in contact with tissues, but is able to find its way through these tissues. One gramme of it has been given hypodermically without other serious symptoms except some burning pain at the point of injection. According to Marx, a remarkable rise of temperature follows the use of it in very large doses. Actol has been used to a considerable extent in dentistry, decayed or decaying pulp being washed with a 1 to 2000 solution and then dusted with itrol.

ARGENTI QUINASEPTOLAS. *Argentol.* $C_9H_5N.OHSO_3Ag$. According to Credé, this is an extremely unstable compound, which in the presence of septic matter splits up into oxyquinoline and metallic silver. It is a yellow powder, sparingly soluble in water, and has been employed either as a dusting powder or in the form of spray, or injection, 1 to 300 to 1000, in *chancres*, *gonorrhœas*, and various other surgical infections.

ARGENTI SULPHOPHENAS. *Silver Sulphocarbolate.* $C_6H_4(OH)SO_3Ag$. A crystalline powder containing 28 per cent. of metallic silver, soluble in water; proved to undergo spontaneous decomposition, but said to be more permanent than itrol. P. Zanardi asserts that it has the antiseptic properties of the soluble silver salts and is not corrosive.

ARGENTUM SOLUBILE. *Soluble Silver.* Several allotropic modifications of silver were discovered by M. Carey Lea in 1891. One of these has been introduced into medicine because of its antiseptic characters,—viz., the bluish or greenish colloidal variety, under the name of "Soluble Silver." It can be prepared by taking a mixture of 30 Gm. ferrous sulphate dissolved in 100 C.c. of water and 36 Gm. of crystallized sodium citrate dissolved in 140 C.c. of water and pouring this mixture with stirring into 100 C.c. of a 10 per cent. silver nitrate solution. After allowing the precipitate to settle, the supernatant liquid is poured off, the precipitate dissolved in water, and again precipitated with absolute alcohol. When dried, the colloidal silver is a bluish- or green-colored mass, which dissolves in water with a deep red color, but is precipitated from its solution by the addition of salt solutions. It contains 97·2 per cent. silver. It is affirmed by Credé that soluble silver is non-poisonous and useful as an internal antiseptic medicament in various general infections, such as *septicæmia*, *tuberculosis*, *diphtheria*. He uses it especially in inunction (45 grains, 3 grammes) for the adult. Several grammes of the 1 per cent. solution may be injected hypodermically without causing pain. It is probably physiologically inert, and of no medicinal value.

ARGONIN. *Argentum Casein.* This is a white powder; neutral reaction; prepared by mixing a solution of a sodium compound of casein with silver nitrate and precipitating with alcohol. It is readily soluble in warm or albuminous water, with difficulty in cold water. A 10 per cent. solution in warm water is said to be permanent in the dark. (A. Leibrecht, *Therap. Monatssch.*, vii. 1895.) Fifteen grains of this substance contain as much silver as does one grain of the silver nitrate. It makes a neutral solution in water, and has been very highly recommended by both German and

American clinicians in the treatment of acute and chronic cases of *gonorrhœa*. Its 10 per cent. solution causes no pain in acute gonorrhœa. According, however, to the elaborate study of H. M. Christian, it is not of much service in the treatment of *posterior urethritis*. Ten cubic centimetres of a 2½ to 3 per cent. solution may in the acute stages of the disease be injected into the urethra and allowed to remain there for five minutes. A solution—0·3 ammonia, 0·6 argonin, 100 of water—is said by R. Mayer to be much more powerful than argonin itself.

ARISTOL. *Dithymoldiiodide.* $C_{20}H_{24}O_2I_2$ or $\left.\begin{matrix} C_3H_7 \\ CH_3 \end{matrix}\right\} C_6H_2(OI)$ $\left.\begin{matrix} CH_3 \\ C_3H_7 \end{matrix}\right\} C_6H_2(OI)$. This substance contains about 46 per cent. of iodine; it is believed to be the product of the condensation of two molecules of thymol and the substitution of the hydrogen in the hydroxyl group in each by iodine. It may be prepared by decomposing a solution of iodine in potassium iodide by an alcoholic solution of thymol. For process, see *A. J. P.*, 1891, 175. Aristol is a red-brown powder, insoluble in water and glycerin, slightly soluble in alcohol, and freely so in ether, chloroform, and in fixed oils. It is precipitated from ethereal solutions by alcohol. Heat must not be used in making the solution; and light decomposes aristol, which must therefore be protected from it.

Medical Properties and Uses. The therapeutic properties of aristol were first brought to the notice of the profession by Eichhoff (*Monat. für Prak. Dermat.*, 1890), who claimed that it is a non-toxic and non-irritant application, having similar local properties to iodoform, and useful in the treatment of superficial *ulcerations*, *eczema*, *psoriasis*, and various other *skin affections*. The non-poisonous properties of it have been confirmed by Neisser, Quinquaud, and Fournioux. The mode of its elimination from the system has not been thoroughly worked out, but it appears to be partially decomposed, as iodine has been found in the urine after its ingestion. Neisser found that the powder has no effect upon the lower organisms, although its ethereal solution is germicidal, probably through decomposition of the aristol. It may be used as a substitute for iodoform, but the general trend of the reports is that it is not equal in antiseptic surgery to iodoform. It is, however, considerably used, especially in affections of the membranes of the nose and larynx. It has been employed by suppository in chronic *dysentery*, three grains (0·19 Gm.) three times a day, with alleged excellent results. Nadaud claims great success in *pulmonary tuberculosis* from the hypodermic injection of from one to three C.c. daily of its 1 per cent. solution in sweet almond oil.

ARMERIA VULGARIS. Willd. (Now known as *Statice Armeria*. L.) *Maiden Pink.* (Nat. ord. Plumbaginaceæ.) This plant, found in Europe, Asia, and Western North America, is said to be an active diuretic. (*Pharmaceut. Post*, May, 1890.)

ARROW-POISONS. Up to the seventh century poisoned arrows were used in Europe in warfare, and they seem not to have disappeared from Spain until the sixteenth century, whilst poisoned daggers and poisoned swords were used even later for assassinations. The nature of the poisons employed is obscure, though it is stated that the *Veratrum album* and snake venom were used. The peregrinations of English and American travellers in Africa, and the various political changes and fermentations which have been the fruit of their discoveries,—the war with Spain and the consequent bringing of attention to the Philippine Islands,—has produced so much of general interest in the wild natives of these various remote regions that we have thought it proper to prepare for our readers a general summary of what is known in regard to the poisons used by these various natives for the killing of game and the destruction of their enemies. In doing this we have thought that a geographical arrangement might well suffice. We shall omit strophanthus and the wooraris, which have become commercial products.

So far as our knowledge goes no poisonous arrows have ever been used in North America or in Northern Asia, unless, indeed, the statements made by Kracheninikow be correct. In the second volume of his *Voyage en Sibérie* French edition, 1768, this traveller states that the roots of the plant known as *Zgate* are employed by several tribes living in the far north of Asia as an arrow-poison, and it has been suggested, probably with insufficient reason, that the plant is an anemone. We have met with no recent author who has seen this poison.

Of the ASIATIC ARROW-POISONS the most important are those which have long been used by the natives of Java and other East India islands under the names of *Upas antiar* and *Upas tieute*. The *Upas antiar* is a gum-resinous exudation obtained from the *Antiaris toxicaria*, a large tree belonging to the Urticaceæ, growing in Java, Celebes, and the neighboring islands. Like certain species of Rhus, this plant exhales an aëriform matter, which very unpleasantly affects some of those who approach it, causing eruptions upon the skin and attended with much swelling; hence the fable of the deadly upas tree. The juice is mixed with various substances to give it due consistency. Whether taken internally or introduced into the system through a wound, upas acts with extreme violence, producing vomiting, great prostration, a feeble, irregular pulse, involuntary evacuations, and convulsive movements, which are soon followed by death. Maurice Doyon found *Upas antiar* to be a powerful cardiac poison, causing in small doses rise of the arterial pressure, largely by an action upon the vaso-motor centres, but in large doses arresting the heart. (*Archiv. de Physiol.*, 1892.) Pelletier and Caventou obtained from it a glucoside, *antiarin*, crystallizable, soluble in water and alcohol, but scarcely so in ether, and of the formula $C_{14}H_{20}O_5$. For a recent elaborate study of antiarin by Kiliani, see *P. J. Tr.*, lvii. Antiarin acts directly on the cardiac muscle, diminishing the irritability of the peripheral vagus and stimulating the vaso-motor centres. It belongs to the digitalis group. According to the experiments of Stockman, antiarin is the most active of known cardiac poisons, the relative powers of strophanthin, urechitin, and antiarin being such that $\frac{1}{4800}$ gr. strophanthin, $\frac{1}{2600}$ gr. urechitin, $\frac{1}{6400}$ gr. antiarin are equivalents. H. W. Bettink claims (*Ned. Tijdschr. v. Pharm.*) that besides antiarin there are present in *Upas antiar* two other active principles, *œpain* and *toxicarine*.

The *Upas tieute* is said to be obtained from a climbing woody plant growing exclusively in Java, the *Strychnos tieute* of Leschenault. This author

states that a decoction of the bark of the root is concentrated to the consistence of a thin syrup, then mixed with onions, garlic, pepper, etc., and allowed to stand till it becomes clear. This poison produces death in violent convulsion, and strychnine is said to have been found in it. (*Amer. Journ. Med. Sci.*, 1860; *Chem. and Drug.*, 1863.)

It is very probable that different extracts are employed by different tribes in the islands of the Malay Archipelago. Dr. Braidwood (*Edinburgh Med. Journ.*, 1864) found the arrow-poison known as *Dajaksh* to be a cardiac paralyzant. It is not clear whether this is or is not the same as an arrow-poison produced in Borneo, which was recently examined by Prof. Leubuscher. (*Centralb. für Innere Med.*, Bd. xvii., 1896.) This is a blackish-brown, structureless extract, with yellowish streaks through it; it is believed by Prof. Leubuscher to contain an alkaloid which he failed to isolate. This poison produced in the lower animals great muscular relaxation, with convulsive movements and cardiac arrest in systole. It was found to have no direct effect on the respiration, the peripheral nerves, or the muscles. In the higher animals the blood-pressure was reduced even by minute doses; the action upon the heart appeared to be direct.

The arrow-poisons used by the natives of the Philippine Islands are, according to the researches of P. C. Plugge (*Archiv. d. Pharmacod.*, ii. 1896), obtained from the *Rabelaisia philippinensis*. Plugge has found it in a non-nitrogenous glucoside, *rabelaisia*. This given in very large doses produced in animals some convulsive movements, followed by profound muscular relaxation, loss of reflexes, and general paralysis, ending in death from asphyxia. On the heart it acted as an energetic stimulant, belonging to the digitalin group. In the frog 0·008 milligramme produced great cardiac excitement. (See also I. Rosenthal, *Sitzungsb. f. Physk. u. Med. Soc.*, Erlangen, 1894.)

An arrow-poison is used by the Malays, under the name of *Ipoh;* it is said to be obtained from *Derris elliptica*, or the *tuba root*, which is much used in Java as a fish-poison. It contains an active acid resin, to which the name of *derrid* has been given. Derrid appears to be one of the most powerful fish-poisons known, as one-five-millionth part stupefied gold-fish in a few moments, and killed them within half an hour. The physiological action of the principle has not been studied. (*P. J. Tr.*, vol. xxi., 1890.) Later researches seem to throw doubt upon the distinctness of Ipoh poison from Upas antiar. (See *P. J. Tr.*, 1892.)

The natives of Perak, in the Straits Settlements, use an arrow-poison stated to be a combination of aqueous extracts from the root-bark of three trees, the individual extracts being known as *ipoh aker*, *aker lampong*, and *prual*. Ipoh aker and aker lampong are believed to be obtained from undescribed species of Strychnos; extracts were prepared from the root-bark of these trees by Ralph Stockman (*Lab. Rep. Roy. Soc. Edinburgh*, vol. vi., 1897), and found to be of similar physiological power, each of them having a digitalis-like action and also a well-marked curare-like action, causing arrest of the heart in systole and loss of power in the motor nerve-endings. Prual is said to be made from the root-bark of *Coptosapelta flavescens;* in the experiments of Stockman it was found to be a violent poison, very rapidly killing the muscle at the point of inoculation, and soon involving in a fatal influence the whole muscular system, so that the animal after a large dose collapsed almost at once with diastolic cardiac arrest.

The African arrow-poisons are quite numerous. *Exuja* or *Echugin* is a blackish-brown, crumbly, odorless, and intensely bitter arrow-poison, used by the Ovambos of Southwest Africa. It is said to be yielded by an apocynaceous shrub, *Adenium boehmianum*. From it R. Bohm (*Centralb. f. d. Med. Wissensch.*, 1889) isolated the crystalline glucoside, ($C_5H_8O_2$), *echugin*, and a resinous body, *echugon*. The glucoside crystallizes in small, colorless, satiny, rhombic plates, easily soluble in water and alcohol, and insoluble in ether. It is present to about 10 per cent. in the crude substance, and is said to very closely resemble strophanthin in its physiological properties.

The arrow-poison used by the Pygmies of Central Africa has been obtained by Surgeon Parke, and is described in the *P. J. Tr.*, April, 1891. It has been found to contain two active alkaloids, *erythrophlœine* and *strychnine*.

The Sakayes, the Somangs, and the Wakamba tribes in Eastern Africa produce arrow-poisons whose relations with one another are still obscure. *Hippo*, according to Laborde, causes in the lower animals vomiting, followed by tetanic convulsions and an almost simultaneous arrest of the respiration and cardiac action. (*P. J. Tr.*, July, 1887.) *Vakamba* of Laborde (*Ibid.*) is probably the same as the *ukambin* which has been studied by H. Paschkis, who found its active principle to be a crystalline body belonging to the digitalis group, and causing in the lower animals elevated blood-pressure, fibrillary contractions of the muscles, and systolic arrest of the heart. (*Centralb. Med. Wissen.*, 1862.)

Ouabaïo is an arrow-poison used by the natives of Obok, on the Gulf of Aden, which occurs in the form of small, hard, resinous, brown balls. MM. Varigny and Langlois found that one-twelfth of a grain was sufficient to kill rabbits and guinea-pigs very quickly. After large doses arrest occurred of both heart and lungs, but after small doses death occurred by failure of respiration, the heart continuing to beat after the respiratory movements had ceased. (*Brit. Med Journ.*, 1888.)

An exceedingly bitter arrow-poison, used by the tribes who inhabit the country of Segon in the French Soudan, has been examined by Ferré and Busquet (*Archiv. de Physiol. Norm. et Path.*, vii., 1895), who find that its active principle is a crystalline glucoside which is a very powerful muscle-poison, affecting directly the heart, and producing very rapidly general paralysis, with salivation, exophthalmia, disturbance of respiration and of circulation. The first influence is to increase greatly the arterial pressure. The whole action of the poison is very similar to that of strophanthin.

The botanical sources of the rare African arrow-poisons just mentioned are unknown, and it is uncertain whether these poisons are or are not distinct from better-known African poisons. It is certain that several species of the genus Acokanthera afford several arrow-poisons to the natives of Africa. Of the four principal species, *A. schimperi* (Alph.) is found abundantly in the highlands of Abyssinia and through a great portion of Eastern Africa; *A. deflersii* (Schwf.), which resembles the last-named species closely but, according to Schweinfurth, differs in that its flowers are larger, sweet-

smelling and pure white, has been found in the neighborhood of Yemen; *A. ouabaïo* is a native of Somaliland, and *A. venenata* of South Africa. For description of these plants and microscopic examination of some of the drugs, see Engler, *Botanische Jahrbucher*, Bd. xvii.

The Wa Nyika, the Wa Gyriama, and the Wa Kamba tribes of Eastern Africa prepare vegetable arrow-poisons probably from different species of plants, although the names *ouabaïn*, *wabayo*, and *ouabaïo* seem to have been used by missionaries and others sending the extract to Europe as synonyms. One of these extracts was long since referred to the root *Acokanthera schimperi*, Benth. and Hook., a reference which has been confirmed by an examination of the leaves, flowers, and fruit by Thomas R. Fraser. (*P. J. Tr.*, July, 1895.)

In 1882 Arnaud obtained from an unidentified species of the genus Acokanthera (which he named provisionally *A. ouabaïo*), a crystalline glucoside; and in 1893 Lewin separated from the *Acokanthera deflersii* an amorphous glucoside.

The French investigator, Arnaud, gives to *ouabaïn* the formula $C_{30}H_{46}O_{12}$, and says that when injected into the stomach it is not poisonous, but when taken directly into the blood is most deadly; the one-sixty-fifth of a grain (0.00101 Gm.) being sufficient to kill a man, and acting both upon the heart and the respiratory centres. Gley states that this *ouabaïn* is a local anæsthetic, having ten times the power of cocaine; and in this he has been largely corroborated by Sailer, Lewin, and others. (*Compt.-Rend. Soc. Biol.*, ii. 1895.)

For the glucoside produced by the *Acokanthera schimperi*, Fraser proposes the name of *acokantherin*. In his experiments it crystallized from water in the form of colorless, transparent, quadrangular plates; from alcohol in needle-shaped crystals, often grouped in tufts and rosettes; had a melting point of about 186° C.; was slowly soluble in water, more so in alcohol; and yielded to Dobbin the formula of $C_{30}H_{48}O_{13}$. (See *P. J. Tr.*, lv. 1895.)

Physiologically Fraser found this glucoside to act very much like strophanthin; it is a muscle-poison, which affects directly the heart muscle and thereby causes rise of the arterial pressure. Its influence upon the blood-vessels appears to be very much less than is that of digitalin.

The term *ouabaïn* (which we believe originated with Rochebrune and Arnaud as the name of a glucoside which they separated from an unknown root of North Somaliland) has been applied to glucosides which have been obtained from various African poisons and from various species of the genus Acokanthera. The formulas given by investigators for these glucosides have been for the most part closely similar, but have varied considerably even for the glucosides obtained from the same species. The difference in the formulas are not, however, important, and the researches of Lewin in 1893 (*Virchow's Archiv*, Bd. cxxxiv.) strongly indicate that the glucosides of the North African species —that is, of *A. deflersii*, *A. ouabaïo*, and *A. schimperi*—are identical, but that the glucoside of *A. venenata* is diverse; it differing from the others chemically in not being precipitated by tannic acid, and in not producing with concentrated sulphuric acid a typical green fluorescence. It was found by Lewin when injected hypodermically to act with great rapidity in the production of violent dyspnœa and great weakness. It is from that species, *A. venenata*, Don., that the Bushmen of South Africa make an arrow-poison by pounding the bark between stones, boiling it with water, then straining and boiling the water again until a jelly is formed, into which the point of the arrow is dipped. It is said that no snake-poison is added; but it is further affirmed that under the name of *Incwadi* the Bushmen also use the bulbous plant *Buphane disticha* in poisoning their arrows.

Animal Poisons. The use of animal arrow-poisons is very uncommon, though the Choco Indians, in Colombia, South America, are said to prepare a very deadly extract by holding a tree-frog, the *Phyllobates chocœnsis*, on a stick near a fire, and scraping off the subsequent exudate from the skin. As it is asserted that an exudate can be obtained from the skin of the ordinary European toad which is a violent heart-poison, the extract employed by the Choco Indians is probably a cardiac paralyzant. Again, according to Livingstone, confirmed by Baines, some of the Bushmen prepare a poison from a cream-colored grub or caterpillar, which they term *'Nga*, said to be the first stage of the beetle *Diamphidia locusta*. The grub is gradually squeezed between the forefinger and thumb, and the colorless exudate smeared over the arrow-head. Boehm and his pupil Starcke have found this poison to be similar in its action to the snake-poisons, to be dependent for its activity upon a toxic albumose, and to be non-toxic when given by the mouth. As previously stated, it is also probable that snake venom is sometimes mixed with the various vegetable poisons used by barbarians.

ARTAR ROOT. This is a drug coming from the west coast of Africa, possibly the product of *Xanthoxylum senegalense*, D. C. (nat. ord. Rutaceæ), the leaves of which have been found in commercial specimens. Two alkaloids have been discovered in it by Giacosa and Nionari, one of which is said to resemble somewhat in its action veratrine, and to be a stimulant to the heart. (*Pharm. Centralhalle*, No. xxv., 1887.)

ARTEMISIA FRIGIDA. Willdenow. *Sierra Salvia. Colorado Mountain Sage.* (Nat. ord. Compositæ.) This Rocky Mountain plant, which is found growing in immense quantities in Western America, is said to be much used in that region as a diuretic, antiperiodic, and mildly cathartic remedy. F. A. Weiss (*A. J. P.*, 1890) found indications of a glucoside. The dose of cold infusion (℥ii to Oi) is a wineglassful three times a day. One or two drachms (3·96 or 7·8 Gm.) of the powdered leaves, or one or two fluidrachms (3·75 or 7·5 C.c.) of the fluid extract, may be administered in hot infusion every half-hour until perspiration has set in.

ARUM. The root or cormus of *Arum maculatum* is occasionally used as a medicine in Europe. Its properties closely resemble those of *A. triphyllum*. Its constituents, according to Enz, are a neutral acrid volatile principle soluble in ether, starch, gum, mucilage, sugar, lignin, albumen, saponin, fixed oil, resin, and phosphate of calcium; the fresh cormus containing 58·4 per cent. of water, 5·2 of lignin, and 27·2 of starch. (*A. J. P.*, xxxi.)

Arum triphyllum, L. *Arisæma triphyllum*, Torr. and (L.) Torr. *Gouet à trois Feuilles*, Fr. *Dreiblättriger Aron*, G. (Nat. ord. Araceæ.) The *dragon-root*, *Indian turnip*, *Jack-in-the-pulpit*, or *wake-robin*, as this plant is variously called, has a perennial root or cormus, which, early in spring, sends up a large,

ovate, acuminate, variously colored spathe, convoluted at bottom, flattened and bent over at top like a hood, and supported by an erect, round, green, or purplish scape. Within the spathe is a club-shaped spadix, green, purple, black, or variegated, rounded at the end and contracted near the base, where it is surrounded by the stamens or germs in the dicœcious plants, and by both in the monœcious, the female organs being below the male. The spathe and upper portions of the spadix gradually decay, while the germs are converted into a compact bunch of shining scarlet berries. The leaves, usually one or two in number, and upon long sheathing footstalks, are composed of three ovate acuminate leaflets, paler on their under than their upper surface, and becoming glaucous as the plant advances. There are three varieties of this species, distinguished by the color of the spathe, which in one is green, in another dark purple, and in a third white. The plant is a native of North and South America, and is common in all parts of the United States, growing in moist shady places. The corm was formerly official. This is roundish, flattened, an inch or two in diameter, covered with a brown, loose, wrinkled epidermis, and internally white, fleshy, and solid. In the recent state it has a peculiar odor, and is violently acrid. It was found by Mr. D. S. Jones, besides the acrid principle and from 10 to 17 per cent. of starch, to contain albumen, gum, sugar, extractive, lignin, and salts of potassa and lime. (*A. J. P.*, xv. 83.) The Indian turnip may be preserved fresh for a year, if buried in sand.

Both the European and American arum are, in their fresh state, violent irritants to the mucous membranes, producing when chewed insupportable burning in the mouth and throat; although, according to Dr. Bigelow, the application of the freshly bruised root to the skin, of the American species at least, does not produce local inflammation. Taken internally, this plant causes violent gastro-enteritis, which may end in death. (See *Annuaire Thérap.*, 1862.) The fresh, partially dried root has been used internally as a stimulant to the secretions, especially in *asthma*, *whooping-cough*, *chronic catarrh*, and *rheumatism*. Dose, ten grains (0·648 Gm.), two or three times a day, increased to half a drachm (1·95 Gm.).

The perfectly fresh root should not be used, and the fully dried root is inactive. The corm of the European arum contains much starch, and a farina is prepared from it, in small quantities, in the Isle of Portland, on the south coast of England, and called *Portland arrow-root*, or *Portland sago*. The root of *A. esculentum*, which abounds in starch, is much used by the natives of the Sandwich and other islands of the Pacific as an article of food, having been previously deprived of its acrimony by heat.

ASAPROL (*Calcium a-monosulphonate of β-naphtol*, $C_{10}H_6\begin{cases}OH\\SO_3\end{cases}\!\!>\!Ca$ or $C_{10}H_6\begin{cases}SO_3\\OH\end{cases}\!\!>\!Ca$) is a white powder, easily soluble in water and alcohol, and resembling salicylates in its taste. It is said to be neutral in reaction, readily soluble in alcohol and water, and not altered by heat, non-irritant, slightly toxic, well borne by the digestive tract, and rapidly eliminated by the kidneys. Asaprol was originally brought forward by A. Stackler as a germicide, antipyretic, and antirheumatic, to be used in doses of from fifteen to sixty grains (0·971–3·88 Gm.) in *rheumatism*, *typhoid fever*, etc. (*Bull. Gén. de Thérap.*, 1892.) Dujardin-Beaumetz (*Ibid.*, Jan. 1894) finds that when given by the mouth to rabbits in the dose of 0·25 gramme per kilo it has no deleterious effect, although less than one gramme per kilo proves fatal. It escapes from the kidneys in the form of *sulphuric ether-naphtol*, which is to be recognized by the dark blue coloration of the urine on the addition of ferric chloride. In acute *rheumatism*, Dujardin-Beaumetz believes that the remedy is equal to salicylates, and that it has the advantage of not producing tinnitus aurium or eruptions upon the skin. From sixty to ninety grains (4–6 Gm.) may be given daily in capsules or aqueous solution. Dr. Buck (*Therap. Wochens.*, 1897) confirms the value of asaprol in *rheumatism*. Moncorvo (*Bull. Gén. Thérap.*, March and April, 1895) recommends it in *chorea* and in *malarial diseases*. He also affirms that, used locally, it is an excellent antiseptic, hæmostatic, and cicatrizant. He uses it in the 1 to 4 per cent. solution, or as an ointment with vaseline. He even asserts that a 1 per cent. solution applied to the periglotteal region will rapidly cure *whooping-cough*.

ASARABACCA. *Asarum Europœum*, L., is an acrid, herbaceous perennial plant, of the nat. ord. Aristolochiaceæ, growing in Europe, between 37° and 60° north latitude, in woods and shady places. The root is about as thick as a goose-quill, of a grayish color, quadrangular, knotted and twisted, and sometimes furnished with radicles at each joint. It has a smell analogous to that of pepper, an acrid taste, and affords a grayish powder. The leaves, which have long footstalks, are kidney-shaped, entire, somewhat hairy, of a shining deep green color when fresh, nearly inodorous, with a taste slightly aromatic, bitter, acrid, and nauseous. According to MM. Feneulle and Lassaigne, the root contains a concrete volatile oil, a very acrid fixed oil, a yellow substance analogous to *cytisin*, starch, albumen, mucilage, citric acid, and saline matters. Gräger found in the *root* a liquid volatile oil, two concrete volatile substances called respectively *asarum-camphor* or *asaron*, and *asarite*, a peculiar bitter principle called *asarin*, tannin, extractive, resin, starch, gluten, albumen, lignin, citric acid, and various salts; in the *leaves* asarin, tannin, extractive, chlorophyll, albumen, citric acid, and lignin. Rizza and Butlerow give to *asaron* the formula $C_{12}H_{16}O_3$, and state that it melts at 59° C., boils at 296° C., has the sp. gr. 1·165 at 18° C., is inodorous, has a faintly pungent taste, is somewhat soluble in boiling water, and crystallizes on cooling in delicate needles and scales. Gräger's *asarite* is merely asaron crystallized in fine needles. (*Ber. der Chem. Ges.*, 1884, 1159.) Poleck (*Ibid.*, 1415) gives the fusing point of asaron as 61° C., and its formula as $C_8H_{10}O_2$. The active principles appear to be the volatile oil, which is lighter than water, glutinous, yellow, of an acrid and burning taste, and a smell like that of valerian, and the asarin, which is soluble in alcohol and very bitter, and is probably the same as the *cytisin* of Feneulle and Lassaigne. (See *Cytisus Laburnum.*) The volatile oil has been examined by Petersen: it consists of an oil which has the composition $C_{11}H_{14}O_2$, and is identical with the methyl ether of eugenol, and a terpene, $C_{10}H_{16}$, boiling between 162° C. (323·6° F.) and 165° C. (329° F.). (*Archiv d. Pharm.*, 1888–89, 123.) The root and leaves of asarabacca are

powerfully emetic and cathartic, in doses of from thirty grains to a drachm (1·95–3·9 Gm.), but are used almost exclusively as an errhine in *headache*, and *rheumatic affections* of the face, mouth, and throat. One or two grains (0·065 or 0·13 Gm.), snuffed up the nostrils, produce much irritation, and a copious, persistent flow of mucus.

ASARUM. *Wild Ginger*, or *Canada Snake-root. Asaret du Canada*, Fr. *Canadische Haselwurzel*, G. Under this name the U. S. Pharmacopœia formerly recognized the rhizome of the indigenous *A. Canadense*, L. (Nat. ord. Aristolochiaceæ.) This plant has a short stem, which divides before it emerges from the ground into two hairy leaf-stalks, each bearing a broad, kidney-shaped, pubescent leaf. A single flower is attached to the fork of the stem by a pubescent, pendulous peduncle; it has a deep brownish-purple, woolly, three-segmented calyx, with petals reduced to nectaries, and a six-celled capsule in fruit. For more recent botanical studies of *Asarum Canadense*, L., see *A. J. P.*, 1898, 144. It has in all its parts an aromatic odor and an aromatic slightly bitter taste, which it imparts to alcohol and hot water. The rhizome occurs in long, more or less contorted pieces, from the thickness of a straw to that of a goose-quill, brownish and wrinkled externally, whitish within, hard and brittle, and frequently furnished with short fibres. The chief constituent is the volatile oil, now largely used in perfumery. F. B. Power found in the rhizome volatile oil, resin, fat, amorphous yellow coloring matter (asarin of Gräger), uncrystallizable sugar, and a small quantity of a feebly basic principle. The volatile oil consisted of, 1, *pinene;* 2, an isomer of borneol, $C_{10}H_{16}O$, *asarol* (believed to be identical with linalool); 3, a neutral substance, $C_{12}H_{16}O_2$, *asarin*, which should not be confounded with asarum-camphor; 4, a small amount of *cœrulene*. According to Petersen, the oils of *Asarum Europæum* and *Asarum Canadense* are composed in the main of one compound, which is identical with the methyl ether of eugenol, $C_6H_3(OCH_3)_2{\cdot}C_3H_5$, a compound which had been made synthetically but not previously found in nature. Power (*Pharm. Rundschau*, 1888, 101) asserts that the oils differ in at least two respects, the oil of *A. Canadense* containing no *asarone*, *asarol*, a very fragrant body, taking its place; there are also present acetic and valerianic acids (present as linalool acetate and valerianate. *Schimmel & Co.'s Report*, April, 1897, 45.) For formulas for fluid extract, syrup, and oleoresin, see *A. J. P.*, 1876, 155. F. P. Streeper (*A. J. P.*, 1888, 6) proved that strong alcohol was the proper menstruum for the fluid extract.

The medical properties of this drug are those of a feeble aromatic. From a half to one drachm 1·95–3·9 Gm.) may be used. It is employed as an aromatic adjuvant to tonic mixtures and infusions.

ASBESTOS. This term is applied to several mineral substances which occur in long capillary crystals placed side by side, the whole producing a fibrous mass which possesses qualities that render asbestos very valuable in the arts. Asbestos is incombustible, insoluble, and a poor conductor of heat. It is usually *magnesium silicate*, or a compound of silicon, lime, and magnesium, and is found in Italy, in the Tyrol, Corsica, Savoy, in the Pyrenees, in Cornwall, Scotland, and elsewhere in Europe. Beautiful specimens occur in Canada and the United States, North Carolina and Staten Island having furnished asbestos having very long fibres. For its general properties and uses, see *Pharm. Record*, 1885, 232. In the laboratory it is used for filters, for which it is admirably adapted. (See *A. J. P.*, 1883, 37; *Pharm. Rundschau*, 1885, 252.)

ASBOLIN. Under this name Braconnot has introduced a brownish-yellow syrupy liquid, prepared from an aqueous infusion of lamp-black. Béhal and Desvignes state that it consists mainly of pyrocatechin and homopyrocatechin. It has been used in the treatment of tuberculosis.

ASCLEPIAS CURASSAVICA. *Bastard Ipecacuanha. Redhead. Blood Weed.* (Nat. ord. Asclepiadaceæ.) This is a native of the West Indies, abounding especially in Nevis and St. Kitts. Both the root and expressed juice are emetic, the former in the dose of one or two scruples (1·3 or 2·6 Gm.), the latter in that of a fluidounce (30 C.c.) or more. They are also cathartic and vermifuge in somewhat smaller doses. (*A. J. P.*, xix. 19.) For analysis, see *A. J. P.*, 1887, 347.

ASIMINA TRILOBA. Dunal, also (L.) Dunal. (Nat. ord. Anonaceæ.) J. U. and C. G. Lloyd have found in the common *pawpaw* an alkaloid *asiminine*, besides a volatile oil. (*A. J. P.*, 1886.) T. M. Fletcher failed to find an alkaloid, but gives the principal constituents as fixed oil, 3·53 per cent.; resin, 3·43 per cent.; resin insoluble in ether, 9·5 per cent.; glucose and extractive, 8 per cent. (*A. J. P.*, 1891, 476.)

ASPARAGUS OFFICINALIS. L. *Asparagus. Asperge*, Fr. *Spargel*, G. (Nat. ord. Convallariaceæ.) This well-known garden vegetable is a native of Europe. It is perennial and herbaceous. The *root*, which is inodorous, and of a weak, sweetish taste, is used in France as a diuretic, aperient, and purifier, in the form of decoction, made in the proportion of one or two ounces of the root to a quart of water. Hayne asserts that, in the dried state, it is wholly inert. In the *berries* H. Reinsch has found a large proportion of glucose and a yellowish-red coloring matter, *Spargin*. (*A. J. P.*, xlii. 371.) From the juice of the young shoots Robiquet and Vauquelin obtained a peculiar crystallizable principle, called *asparagin*, $C_4H_8N_2O_3$, which has since been found in a number of plants. (See *Althæa*.) Asparagin is said to be obtained with facility by the process of dialysis. If the thick viscid mucilage of the marshmallow (*Althæa officinalis*) be put into a dialyzer, with distilled water outside, the asparagin passes into the water, and may be obtained in crystals by evaporating the solution. (See *P. J. Tr.*, May, 1862, 572.) It might probably be obtained in the same way from an infusion of asparagus.

There is at present no sufficient reason for believing that asparagus is of value in practical medicine, nor is it more than conjecture that it has an effect upon the heart, or is actively diuretic, as has been alleged. The peculiar heavy odor which it imparts to the urine has been the chief foundation for the belief in its diuretic properties; but Nencki (*Provincial Med. Journ.*, March, 1891) appears to have demonstrated that this odor is due to the presence in the urine of *methyl-mercaptan*, a gas which is frequently produced in minute quantities in the intestines by the decomposition of proteids. A. Dedrick affirms that eight grains of asparagin caused marked reduction and irregularity of the pulse, frontal headache, and muscular weakness, lasting less than two hours. (*Virchow's Archiv*, Bd.

xciv. and xcviii.) According to Justin D. Lyle (*N. Y. Med. Journ.*, July, 1892), eating asparagus causes the urine to answer Trommer's, Fehling's, and Böttger's glycosuria tests, although sugar is not present. The effect of asparagin upon tissue-change has been studied by several physiologists, with somewhat diverse results. Weiske and his students are in accord with Zuntz in the conclusion that in herbivorous animals it reduces the destruction of albuminous material; whilst Munk, Politis, and Mauthner, experimenting upon dogs and rats, have reached the conclusion that asparagin has no influence, at least in carnivora, upon tissue-change. (*Zeitsch. f. Biologie*, x., 1892.) Asparagus may be administered internally in the form of the syrup produced from the fresh juice or from the tincture.

ASPHODELUS BULBOSUS. (Nat. ord. Liliaceæ.) Under the name of *Tsinisse*, the corm of this plant is used in the East for mucilage and the adulteration of salep powder.

ASPLENIUM. *Female Fern* is the *Polypodium Filix-fœmina* of Linn., the *Asplenium Filix-fœmina* of Bernh., the *Aspidium Filix-fœmina* of Swartz, and the *Athyrium Filix-fœmina* of Roth. It has a root analogous in character to that of the male fern (*Aspidium Filix-mas*, Sw., now *Dryopteris Filix-mas* (L.), Schott), and has been supposed to possess similar vermifuge properties. At present, however, it is not used. The vulgar name of *female fern* is also given to the *Pteris aquilina*, or *common brake*, which is said by some authors to have the property of destroying the *tape-worm*. The leaves of two species of Asplenium, *A. trichomanes*, L., or *common spleenwort*, and *A. adiantum-nigrum*, or *black spleenwort*, are mucilaginous, and have been used as substitutes for the *maidenhairs* (*Adiantum capillus veneris*, L., and *A. pedatum*, L.) as pectorals, though destitute of their aromatic flavor.

ASTER PUNICEUS. L. (Nat. ord. Compositæ.) The aromatic astringent rootlets of this indigenous plant have been employed as a stimulating diaphoretic in *rheumatic* and *catarrhal affections*.

ASTERACANTHA LONGIFOLIA. Nees. (Now known as *Hygrophila spinosa*. T. Anders.) *Ik Kirit.* (Nat. ord. Acanthaceæ.) This Indian plant is said by Dr. A. Jayesingba to be an energetic hydragogue diuretic. (*Pharm. Zeitsch. f. Russland*, Sept. 1887.)

ATHEROSPERMA MOSCHATUM. Labill. *Australian Sassafras.* (Nat. ord. Monimiaceæ.) The bark of this tree, a native of Southern Australia, is said to have been long used by the Bushmen, and later by the settlers, in *rheumatism* and in secondary *syphilis*, and has been highly commended by Greeves (*London Lancet*, 1862) in acute *bronchitis*. It has been stated that both the bark and the volatile oil are powerful poisons, and M. Zeyer (*Vierteljahrschr. f. pract. Pharm.*, x. 504) obtained from the drug an alkaloid *atherospermine* ($C_{30}H_{20}NO_5$); see also *Wittstein's Organic Constituents of Plants*, 20. The abundant volatile oil is light yellow, and has a pleasant aromatic smell and taste, resembling those of oil of sassafras. Ralph Stockman (*Lab. Rep. Royal Coll. Phys.*, vi., 1897) found it to resemble in its physiological action oil of sassafras and other allied volatile oils. He took repeatedly ten minims without any pronounced effect; and one drachm given to a rabbit caused only temporary stupor, with slowing of the respiration, but not of the pulse. Three drachms caused in the rabbit marked depression of the heart and of the respiration, coma, and death in twelve hours by asphyxia.

AVA, KAVA. This is an intoxicating liquor, made in the Sandwich Islands from the large fibrous, spongy root of the *Piper methysticum* (*Macropiper methysticum*, Miquel.). The root is grayish brown; bark very thin, internally yellowish white. A transverse section shows a number of narrow lines (woody bundles) radiating from near the centre towards the circumference, the interstitial tissue being much wider than the lines themselves. The central portion of the root is soft and cellular, with a few woody bundles anastomosing with one another, and proceeding at right angles to the radiating bundles, so as to form a net-work in the centre of the transverse section. Its odor resembles that of the meadow-sweet; its taste is slightly pungent, scarcely perceptibly bitter, and causes an increased flow of saliva. M. Gobley isolated from kava root a crystalline principle (analogous to piperin), *methysticin*, or *kavahin*, which is without odor and taste, and is probably inert (*Journ. de Pharm.*, Jan. 1860.) It possesses the formula $C_{16}H_{18}O_5$. It may be obtained in acicular crystals from a concentrated tincture. Kavahin differs from piperin and cubebin in being colored red by hydrochloric acid, the red color fading on exposure to air into a bright yellow, and in being colored by strong sulphuric acid a purplish violet, which passes into green. In 1844 Morson discovered an active principle, *kawine*. This is a greenish-yellow, strongly aromatic and acrid resin. It was again studied by Cuzaut in 1860, and by Lewin in 1886. This latter investigator separates it into two resins, of which the β-resin is greasy and of a reddish-brown color, appearing in mass almost black. This is less active than the α-resin, which is yellowish brown, has the characteristic odor of the drug, is freely soluble in alcohol, and placed upon the tongue produces a burning sensation followed by local anæsthesia. (*A. J. P.*, 1886, 450.) A volatile oil has also been found in the root. (*Journ. de Pharm.*, March, 1862.) Lavialle (*L'Union Pharm.*, Jan. 1889) claims to have obtained an alkaloid, *kavaine*, whose sulphate occurs in slightly deliquescent prismatic crystals, which are soluble in an equal part of water and sparingly soluble in alcohol. (See also *Proc. A. P. A.*, 1897, 564.)

The liqueur "kava" is a stimulant, which when in sufficient dose produces an intoxication said to differ from that ordinarily caused by alcohol, in being of a silent and drowsy nature, accompanied by incoherent dreams (the drinker not being quarrelsome or excited) and great loss of muscular power, which is due probably to the action of the kava resin upon the spinal cord. The physiological action of kava root and its resin has been especially investigated by L. Lewin (*Piper methysticum*, Berlin, 1886), and David Cerna (*T. G.*, 1891.) The phenomena which follow the hypodermic injection of the fluid extract of kava or of a solution of its resin are, anæsthesia at the point of injection, followed after absorption by general paralysis, due to a direct paralysis of the motor side of the spinal cord, the motor nerves and the muscles remaining intact. The local anæsthesia is due to a paralysis of the sensory nerve filaments, and when the resin is brought in contact with the mucous membranes there is a burning pain, followed in time by a complete loss of

sensibility, which is remarkably permanent, since Lewin found that from six to seven minims of a solution of kava injected beneath the skin produced a complete loss of sensibility in the surrounding area, which did not pass away for eight days. (*Deutsche Med. Zeitung*, Feb. 1886.) The action of the drug upon the circulation is subordinate to its nervous influence, but according to the experiments of Cerna it does stimulate the heart, although it decreases the number of pulsations by stimulating the inhibitory nerve centres. The same investigator found that at first it stimulates, afterwards depresses, and finally paralyzes the respiration, by an action upon the centres.

The insolubility and irritant action of kava resin prevent its use as a practical local anæsthetic. As long ago as 1857 kava root was employed in the treatment of *gonorrhœa*, and there is much testimony to its value both in the acute and chronic form of the disease, as well as in *vaginitis*, *leucorrhœa*, *nocturnal incontinence*, and similar conditions of the genito-urinary tract. Dose of the fluid extract, from fifteen to sixty minims (0·92–3·70 C.c.) three times a day.

AZEDARACH. *U. S.* 1880. *Pride of India. Pride of China. Common Bead Tree. Ecorce d'Azédarach, Ecorce de Margousier*, Fr. *Zedrachrinde*, G. This is the bark of the root of the *Melia azedarach*, L. (nat. ord. Meliaceæ), a beautiful tree, thirty or forty feet high, with a trunk fifteen or twenty inches in diameter. When alone, it attains less elevation, and spreads out into a capacious summit. Its leaves are large and doubly pinnate, consisting of smooth, acuminate, denticulate, dark green leaflets, disposed in pairs with an odd one at the end. The flowers are of a lilac color, delightfully fragrant, and in beautiful axillary clusters near the ends of the branches. The fruit is a round drupe, about as large as a cherry, and yellowish when ripe. This species of Melia is a native of Syria, Persia, and the north of India, and is widely cultivated. It is abundant in our Southern States. North of Virginia it does not flourish. It flowers early in the spring. "The bark is in curved pieces or quills of variable size and thickness; outer surface red-brown, with irregular, blackish longitudinal ridges; inner surface whitish or brownish, longitudinally striate; fracture more or less fibrous; upon transverse section tangentially striate, with yellowish bast-fibres; inodorous, sweetish, afterwards bitter and nauseous. If collected from old roots, the bark should be freed from the thick, rust-brown, nearly tasteless, corky layer." (*U. S.* 1880.) Jacobs (*A. J. P.*, 1879, 444) believes that the active principle is a yellowish-white resin, and that the activity of the bark resides in the liber. Hanausek (1878) states that two kinds of oil of azedarach are used in Eastern Asia,—one from the fruit and the other from the seeds; the former is used medicinally, the latter only for burning. For characters of oil, see *P. J. Tr.*, Oct. 1888.

Azadirachta Indica, A. Juss. (now *Melia Azadirachta*, L.), or *Nim Tree*, according to Broughton (*P. J. Tr.*, 1873, 992), contains a bitter amorphous resin, $C_{36}H_{50}O_{11}$, which fuses at 92° C. (197·6° F.), and a crystallized principle, melting at 175° C. (347° F.). (See also *Pharm. Rev.*, 1896, 231.) Cornish (*Indian Annals of Med. Sc.*, 4, 104) had previously announced the presence of a bitter alkaloid, to which he gave the name *margosine*, from the Portuguese name for the tree, *Margosa*.

The decoction of azedarach is affirmed to be cathartic and emetic, and in large doses narcotic; but in a number of experiments made by H. C. Wood with extracts from the dried bark and fruit, it was found impossible to poison frogs or rabbits. Robins eating of the sweetish fruit, of which they are very fond, are often rendered so far insensible as to be picked up under the tree; though they usually recover in a few hours. It has been suggested that sufficient alcohol is produced by the spontaneous fermentation of the berries to cause intoxication. Children are said to eat the fruit without inconvenience, and possibly the robins simply choke themselves with the large berries. The bark is considered in the Southern States an efficient anthelmintic. The form of decoction is usually preferred. A quart of water is boiled with four ounces of the fresh bark to a pint, of which the dose for a child is a tablespoonful every two or three hours, till it affects the stomach or bowels. Another plan is to give a dose morning and evening for several successive days, and then to administer an active cathartic. The *fresh* bark and the fruit are said to be superior as vermifuges. A fluid extract and syrup of azedarach are proposed by J. J. Miles (*A. J. P.*, Aug. 1874), the former made in the usual way with diluted alcohol, except that 6 troy-ounces of white sugar are added. The syrup is made by taking 4 fluidounces of the fluid extract, 8 fluidounces of vanilla syrup, and sufficient simple syrup to make a pint.

AZOLE. The chemical substances which Hantzsch has gathered together under the name of Azole have been the subject of considerable physiological study. As, however, so far these subjects, with the exception of antipyrin, have yielded no practical result, it is sufficient here to point out the article of Tappeiner (*Archiv f. Exper. Path. u. Pharm.*, xxxvii., 1896), which contains references to the previous articles upon the subject.

BACCHARIS CORIDIFOLIA. D. C. *Mio Mio.* This composite plant of Southeastern South America is notorious from its deadly effect upon sheep and cattle. Mr. Pedro N. Arata has isolated from it an alkaloid, *baccharine*. (*P. J. Tr.*, x. 6.)

BALANITES ROXBERGHII. The fruit of this plant is used medicinally in India. It contains a principle closely resembling *saponin*. The ripe seeds yield about 50 per cent. of a fixed oil (Zachun Oil), which is used for burning. The unripe fruit is anthelmintic and purgative.

BALATA. *Gum Chicle. Chicle. Tuno Gum. Leche de Popa. Zapota Gum.* This is the dried milky juice of the *Bully Tree*, *Mimusops Kanki*, L. (*Mimusops Balata*, Gaertn.; *Achras Balata*, Aub.; *Sapota Muelleri*, Blume), of the nat. ord. Sapotaceæ, a native of Northern South America from Mexico to Guiana. It is an oxidized hydrocarbon, containing a little resin, and is said to be midway between caoutchouc and gutta-percha in its physical properties. It is more plastic and more easily kneaded than caoutchouc, however, and it is more elastic than gutta-percha. At ordinary temperatures it is solid and horny, but softens at 49° C., and can then be moulded. When bleached it is very white. Towards solvents it behaves like gutta-percha. It is used largely in England as a substitute for and adulterant of gutta-percha. In the United States it is employed in enormous quantities as the basis of chewing gum, four mil-

lion pounds' weight, with an estimated value of one and a half million dollars, having been imported in 1895 into New York from Mexico.

BALM OF GILEAD. *Balsam of Gilead. Mecca Balsam. Balsamum Gileadense. Baume de la Mecque*, Fr. The genuine balm of Gilead is the resinous juice of *Commiphora opobalsamum*, Engl. (*Amyris Gileadensis*, Linn., *Balsamodendron Gileadense*, Kunth) (nat. ord. Burseraceæ), a small evergreen tree, growing on the Asiatic and African shores of the Red Sea. It was in high repute with the ancients, and is still esteemed by the Eastern nations as a medicine and cosmetic. In Western Europe and in this country it is seldom found in a state of purity, and its use has been entirely abandoned. It is described as a turbid, whitish, thick, gray, odorous liquid, becoming solid by exposure. It possesses no medical properties which do not exist in other balsamic or terebinthinate juices. It was formerly known as *opobalsamum;* while the dried twigs of the tree were called *xylobalsamum*, and the dried fruit, *carpobalsamum.*

BALSAM OF ST. THOMÉ. *Pan Olœo, Belam Bo.* A balsam obtained from *Santiriopsis balsamifera.* It is a resinous juice obtained by incisions in the trunk of the tree. It is used as a vulnerary and in diseases of the bladder and respiratory organs. (*Apoth. Zeit.*, 1898.)

BALSAM OF SULPHUR. *Oleum lini sulfuratum.* This name was formerly given to a substance recognized by the old Edinburgh Pharmacopœia under the name of *Oleum Sulphuratum.* The directions of the College were to boil *eight parts* of olive oil and *one part* of sublimed sulphur together, with a gentle fire, in a large iron pot, stirring them constantly till they united. The iron pot was directed to be large enough to hold three times the quantity of the materials employed, as the mixture might otherwise boil over. As the vapors which rose were apt to take fire, a lid was to be at hand to cover the pot, and thus extinguish the flame if necessary. Sulphur is soluble to a considerable extent in heated oil, from which, if the solution be saturated, it will be deposited in a crystalline state on cooling. But it is not a mere solution which this process was intended to effect. The oil was partly decomposed, and the resulting preparation was an extremely fetid, acrid, viscid, reddish-brown fluid. In order that it might be obtained, it was necessary to heat the oil to the boiling point. *Sulphurated oil*, or balsam of sulphur, was formerly thought useful in *chronic catarrh, consumption*, and other *pectoral complaints;* but inconvenience arose from its acrid properties, and its internal use was abandoned. It is sometimes applied as a stimulant to *foul ulcers.* The dose is from five to thirty drops.

BALSAM WOOD. *Palo Balsamo.* This is a South American wood, derived from an unknown tree, which is believed to contain *guaiacin*, and which yields to distillation nearly six parts of a thick viscous aromatic oil. This contains as its chief constituent a crystalline solid of alcoholic character melting at 91° C., and corresponding closely to the formula $C_{14}H_{24}O$. It has found employment in perfumery. (See Schimmel & Co., *Semi-annual Reports*, April and Oct. 1892.)

BALSAMODENDRON BERRYI. Arn. (Now *Commiphora Berryi.* Engl.) (Nat. ord. Burseraceæ.) *Mulu Kilivary.* This Indian thorn yields an abundant gum resin. (*P. J. Tr.*, Aug. 1899.)

BALSAMORRHIZA TEREBINTHACEA. The root of this plant, obtained from Idaho and Oregon, has a strong terebinthinate odor, and is used medicinally in the Western States. It contains volatile oil, fixed oil, resin, organic acid, and sugar (Herma T. Kelly, *Drug Circ.*, 1897, 32).

BALSAMUM ANTARTHRITICUM INDICUM. This oily product is said to be obtained from the wood of *Eperua falcata*, Aubl. (Nat. ord. Leguminosæ.) (*Proc. A. P. A.*, xxvii. 253; *A. J. P.*, 1880, 168.) Mr. Carl Mezger found in it free butyric acid and an acid resin. (*Archiv d. Pharm.*, 1884, 889.)

BALSAMUM TRANQUILLANS. *Baume Tranquille.* This is a preparation of some note, directed by the French Codex, and consisting essentially of olive oil holding in solution the active matters of certain narcotic and aromatic plants. The fresh plants are boiled with the oil until all their water is driven off; the oil is then expressed and poured upon the dried plants properly comminuted; and the mixture, having been allowed to stand for a month, is strained, and the oil decanted. The preparation is used externally by friction as an anodyne in local pains, but especially to relieve *earache*, a few drops being placed in the ear on a pledget of cotton. A formula for it is contained in the *Journ. de Pharm.* (Août, 1862, 121). An improved process is proposed by W. C. Bakes. (*A. J. P.*, 1862, 22.) We have still further modified this, and the formula is as follows. Take of Alcoholic Extract of Belladonna, Conium, Hyoscyamus, and Stramonium, each 30 grains; Aqueous Extract of Opium, 12 grains. Soften the extracts with one fluidounce of Boiling Water, and add four fluidounces of Olive Oil. Digest this mixture with a gentle heat until the water has been evaporated, and then strain or filter. To this add 10 minims of each of the following volatile oils: Sage, Wormwood, Lavender, Thyme, Peppermint, Rue. It should be used with care.

BAPTISIA TINCTORIA. R. Br. and (L.) R. Br. *Sophora tinctoria.* Linn. *Podalyria tinctoria.* Lam. *Wild Indigo. Indigo sauvage*, Fr. *Baptisie*, G. (Nat. ord. Leguminosæ.) This is an indigenous perennial plant, abundant throughout the Eastern United States, in woods and dry barren uplands. It is from one to three feet high, with a smooth, very branching stem, small, ternate, cuneate-obovate, bluish-green leaves, and yellow flowers, which appear in July and August, and, like the whole plant, become black when dried. The root, which is the part most highly recommended, is of a dark brown color, of a slight peculiar odor in the dried state, and of a nauseous, bitter, somewhat acrid taste. Its virtues appear to reside chiefly in the cortical portion. B. L. Smedley thought that he had found in it a peculiar alkaloid. (*A. J. P.*, July, 1862, 311.) Jno. A. Weaver has shown this to be a salt of lime. (*A. J. P.*, xliii. 251.) F. V. Greene, U.S.N., proved the presence of an alkaloid, and obtained its chloride in a crystalline condition. (*A. J. P.*, 1879, 577.) Von Schroeder (*Pharm. Post*, Oct. 1885) affirms that there are in baptisia root three active principles: a glucoside, *baptisin*, insoluble in water; a glucoside, *baptin*, soluble in water; and an alkaloid, *baptitoxine.* Of these baptisin is an indifferent, bitter substance, baptin a feeble laxative, and baptitoxine an active poison, causing at first acceleration of respiration and increase of reflex activity, and afterwards death from central paralytic

asphyxia. Plugge (*Archiv d. Pharm.*, 233, 4te Heft, 1895) finds the alkaloid of *Baptisia tinctoria* to be *cystisine*. Both the seeds and root contain the alkaloid. In large doses wild indigo is said to operate violently as an emetic and cathartic; in smaller, to produce only a mild laxative effect. Stevens has employed a decoction of the root advantageously in *epidemic dysentery*. (*N. Y. Journ. of Med.*, iv. 358.) A pale blue coloring substance has been prepared from the plant as a substitute for indigo, but is greatly inferior. Another species, *B. alba* (L.), R. Br., or *prairie indigo*, which is abundant in our northwestern prairies, is said to have similar properties, and to be sometimes used as a substitute for *B. tinctoria*.

BARBADOES NUTS. *Purging Nuts. Physic Nuts. Semen Ricini Majoris. Pignon d'Inde (des Barbades); Semence du Médicinier*, Fr. *Purgirnuss, Schwarze Brechnuss*, G. These are the seeds of the *Curcas purgans*, Adanson (now *Jatropha Curcas*, Linn.) (nat. ord. Euphorbiaceæ), growing in Brazil, the West Indies, and on the western coast of Africa. The fruit is a three-celled capsule, containing one seed in each cell, and is about the size of a walnut. The seeds are blackish, oval, about eight lines long, flat on one side, convex on the other, and the two sides present a slight longitudinal prominence. They yielded to Soubeiran fixed oil, an acrid resin, sugar, gum, a fatty acid, glutin, a free acid, and salts. The oil may be separated by expression. When fresh it is without smell or color, but becomes yellowish and slightly odorous by time. When cold it deposits a white substance, which is probably palmitin. Alcohol does not readily dissolve it. Some call it *jatropha oil*. It is colorless, odorless, of sp. gr. 0·91 at 19° C., solidifies to buttery consistence at —8° C. Bouis believed it to be the glyceride of a peculiar acid, *isocetic acid*, but it is now considered to be a mixture of palmitin and myristin. Its purging quality is, however, undoubtedly due to the presence of *ricinoleic acid*. From three to five of the *seeds*, slightly roasted and deprived of their envelope, operate actively as a cathartic, and not infrequently produce nausea and vomiting, with a sense of burning in the stomach. The *oil* purges in the dose of twelve or fifteen drops, and is analogous in its action to croton oil, though less powerful. The cake left after the expression of the oil is an acrid emeto-cathartic, operating in the dose of a few grains. Either of these substances may produce serious consequences in overdoses. The leaves of the plants are rubefacient, and the juice is said to have been usefully employed as a local remedy in piles. (*A. J. P.*, 1893, 335.)

The seeds of *Curcas multifidus* (*Jatropha multifida*, Linn.) have similar properties, and yield a similar oil. This species also grows in Brazil and the West Indies. For an account by Mr. Peckolt of the use of the latex and seeds, see *Archiv d. Pharm.*, 1887, 415. *Jatropha urens* must be excessively poisonous, as accidental contact of the wrist of a gardener in Kew with a young plant produced such symptoms that for five minutes the man was thought to be dead. (*P. J. Tr.*, April, 1872, 863.)

BARII CHLORIDUM. *U. S.* 1870. *Barium Chloride. Baryum Chloratum. Baryta Muriatica. Chlorure de Baryum*, Fr. *Chlorbarium, Chlorbaryum*, G. $BaCl_2,2H_2O$. "Take of Carbonate of Barium, in small pieces, Muriatic Acid, each, *four troyounces;* Water *a pint*. Mix the Acid with the Water, and gradually add the Carbonate of Barium. Towards the close of the effervescence apply a gentle heat, and when chemical action has ceased, filter the liquor, and evaporate so that crystals may form when it cools." *U. S.* 1870. When barium carbonate is employed for obtaining barium chloride, as in the above process, the reactions are very simple. The hydrochloric acid displaces the carbonic acid with effervescence, and forms barium chloride and water. The solution of barium chloride, thus obtained, yields crystals of the chloride by concentration and cooling. Another plan is that which procures it from the sulphate, as directed in the late Edinburgh Pharmacopœia. In this the sulphate, previously ignited and powdered, is mixed with charcoal and exposed to a low white heat, by which its constituents are deoxidized, and barium sulphide produced, the oxygen escaping in combination with the carbon as carbonic oxide and acid. The barium sulphide, after having been dissolved in water, is decomposed by the addition of hydrochloric acid; hydrogen sulphide being evolved, and barium chloride formed in solution, from which, in the usual manner, the solid salt is obtained. The reactions for these two processes are: 1. $BaCO_3 + 2HCl = BaCl_2 + H_2O + CO_2$. 2. $BaSO_4 + C_4 = BaS + (CO)_4$. 3. $BaS + 2HCl = BaCl_2 + H_2S$. Of these processes, that in which the native carbonate is used is the simplest and most convenient; but the carbonate is comparatively a rare mineral, and, as the sulphate in fine powder is a cheap article of commerce, being extensively employed for mixing with white lead, it is almost always used for obtaining barium chloride and the other barium compounds.

Barium chloride is a permanent white salt, possessing a bitter and disagreeable taste. It crystallizes in rhombic tables with bevelled edges. It dissolves in about two and a half times its weight of cold water, and in a little more than its own weight at 106° C. (222° F.), the boiling point of a saturated solution. It is scarcely soluble in absolute alcohol, but dissolves in rectified spirit. Alcohol impregnated with it burns with a yellow flame. When exposed to heat, it decrepitates and loses its water of crystallization, and at a red heat fuses. It is decomposed by the sulphates, oxalates, and tartrates, and the alkaline phosphates, borates, and carbonates; also by silver nitrate, mercuric acetate and phosphate, and lead acetate. When pure it does not deliquesce. Its solution is not affected by ammonia, which proves the absence of alumina and ferric oxide, or by hydrogen sulphide, which shows that neither copper nor lead is present.

After the whole of the barium has been precipitated by an excess of sulphuric acid, the supernatant liquid is shown to be free from lime by the non-action of sodium carbonate. Lime may be separated by the process of Dr. Wolcott Gibbs, which consists in adding to the solution of the chloride a small portion of the solution of barium hydrate, and then passing through it carbonic acid, when the whole of the lime will be thrown down as a carbonate. (Wurtz, *N. Y. Journ. of Pharm.*, i. 164.) If strontium be present, an alcoholic solution of the salt will burn with a red flame.

Medical Properties. Rabuteau found that the intravenous injection of the barium chloride produces in the dog a sudden cry, convulsions, and death, with remarkable fibrillary muscular contrac-

tions, continuing after death. M. Laborde (*Bull. de l'Acad. de Méd.*, July, 1891) has shown that when the chloride is very slowly injected, the heart-beats become slower, the pupils dilate, the animal gives a shriek, and death occurs from centric arrest of the respiration; the blood and the muscles, after death, remaining of a bright red color. Given by the mouth, it produced in the dog vomiting, choleraic diarrhœa, paresis, collapse, and death. After small doses, barium has been found by Krahmer and by J. Neumann in the liver, kidney, spleen, lungs, and nerve-centres, and especially abundant in the bones. (*Pflüger's Archiv*, Bd. xxxvi.) In a case reported by MM. Ogier and Socquet (*Annales d'Hygiène Publ.*, May, 1891) death followed in five hours the ingestion of three hundred grains (19·4 Gm.). Bardet (*La Semaine Méd.*, Dec. 1891) reports recovery after sixty grains (3·8 Gm.). Barium chloride has been employed in *sclerosis* of the nerve-centres, but is of no value. It may prove to be a useful heart stimulant, since it is asserted by Lauder Brunton, confirmed by Hobart A. Hare, that in small doses it is a rapidly acting stimulant to the heart, steadying its rhythm and increasing the volume and force of the blood thrown out by the systole. (*London Pract.*, June, 1889.) *Liquor Barii Chloridi*, U. S. P. 1870, a troyounce in three fluidounces of water, is given in five-drop (0·3 C.c.) doses.

BARII IODIDUM. *Barium Iodide. Iodure de Baryum*, Fr. *Jodbarium*, G. (BaI_2.) This compound may be formed by double decomposition, by adding native barium carbonate in powder to a boiling solution of ferrous iodide. M. Henry, Jr., obtained it by decomposing a solution of barium sulphide by a concentrated alcoholic solution of iodine. Sulphur is precipitated, which is separated by filtration, and barium iodide formed in solution, from which it is obtained in the solid state by rapid evaporation to dryness. Barium iodide crystallizes in small, colorless needles, which deliquesce slightly, and are very soluble in water. The solution promptly undergoes decomposition on exposure to the air, barium carbonate being precipitated, and iodine set free, which colors the solution. It has been used with advantage by Jahn and Lugol, as an alterative, in *scrofulous affections* and morbid growths. The dose is the eighth of a grain (0·008 Gm.) three times a day, gradually increased to three grains (0·194 Gm.).

BARII SULPHAS. *Barium Sulphate.* ($BaSO_4$.) (See *Barii Chloridum.*) Barium sulphate is a heavy, lamellar, brittle mineral, varying in sp. gr. from 4·4 to 4·6. It is generally translucent, but sometimes transparent or opaque, and its usual color is white or flesh-red. When crystallized, it is usually in very flat rhombic prisms. Before the blowpipe it strongly decrepitates, and melts into a white enamel, which, in the course of ten or twelve hours, falls to powder. It is thus partially converted into barium sulphide, and, if applied to the tongue, will give a taste like that of putrid eggs, from the formation of hydrogen sulphide. This salt, on account of its great insolubility, is not poisonous. It is, however, soluble in a great excess of dilute hydrochloric acid. (*Chem. News*, 1871, 69.) Ground to fine powder it is sometimes mixed with white lead, but impairs the quality of that pigment. The artificial barium sulphate, under the name of *permanent white* or *blanc-fixe*, is much used in the arts as a water-color. It is made from both the native sulphate and carbonate. It forms a dazzling white color, unalterable by light, heat, air, or hydrogen sulphide. It is used by the manufacturers of paper hangings, and for mixing with colors, the tone of which it does not impair.

BASSORA GALLS are cultivated in Persia and Asia Minor, and are exported by way of Smyrna for tanning purposes. They come into commerce ground and pressed into the form of bricks. They contain, on an average, 27 per cent. of tannin.

BASSORA GUM. *Caramania Gum. Hog Gum Tragacanth. Kutera Gum.* This substance came into commerce originally from the neighborhood of Bassora, on the Gulf of Persia; but is often found mixed with gum brought from other countries, and is said to be the product of the almond- and plum-trees. It is in irregular pieces, of various sizes, never very large, brown or yellow, intermediate in the degree of its transparency between gum arabic and tragacanth, inodorous, tasteless, and possessed of the property of yielding a slight sound when broken under the teeth. But a small portion of it is soluble in water, whether hot or cold. The remainder swells up considerably, though less than tragacanth, and does not, like that substance, form a gelatinous mass, as it consists of independent granules which have little cohesion. The soluble portion is pure gum or *arabin*, and, according to M. Guérin, constitutes 11·2 per cent. The insoluble portion consists of *bassorin*, associated with a small proportion of saline substances, which yield, when the gum is burnt, 5·6 per cent. of ashes. The gum is employed only to adulterate tragacanth, and for this purpose is sometimes whitened by means of white lead.

BATIATOR ROOT. The root of the *Vernonia nigritiana*, Oliver and Hiern. (nat. ord. Compositæ), a widely distributed plant of West Africa, is said to be largely used in Senegal as a febrifuge, emetic, and anti-dysenteric, resembling ipecacuanha somewhat in its therapeutic application. The plant is a composite which climbs to the height of a foot and a half, and yields a root composed of numerous fibres from twenty to thirty centimetres long, slender and grayish yellow externally, a number of which are united to form an irregular knotty rhizome, unequally spherical at the neck or crown, and covered at this point with silky hairs. The active constituent is a glucoside, *vernonin* ($C_{10}H_{24}O_7$). (Heckel and Schlagdenhauffen, *Archiv. de Physiolog. Norm. et Path.*, Aug. 1888.) This is a hygroscopic whitish powder, forming a pale yellow solution with water, and only slightly soluble in ether and in chloroform. By the absorption of 2 mols. of water it is split into a resinous body and glucose. Physiological experiments made upon frogs show vernonin to be a cardiac poison comparable to digitalin, but about twenty-four times less active; it is also said to act as a paralyzant to the motor nerve-trunks. (*P. J. Tr.*, June 30, 1888.)

BAYACURA ROOT. This is the root of a Brazilian plant, probably the *Statice Brasiliensis*, Boiss. (nat. ord. Plumbagineæ), which is used by the natives as a discutient in glandular swellings and as an astringent gargle. F. A. Dalpe (*A. J. P.*, xiv. 361) believes that he has found in it an alkaloid, *baycurine*, besides volatile oil, gum, glucose, etc. Dr. C. Symes found in it 12·5 per cent. of tannic acid. (*Newer Mat. Med.*, 51.)

BDELLIUM. This name has been given to two different gum-resins, distinguished as *Indian* and *African bdellium*. Royle was informed that the former was obtained from the *Amyris Commiphora*, Roxb. (now *Commiphora Agallocha*, Engl.) (nat. ord.

Burseraceæ), growing in India and Madagascar. The latter is said to be the product of *Heudelotia Africana*, A. Rich. (now *Commiphora Africanum*, Endl.), which grows in Senegal. According to A. Engler, the resin of *Commiphora Roxburghiana* (Stocks), Engl., is the commercial *Gugul*, or *India Bdellium*, which is employed in the East Indies as a remedy for *leprosy*, *rheumatism*, and *syphilis*. Bdellium sometimes comes mixed with gum arabic and gum senegal. It is either in small roundish pieces, of a reddish color, semi-transparent, and brittle, with a wax-like fracture, or in large irregular lumps, of a dark brownish-red color, less transparent, somewhat tenacious, and adhering to the teeth when chewed. It has an odor and taste like those of myrrh, but weaker. It is infusible and inflammable, diffusing while it burns a balsamic odor. According to Pelletier, it consists of 59 per cent. of resin, 9·2 of gum, 30·6 of bassorin, and 1·2 of volatile oil, including loss. In medical properties it is analogous to myrrh, and was formerly used for the same purposes. In Europe it is still occasionally employed in plasters. The dose is from ten to forty grains (0·648–2·59 Gm.).

BEDEGUAR. *Fungus Rosarum.* An excrescence upon the *sweetbrier* or *eglantine*, and other species of *Rosa*, produced by the puncture of insects, especially by one or more species of *Cynips*. It is of irregular shape, usually roundish, about an inch in diameter, with numerous cells containing larvæ. It is nearly odorless, of slightly astringent taste, and was formerly considered a diuretic and anthelmintic. Dose, from ten to forty grains (0·648–2·59 Gm.).

BELÆ FRUCTUS. *Bael Fruit.* Under this name the British Pharmacopœia formerly recognized the dried, half-ripe fruit of the aurantiaceous plant *Ægle marmelos*, Correa. The so-called *Bengal quince* is a rather large tree, with an erect stem, few and irregular branches, an ash-colored bark, strong, very sharp, axillary thorns, single or in pairs, leaves and large white flowers ternate. The fruit is a berry of delicious flavor, of about the size of a large orange, somewhat spherical, but flattened at the base, and depressed at the insertion of the stem, with a hard smooth shell, and from ten to fifteen cells containing besides the seeds a large quantity of exceedingly tenacious mucilage, which when dried is hard and transparent. The tree is a native of Hindostan and of Farther India. The mucilage about the seeds is applied to various purposes in the arts, on account of its viscid properties. The rind is used in dyeing. The flowers are deemed refrigerant by the native physicians. The fresh leaves yield by expression a bitterish and somewhat pungent juice, which, diluted with water, is occasionally used in the early stage of catarrhal and other fevers. The bark of the stem and root is thought to possess febrifuge properties.

The dried fruit is imported into England in vertical slices, or in broken pieces consisting of a part of the rind with the adherent pulp and seeds. The rind is about one-eighth of an inch thick, covered with a smooth pale brown or grayish epidermis, and internally, as well as the dried pulp, pale brownish orange, or cherry-red. When moistened, the pulp becomes mucilaginous. The fruit is astringent to the taste, and yields its virtues to water by maceration or decoction. Mr. Pollock found in it tannic acid, a concrete essential oil, and a vegetable acid (*Med. Times and Gaz.*, Feb. 1864), but Prof. Flückiger states that the drug does not contain any appreciable quantity of tannin.

The difficulty of obtaining bael in England is said to have led to the substitution for it of mangosteen, the fruit of *Garcinia mangostana*. This is in irregular fragments of the rind, without adhering pulp. The pieces are convex, three or four lines or more in thickness, externally covered with a smooth, deep reddish-brown, easily separable coating, and internally pale reddish brown or reddish yellow, smooth, with projecting vertical lines. (*P. J. Tr.*, May, 1867.)

Bael is employed in *diarrhœa*, *dysentery* with debility of the mucous membrane, and other diseases of the bowels with relaxation. It is much used by some practitioners in India, generally in the form of decoction, made by slowly boiling down a pint of water containing two ounces of the dried fruit to four fluidounces. Of this one or two fluidounces (30 or 60 C.c.) are given in acute cases every two or three hours, in chronic cases two or three times a day. A. C. Abraham has devised an improved formula for the liquid extract of bael. (*Year-Book of Pharmacy*, 1896, 348.) Of the fluid extract from one to two fluidrachms (3·7–7·4 C.c.), of the solid extract thirty to sixty grains (1·95–3·9 Gm.) may be given at a dose.

BENZACETIN. *Acet-amido-ethyl Salicylic Acid.* $C_6H_3\begin{cases}OC_2H_5\\NH.COCH_3\\COOH\end{cases}$. This occurs in colorless crystals, melting at 401° F. (205° C.), sparingly soluble in water. It has been recommended by Frank as an analgesic in *migraine* and other forms of *neuralgia*, and as a sedative in nervous excitement. It has been used with alleged excellent results in conjunction with caffeine, ten parts to one. Dose, from eight to fifteen grains (0·5–1 Gm.) two or three times a day, or repeated in an hour for relief.

BENZ-ANILID, $C_6H_5.NH(C_7H_5O)$, is closely related to acetanilid, containing the benzoyl radical C_7H_5O instead of the acetyl radical C_2H_3O. White, crystalline, odorless powder, practically insoluble in water. This substance has been recommended by Cahn as an antipyretic in diseases of children in doses of,—for from one to three years, one and a half to three grains (0·1–0·2 Gm.); for from four to eight years, three to six grains (0·2–0·4 Gm.). Three grammes can be given to the adult without injury. The remedy has been very little used.

BENZOIN BENZOIN (L.). Coulter. (Formerly known as *Lindera Benzoin*. Blume.) (Nat. ord. Lauraceæ.) *Laurus Benzoin*. Linn. *Spicewood. Spice-bush. Fever-bush. Wild Allspice. Laurier Benzoin*, Fr. *Benzoelorbeer*, G. An indigenous shrub, all parts of which have a spicy, agreeable flavor, strongest in the bark and berries. By warming and expression A. W. Miller obtained from the berries 50 per cent. of oily material, which, on distillation, yielded about 2 per cent. of volatile oil. The latter had a sp. gr. of 0·850, was thin, bright green, of a warm aromatic taste, and a fragrant odor. J. M. Jones found it to be of the cinnamyl series. (*Proc. A. P. A.*, xxvi. 772; also *A. J. P.*, xlv. 300; xlvii. 246.) The small branches are said to be employed in the form of infusion or decoction, by the country-people, as a vermifuge, and an agreeable drink in *low fevers;* and the bark has been used in *intermittents*. The berries, dried and

powdered, were sometimes substituted, during the Revolutionary War, for allspice. The oil is feebly aromatic. (*A. J. P.*, xlv. 300; *Ibid.*, xlvii. 246.)

BENZO-IODO-HYDRINE. *Chloro-iodo-benzoic-glycerinester.* $(C_3H_5)ClI(C_7H_5O_2.)$ A brownish-yellow, oily mass, soluble in alcohol, ether, and benzin, insoluble in glycerin. For dispensing, it is usually mixed with powdered sugar, so that the mixture contains 3¼ per cent. of benzo-iodo-hydrine, and a teaspoonful is about the equivalent of sixteen grains of potassium iodide. It is used as a substitute for potassium iodide, because of its freedom from irritating properties and from tendency to produce iodic poisoning.

BENZO-NAPHTOL. *Benzoyl-Naphtol. Benzoate of Naphtol.* $C_{10}H_7.O(C_7H_5O)$. A compound of β-naphtol and benzoic acid, made by the action of benzoyl chloride upon β-naphtol. It is a whitish crystalline powder, without taste or smell, melting at 110° C. (230° F.). It occurs in microscopical crystals, almost odorless and tasteless, nearly insoluble in water at ordinary temperatures, more soluble in alcohol, the solubility rising rapidly with the temperature, but most soluble in chloroform. "A hot alcoholic solution should not give any cherry-red coloration when an equal volume of nitric acid and a few drops of mercuric nitrate solution are added, which would indicate the presence of free β-naphtol." This substance, which was proposed by Yvon and Berlioz (*Pract.*, Dec. 1891) as especially efficacious as an intestinal antiseptic, has been reported upon by Gilbert (*La Semaine Médicale*, May, 1892), who affirms that it is of little value in *gastric fermentation*, but very valuable in *intestinal* fermentation. It is probably slowly broken up in the intestines into benzoic acid and naphtol, and the experiments made by Ewald (*Berlin. Klin. Wochen.*, 1892) indicate that it has a positive influence upon intestinal fermentation. It appears to be free from irritant properties, and to be a very useful remedy in chronic *diarrhœa*. It is best administered in small doses of from four to eight grains (0·260–0·518 Gm.), repeated frequently, in capsule; as much as seventy-five grains (4·86 Gm.) daily may be given to an adult.

BENZO-PHENONEID. *Tetra-methyl-diapsido-benzo-phenoid.* This substance, which is soluble in 100 parts of water, has been proposed by M. Galezowski as a non-irritant and efficient germicide, and local application in ulcerative diseases of mucous membranes or skin. (*Lancet*, Jan. 1891.)

BENZOSOL. *Guaiacol Benzoate.* A colorless crystalline powder, almost free from smell and taste. It melts at 59° C. (138° F.). It is prepared from guaiacol, $C_6H_4\begin{cases}OH\\OCH_3,\end{cases}$ and benzoyl chloride or benzoic acid, and has the formula $C_6H_4\begin{cases}OCH_3\ (1)\\OCO.C_6H_5\ (2).\end{cases}$ The compound is insoluble in water, difficultly soluble in hot glacial acetic acid, readily so in chloroform, ether, and hot alcohol. In the digestive tract, it soon splits up into guaiacol and benzoic acid; this decomposition occurs partially in the stomach, but chiefly in the small intestine. It is said to appear in the urine as guaiacol and benzoic acid, and their derivatives.

Benzosol was first made by Apothecary Bougartz, and highly commended by Walzer and Hughes (*Deutsch. Med. Wochen.*, 1891) as a substitute for creosote in *phthisis*, and has been used to a considerable extent by clinicians as an intestinal antiseptic in *intestinal indigestion*, *diarrhœa*, *typhoid fever*, and other conditions. It has also been used successfully in *cystitis*, and is affirmed by Piatokowski, J. Blake White, and others to be valuable in the treatment of *diabetes*. Summerbrodt has given it continuously in *phthisis* with excellent results in doses of twenty-four grains a day, and it is probable that larger amounts may be safely administered.

BENZOYL ECGONINE. This substance is made by heating cocaine in aqueous solution to decomposition. For details, see Paul, *Pharm. Journ. and Trans.*, Oct. 17, 1885, March 27, 1886; also, Skraup, *Sitzungsb. Wiener Akad.*, 1885. The reaction is $C_{16}(CH_3)H_{18}NO_4 =$ cocaine; one methyl molecule, CH_3, being replaced by one atom of hydrogen, there results $C_{16}(H).H_{18}NO_4$ or $C_9H_{14}(C_7H_5O(NO_3 =$ benzoyl ecgonine; while CH_3OH (methyl alcohol) is formed at the same time.

The physiological action of this substance has been investigated by M. R. Stockman (*Journ. Anat. and Physiology*, vol. xxi.), who finds that it acts very much as does caffeine, but less powerfully. It does not paralyze the sensory nerves.

BENZOYL-EUGENOL. *Benzeugenol*, $C_{17}H_{16}O_3$, occurs in colorless prisms or crystals, melting at 70·5° C., soluble in alcohol, ether, and chloroform, insoluble in water. It is similar in its properties and medical uses to *cinnamyl-eugenol*, $C_{19}H_{18}O_3$. Both are used as antiseptics and in the treatment of *tuberculosis*.

BENZOYL TROPEINE $(C_{15}H_{19}NO_2 + 2H_2O)$ is formed by heating tropine with benzoic and dilute hydrochloric acids to 100° C., when the benzoyl radical, C_7H_5O, derived from benzoic acid, $C_6H_5CO.OH$, replaces a hydrogen atom of the tropine, $C_8H_{15}NO$, and $C_8H_{14}(C_6H_5CO)NO$ is produced. It forms silky needles, fusing at 58° C. When deprived of water, the anhydrous base fuses at from 41°–42° C., and can be sublimed without decomposition. It has a strong basic reaction, and its salts are not very soluble.

Filehne (*Berlin. Klin. Wochen.*, vii. 1887) has found that benzoyl tropeine is a powerful local anæsthetic, also affecting the pupil and accommodation like other tropeines. He also found other benzoyl compounds to be local anæsthetics, *benzoyl methyl-triacetonalkamine* being the most powerful, *benzoyl quinine* next, *benzoyl morphine* the least.

BERBERIS. This genus belonging to the natural order Berberidaceæ comprises various shrubs having a yellow inner bark and wood, probably most of which are more or less medicinal. The bark of the root of *B. vulgaris*, L., was formerly included in the secondary list of the U. S. Pharmacopœia, under the name of *Berberis*.

Lycium, or λυκιον of the ancients, highly valued as a local application in affections of the eye and eyelids, and used for various other purposes, is supposed to be the medicine still used in India for the same affections, under the name of *rusot* or *ruswut*. This, according to Royle, is an extract from the wood or roots of different species of Berberis, as *B. Lycium*, Royle, *B. aristata*, etc., growing in Upper India, especially near Lahore. Combined with opium and alum, it is much used, and with great asserted benefit, in both *incipient* and *chronic ophthalmia*. It has been employed also by European practitioners for the same purpose. The remedy has also been used by L. W. Stewart, with highly favorable results, in the treatment of *inter-*

mittent, *remittent*, and *typhoid fevers*, *diarrhœa*, and *dyspepsia*. (*P. J. Tr.*, Dec. 1865.)

B. aquifolium, *Oregon Grape Root*, is used in the mountainous parts of Oregon, Utah, California, Colorado, Nevada, etc. The root occurs in pieces about a foot long, one-fourth of an inch thick, of a brownish exterior, but yellowish within, yielding a bright lemon-colored bitter powder. H. B. Parsons (*N. R.*, 1882, 83) found in it *berberine* and *oxyacanthine*. The percentage of the former is said to be 2·35 and of the latter 2·82. Both the berries and the roots of the *Berberis aquifolium* have been strongly recommended by various clinicians as alterative, laxative, tonic, and diuretic; very useful in chronic *syphilitic* and *scrofulous cachexia*, in *chronic skin diseases*, especially of the scaly type, in the convalescence from *malarial* and other *fevers*, and in *chronic uterine disease*. By some they are believed to have a distinct action upon the liver, and to be very valuable in *chronic hepatitis*. The dose of the fluid extract is from ten to thirty minims (0·62–1·85 C.c.), three or four times a day.

Barberry. Berberis Vulgaris. Epinevinette, *Vinettier*, *Ecorce de Racine de Berbérides*, Fr. *Fauerach*, *gemeiner Sauerdorn*, *Berberitze*, *Berberitzen-* (*Saurach*) *Wurzelrinde*, G. *Berbero*, It., Sp. This is a native of Europe, but grows wild in waste grounds in the eastern parts of New England, and is sometimes cultivated in gardens on account of its berries. It is a spreading shrub, from four to six feet or more in height, with thorny branches, a light gray bark, and a fine yellow wood. The leaves are somewhat obovate, with ciliated teeth on their edges, and upon the young shoots three-parted and spiny. The flowers, which are in drooping many-flowered racemes, have yellow entire petals, and are succeeded by oblong scarlet berries. It is a vulgar error to suppose that the vicinity of this plant is injurious to wheat. Under the name of *Berberis canadensis*, Pursh described an American plant, which grows in hilly districts, from the borders of Canada to the Carolinas, and which is characterized, according to Gray, by its repandly-toothed leaves, with the teeth less bristly-pointed, by its few-flowered racemes, its petals notched at the apex, and its oval berries. By Hooker, however, it is considered a variety of *B. vulgaris*, from which it differs only in the points mentioned. It is from one to three feet high.

The *berries* of *B. vulgaris*, which grow in loose bunches, are oblong and of a red color, have a grateful, sour, astringent taste, and contain malic and citric acids. They are refrigerant, astringent, and antiscorbutic, and are used in Europe, in the form of drink, in *febrile diseases* and *diarrhœas*. An agreeable syrup is prepared from the juice, and the berries are sometimes preserved for the table. Dr. Graeger found in the ripe fruit 15·58 per cent. of integuments and seeds, 17·20 of soluble solid constituents, and 67·22 of water. The constituents of the juice in 100 parts of fresh berries were 5·92 parts of malic acid, 4·67 of sugar, 6·61 of gum, 67·16 of water, and 0·06 of salts of potassa and lime. (*A. J. P.*, Jan. 1, 1873, 14.) The *root* and *inner bark* have been used for dyeing yellow. The bark of the root is grayish on the outside, yellow within, very bitter, and stains the saliva when chewed. Brandes found in 100 parts of the root 6·63 of bitter, yellow extractive (impure berberine), 1·55 of brown coloring matter, 0·35 of gum, 0·20 of starch, 0·10 of cerin, 0·07 of stearin, 0·03 of chlorophyll, 0·55 of a sub-resin, 55·40 of lignin, and 35·00 of water.

O. Hesse has found in barberry root four alkaloids besides berberine. The mother-liquor from berberine hydrochloride when precipitated with soda yielded to ether, besides oxyacanthine, two other alkaloids, and a fourth, which is amorphous, remaining undissolved. One of the two alkaloids in the ethereal solution crystallizes from alcohol in small tabular crystals, and is named by the author *berbamine*. It has the composition $C_{18}H_{19}NO_3 + 2H_2O$. (*Ber. d. Ch. Ges.*, 19, 3190). To a second alkaloid the name of *oxyacanthine* has been applied. It can be obtained from the mother-liquor from which the berberine hydrochloride has been separated. The liquid is treated with caustic soda, when a dark-colored precipitate is thrown down, from which ether dissolves oxyacanthine, berbamine, and an unnamed alkaloid, while another brown-colored amorphous base remains dissolved. The ethereal solution is treated with acetic acid, and the resultant acetate decomposed by sodium sulphate, when oxyacanthine sulphate is precipitated, berbamine remaining in solution. On decomposing the solution of oxyacanthine sulphate with ammonia the free alkaloid is precipitated in flocks, which, after drying at 100° C., melt at from 138°–150° C., but when crystallized from alcohol or ether it forms anhydrous needles, melting at from 208°–210° C. Its formula is given as $C_{19}H_{21}NO_3$. It is readily soluble in chloroform and benzene, but only sparingly in petroleum spirit. (*Allen*, 2d ed., vol. iii., part 2, 466.) Schmidt and Schilbach have made some interesting studies upon the salts and decomposition products of berberine. (See *Archiv d. Pharm.*, 1887, 141; *Journ. Chem. Soc.*, 1892, 641.)

Barberry is in small doses tonic, in larger ones cathartic, and was formerly given in *jaundice*. It may be useful when the influence of a gentle tonic and laxative is required. It may be used in the form of decoction.

BETAINE. This is a new alkaloid of weak basic properties which Scheibler discovered in the juice of the sugar beet. (*A. J. P.*, xli. 559.) Husemann showed it to be identical with *lycine*, and to have the composition $C_5H_{11}NO_2$. (*A. J. P.*, 1875, 209.) Liebreich also obtained it by the oxidation of choline, and called it *oxyneurine*. (*Ber. Chem. Ges.*, iv. 735.) It has been made synthetically, and its relation to choline and similar compounds established. It is now known to be *trimethyl glycocoll*, $\begin{matrix} CH_2.N(CH_3)_3 \\ | \\ COO. \end{matrix}$

BETOL. *Naphthalol. Napthosalol*, *Salinapthol*, *Salicylic-napthyl ether. Salicylate of β-naphtol.* $C_6H_4OH.COO.C_{10}H_7$. Betol occurs in white, shining crystals, is odorless and tasteless, melts at 95° C. (203° F.), and is insoluble in cold or hot water, soluble in cold alcohol with difficulty, but readily dissolves in hot alcohol (1 : 3), in ether, and in benzol. It is not decomposed by acids or alkalies in the cold, but the alkaline pancreatic fluid has the power to decompose it into β-naphtol and salicylic acid.

Betol was proposed by Sahli as a substitute for salol, on the ground of its being less disagreeable and yielding in the intestines naphtol instead of the more poisonous phenol. It contains, however, 10 per cent. less salicylic acid than does salol, and, having a much higher melting point, splits up much

less readily in the intestines; a fact which gains importance from the observation that frequently salicylic acid cannot be found in the urine after its ingestion. Sahli has given as much as one hundred and eighty grains (11·6 Gm.) in twenty-four hours. Betol may be used in *rheumatism*, and is especially commended by Kobert in ammoniacal *cystitis*. Butter of cacao will dissolve one-quarter of its weight of betol, so that suppositories or bougies are readily made.

BETONICA OFFICINALIS. *Wood Betony.* A perennial European labiate herb, feebly aromatic and astringent. Its root has been considered emetic and purgative.

BETULA ALBA. L. *Common European Birch. Bouleau*, Fr. *Birke*, G. (Nat. ord. Cupuliferæ or nat. ord. Betulaceæ.) Various parts of this tree have been applied to medical uses. The young shoots and leaves secrete a resinous substance, having acid properties, which, combined with soda, is said to produce the effects of a tonic laxative. (*Journ. de Pharm.*, xxvi. 208.) The *inner bark*, which is bitterish and astringent, has been employed in *intermittent fever*. The epidermis is separable into thin layers, which may be employed as a substitute for paper, and are applied to various economical uses. The bark contains *betulin*, or betula camphor, which Hausmann (*Ann. Ch. und Pharm.*, 182, 368) has shown to be a diatomic alcohol, as it forms a diacetate. Its formula is $C_{36}H_{60}O_3$, fusing point 258° C. When oxidized it yields *betulinic acid*, $C_{36}H_{54}O_6$, and *betulinamaric acid*, $C_{36}H_{52}O_{16}$. Submitted to dry distillation it yields an oily body of characteristic Russia leather smell. When the bark is distilled, it yields an empyreumatic oil, *Daggett, Oleum Rusci, Betulinum*, or *Muscoviticum;* a thick, brownish-black liquid, sp. gr. 0·955, having the peculiar odor of Russia leather, in the preparation of which it is employed. This oil has been found very useful as a local application in *chronic eczema* and other *skin diseases*. Its medical properties closely resemble, if they be not identical with, those of oil of cade. Dutch and German oil of birch are quite different from the Russian oil. (See *P. J. Tr.*, xv. 769.) The *leaves* of birch, which have a peculiar aromatic, agreeable odor, and a bitter taste, have been employed, in the form of infusion, in *gout*, *rheumatism*, and *dropsy*. When the stem of the tree is wounded, a saccharine *juice* flows out which is considered useful in complaints of the kidneys and bladder, and is susceptible, with yeast, of the vinous fermentation. A beer, wine, spirit, and vinegar are prepared from it in some parts of Europe. *Tinctura Rusci* is made, according to Hager, as follows. Olei Rusci 10, Alcoholis, Ætheris, āā 15, Olei Lavandulæ, Rosmarini, Rutæ, āā 0·4 parts; filter. (*A. J. P.*, 1881.)

BEZOAR. This name has been given to concretions formed in the stomach or intestines of animals, which were formerly thought to possess extraordinary medical virtues. Many varieties have been noticed; but they were all arranged in two classes, the *oriental bezoar* (*lapis bezoar orientalis*), and the *western bezoar* (*lapis bezoar occidentalis*), of which the former was most esteemed.

BICHETIA OFFICINALIS. *Mureré Juice* is extracted in Brazil from the incised bark of this plant; it is a thick reddish liquid, sp. gr. 1·100, and is said to contain an alkaloid and to be useful in *rheumatism* and *syphilis*. The dose of the juice is one fluidrachm in water; in large doses it is drastic.

BIDENS BIPINNATA. L. *Spanish Needles.* An indigenous composite plant, of which the root and seeds are popularly used as emmenagogues, and by the "eclectics" in laryngeal and bronchial diseases as expectorants.

BIRD-LIME. *Bird-glue. Vogelleim*, G. A viscid substance, existing in various plants, particularly in the bark of *Viscum album* and *Ilex aquifolium* or *European holly*, from the latter of which it is usually procured. The process for preparing it consists in boiling the middle bark for some hours in water, then separating it from the liquid, and placing it in proper vessels in a cool situation, where it is allowed to remain till it thickens, when it is washed to separate impurities. Bird-lime thus prepared is greenish, tenacious, glutinous, bitterish, and of an odor analogous to that of flaxseed oil. Exposed to the air in thin layers it becomes dry, brown, and pulverizable, but reacquires its viscidity upon the addition of water. It is a complex body, but is thought to owe its characteristic properties to a proximate principle, which is called *glu* by the French chemists. This principle is without odor or taste, extremely adhesive, fusible by heat, inflammable, insoluble in water, nearly insoluble in alcohol, but dissolved freely by ether and oil of turpentine. According to M. Macaire, it is insoluble in the fixed oils, either hot or cold; a property which distinguishes it from the resins. M. Macaire proposes for it the name of *viscin*. (*Journ. de Pharm.*, xx. 18.) Its analysis corresponds to the formula $C_{20}H_{48}O_8$ (or possibly $C_{20}H_{32} + 8H_2O$). After the extraction of the viscin by ether, Reinsch found a substance soluble in oil of turpentine which he called *viscaoutchin*, because of its elastic caoutchouc-like character. He gives it the formula $C_8H_{16}O$. Bird-lime is so tenacious that it may be employed to catch small birds, which, when they alight on a stick thickly covered with it, are unable to escape.

BISMAL. $3Bi(OH)_3+4C_{15}H_{12}O_{10}$. The bismuth salt of methylene-digallic acid. It is used as an astringent in *diarrhœa*. Dose, from one and a half to five grains (0·1–0·32 Gm.).

BISMUTAN. *Isutan.* A yellow, odorless powder, consisting of bismuth, resorcin, and tannin. It is recommended for *intestinal catarrh* in doses for adults of from eight to fifteen grains (0·5–1 Gm.).

BISMUTH AND POTASSIUM IODIDE. This salt has been proposed as a test for the alkaloids, but it seems to offer few advantages. For preparation and use, see *A. J. P.*, xlvii. 374.

BISMUTH-CERIUM SALICYLATE is a reddish-white powder, insoluble in water and alcohol. This salt has been highly commended in *diarrhœa*, *enteritis*, and *dysentery* by Salaya. Dose, five grains (0·32 Gm.).

BISMUTHI BENZOAS. $BiO.(C_7H_5O_2)$. Basic *Bismuth Benzoate* is official in the French Codex. It is a white powder, insoluble in water, which was originally proposed by M. P. Vigier as a substitute for the bismuth salicylate; it may be made by double decomposition between bismuth nitrate and sodium benzoate; like that salt, being decomposed in the alimentary canal, benzoic acid is set free. It contains about 65 per cent. of bismuth, and may be given as an intestinal antiseptic in *diarrhœas*, in doses of from eight to fifteen grains (0·5–0·97 Gm.) four to six times a day. The benzoate has been commended by Finger as a substitute for iodoform.

It may be made by adding a solution (prepared with heat) of 76 parts of sodium benzoate in 200 parts of distilled water to a solution of 100 parts of bismuth nitrate in 20 parts of glycerin and 60 parts of distilled water. It contains 27 per cent. of benzoic acid.

BISMUTHI BORAS. $BiBO_3$. *Bismuth Borate* is a grayish-white powder which has been used as an intestinal antiseptic in doses of from seven to fifteen grains (0·5–1 Gm.).

BISMUTHI BOROPHENAS. *Markasol. Bismuth Borophenate* ($Bi_2O_3B(C_6H_5)(CO_3)3H_2O$) has been recommended as a slightly astringent absorbent powder, to be used in the same way and for the same purposes as iodoform. It is free from odor, and is alleged to be locally antiseptic.

BISMUTHI DITHIOSALICYLAS. (*Thioform.*) *Bismuth Dithiosalicylate.* $(S.C_6H_3(OH)COO)_2.BiO.BiO_2.Bi_2O_2 + 2H_2O$. This is a yellowish-gray, odorless, and tasteless powder, insoluble in water, alcohol, or ether. It has been used externally as a dusting powder in skin diseases and in surgery, and probably acts precisely as does dermatol. It has been employed upon the eye to a considerable extent and is not irritant. Internally it has been given in *diarrhœa* as an intestinal antiseptic in doses of five grains (0·32 Gm.) three or four times a day in capsules.

BISMUTHI GALLAS. *Bismuthum Gallicum Basicum. Dermatol.* $C_6H_2(OH)_3.COOBi(OH)_2$. F. T. Greene proposes the following formula. Normal bismuth nitrate, 1 oz. av.; glacial acetic acid, 2 fl. oz. or q. s.; gallic acid, 250 grains. Dissolve the normal bismuth nitrate in the glacial acetic acid; add a pint of water. If bismuth salts should precipitate, add more glacial acetic acid until clear. Filter off impurities. Dissolve the gallic acid in a pint of warm water; mix the solutions; allow the precipitate to subside; decant; wash by decantation with warm water until washings no longer show acid reaction. Dry at 100° C.; rub to powder. *Bismuth Subgallate* is a dry, fine powder, without odor, of a yellowish saffron color, which has been used by Heintz and Liebreich (*Gaz. Méd. de Paris*, June, 1891) as a substitute for iodoform. They have given internally as high as thirty-grain (1·94-Gm.) doses without the production of any disagreeable symptoms. Glaeser, after trial, condemns the remedy. (*Centralb. f. Gynaekolog.*, Oct. 1891.) On the other hand, dermatol has been strongly commended by Stierlin (*Corr.-Blatt f. Schweizer Aerzte*, April 1, 1892), by Doernberger (*T. G.*, May, 1892), by Werther, Rosenthal, Barber and König, and other clinicians, so that there would seem to be no doubt of its value in the local treatment of *eczemas*, *superficial ulcerations*, *wounds*, and other affections in which iodoform has been employed. It would appear, however, not to be a true substitute for iodoform, but a distinct astringent-sedative dressing, more like other bismuth preparations. The laboratory experiments of Bluhn and of Colasanti would seem to show that it is a feeble germicide, and to confirm the assertion of some surgeons that it cannot be relied upon in infected wounds, though useful in aseptic wounds and skin affections. According to Rosenthal, it is entirely free from toxic properties, but dermatol intoxication has occurred. (*Deutsch. Med. Wochensch.*, xxv., 1892.) In laboratory experiments, Colasanti found that the dried dermatol had no influence upon the growth of disease bacilli, but that in the wet state it was not inferior to iodoform. Dermatol has also been used with satisfactory results in *diarrhœas* as an astringent. It is no longer a patented medicine, and is much employed. Dose, from seven to thirty grains (0.5–2·9 Gm.).

BISMUTHI LACTAS. *Bismuth Lactate.* This salt may be made as follows. Take of bismuth subnitrate, *sixty-one parts;* ammonia water, *fifty parts;* lactic acid, *fifty-five parts;* distilled water, *a sufficient quantity.* Mix the bismuth subnitrate, in a flask, with the ammonia water previously diluted with *seventy-five parts* of distilled water. Let the mixture stand for one hour, pour off the supernatant liquid, and wash the residue thoroughly with distilled water. To the moist residue add the lactic acid, and evaporate the mixture to dryness on the water-bath. The product is a white powder, slowly soluble in water and insoluble in alcohol.

BISMUTHI OXYBROMIDUM. *Bismuth Oxybromide*, BiOBr, is an impalpable yellow powder, used internally in gastric affections.

BISMUTHI OXYIODIDUM. Bi.OI. This compound, sometimes termed *Bismuthi Subiodidum*, may be made by F. X. Moerk's process, as follows. Take of iodine, 4·6 Gm.; bismuth subnitrate, 10 Gm.; nitric acid, sp. gr. 1·42, 10 C.c.; solution of soda, U. S. P., 150 C.c.; water, a sufficient quantity. The iodine is covered with 50 C.c. of water, and converted into hydriodic acid by passing hydrogen sulphide through the mixture, boiling to remove excess of hydrogen sulphide, and filtering. The subnitrate is dissolved in the nitric acid, diluted with 10 C.c. of water, and then enough water added to produce a slight permanent opalescence; this mixture is then slowly poured into the solution of soda, taking the precaution to stir constantly. The precipitate is washed by decantation until the washings cease to turn red litmus-paper blue; 50 C.c. of water are added to it, and the hydriodic acid gradually poured in, until after stirring and allowing to settle the supernatant liquid has a yellow color. The oxyiodide is washed by decantation, removed to a filter, allowed to drain, and, finally, dried at a temperature not exceeding 100° C. The oxyiodide has a light yellowish-red color, and contains no water of crystallization. (*A. J. P.*, 1887, 273.) In 1877 the bismuth oxyiodide was recommended as a local antiseptic and substitute for iodoform, by A. Sidney Reynolds, and in the *Medical News*, Oct. 1886, he reaffirmed its value. It has been used to a considerable extent with success in the Philadelphia Hospital, but its high price interferes with its general adoption. It has also been given internally in *gastric ulcer* and other gastric affections for which bismuth is usually employed. The dose is from five to ten grains (0·32–0·64 Gm.).

BISMUTHI SUBSALICYLAS. $Bi(C_7H_5O_3)_3.Bi_2O_3$. Basic *Bismuth Subsalicylate* is a white, amorphous, tasteless and odorless powder, containing 63 per cent. of bismuth. It is probably to some extent broken up in the alimentary canal, as Schmey has seen a rash follow its use, but as much as one hundred and fifty grammes of it have been given without disagreeable effects. It has been used in *diarrhœa*, typhoid fever, etc., as an intestinal antiseptic in doses of from five to fifteen grains (0·32–0·97 Gm.) frequently repeated.

BISMUTHI SULPHIS. $Bi_2(SO_3)_3$. *Bismuth Sulphite* is made by reacting on normal bismuth ni-

trate with sodium sulphite. It is an antiseptic and antiferment with anthelmintic properties.

BISMUTHI TANNAS. *Bismuth Tannate* has been used as astringent in *diarrhœas* in doses of from ten to thirty grains (0·65–1·98 Gm.).

BISMUTHI VALERIANAS. *Bismuth Valerianate. Valerianas Bismuthicus. Valérianate de Bismuth*, Fr. *Wismuthvalerianat*, G. $Bi(C_5H_9O_2)_3$. This salt is formed by double decomposition between solutions of bismuth ternitrate and sodium valerianate. Bismuth valerianate precipitates as a white powder, which is washed with water, and dried with a gentle heat. It has been recommended by Righini in *neuralgia*, and in *gastrodynia*. The dose is from half a grain to two grains (0·032–0·13 Gm.), repeated several times a day, and given in the form of pill.

BISMUTHUM CHRYSOPHANICUM. *Dermol.* $Bi(C_{15}H_9O_4)_3.Bi_2O_3$. This is a yellow, amorphous, insoluble powder, which has been used in the treatment of various diseases of the skin.

BISMUTHUM LORETINICUM. *Loretin Bismuth. Bismuth Iodo-oxyquinoline-sulphonate.* This compound has been used in the dose of 0·5 Gm. every four hours in the treatment of tubercular and other obstinate diarrhœas, and as a local application in powder form to *epithelioma*, *syphilitic* and other forms of infected *ulcers*. The 10 per cent. lanolin ointment has been recommended in *eczema* and *psoriasis*.

BISMUTHUM PHOSPHORICUM SOLUBILE. *Soluble Bismuth Phosphate*, which is prepared by the melting together of bismuth, soda, and phosphoric acid, is a powder easily soluble in water, precipitated by alkalies, acids, or heat, and undergoing spontaneous decomposition when in concentrated solution. It contains 20 per cent. of bismuth, and has been used as an intestinal antiseptic in *choleraic* and other acute *diarrhœas* in the dose of from three to eight grains (0·2–0·5 Gm.) three times a day.

BISMUTHUM PYROGALLICUM. *Helcosol.* $C_6H_3(OH)_2OBiO$. *Bismuth Pyrogallate* is a yellowish-green, amorphous powder, insoluble in water and alcohol, soluble in acid and alkaline solutions and in the gastro-intestinal juices. According to von Heyden, it contains about 60 per cent. of bismuth. In very large doses it is said to be non-poisonous, and to be a valuable intestinal antiseptic; if, however, pyrogallic acid should be liberated in the alimentary canal, it might produce disagreeable effects, and the remedy seems to us very ineligible.

BISMUTHUM SODIUM PHOSPHATE SALICYLATE. *Bismuthol. Bismutal.* This substance, which is probably a mere mixture of the bismuth phosphate and the sodium salicylate, is a white, crystalline, odorless powder, soluble in water, which has been commended by Radlauer as an antiseptic in the treatment of wounds and inflammations of the mucous membrane. It may be used with talc (from 1 to 2 to 1 to 5) as a powder, or in a 10 to 20 per cent. salve with vaseline, or as a 1 to 4 per cent. aqueous solution, in the treatment of *infected wounds*, *syphilitic* and other *ulcers*, and as an injection in *gonorrhœa* in chronic *sinuses*, etc. It has been especially recommended for excessive *sweating of the feet.*

BISTORT. *Snakeweed. Bistorte, Couleuvrine*, Fr. *Weissenknöterich Natterwurz*, G. This is the root of *Polygonum Bistorta*, L. (nat. ord. Polygonaceæ), a perennial herbaceous plant, growing in Europe and the north of Asia. The root is cylindrical, somewhat flattened, about as thick as the little finger, marked with annular or transverse wrinkles, furnished with numerous fibres, and folded or bent upon itself, so as to give it the tortuous appearance from which its name was derived. When dried, it is solid, brittle, of a deep brown color externally, reddish within, inodorless, and of a rough, astringent taste. It contains much tannin, some gallic acid and gum, and a large proportion of starch. H. K. Bowman found 21 per cent. of tannin in bistort root. (*A. J. P.*, 1869, 193.) Its medical properties are like those of kino, but it is less efficient, and in this country is seldom used. It may be employed in powder, decoction, or extract. The dose of the powder is twenty or thirty grains (1·29 or 1·94 Gm.).

Besides the bistort, some other plants belonging to the genus Polygonum have been used as medicines. Among these are *P. aviculare*, L., or *knot grass*, a mild astringent, formerly employed as a vulnerary and styptic; *P. persicaria*, L. (*Persicaria mitis*, Gilib.), of a feebly astringent saline taste, and at one time considered antiseptic; and *P. hydropiper*, L., or water-pepper (*Persicaria hydropiper*, Opiz), the leaves of which have a burning and biting taste, inflame the skin when rubbed upon it, and are esteemed diuretic, and have been used with asserted success in *amenorrhœa* and other *uterine disorders.* Its irritant and also medicinal properties are due to an acid, *polygonic acid*, discovered by C. J. Rademaker. (*A. J. P.*, xliii. 490.) The *water-pepper* or *smart-weed* of this country,—*P. punctatum*, Ell., *P. hydropiperoides*, Mich.,—which grows abundantly in moist places, possesses properties similar to those of the European water-pepper, and is occasionally used as a detergent in chronic *ulcers*, and internally in *gravel.* B. Woodward finds that the dried plant contains 18 per cent. of tannin, and uses a saturated tincture with great advantage in *diarrhœa* and *dysentery*, in doses of from twenty to sixty minims (1·23–3·69 C.c.). Aughey finds that *P. amphibium* is readily cultivated, with a yield of from three to six tons to the acre, that the roots contain 21·75 per cent., the stems 17·1 per cent. of tannic acid, and urges the growth of it for tanning purposes. (*N. R.*, 1876, 75.) *P. fagopyrum* is common *buckwheat.* The leaves of this plant have been found by Ed. Schunck to contain a crystallizable coloring principle, identical with the *rutin* or *rutic acid* previously discovered by Weiss in the leaves of the common rue, and probably, with the *ilixanthin* of Moldenhaus, existing in the leaves of *Ilex aquifolium* or common holly. Buckwheat leaves yielded to Schunck somewhat more than one part of rutin in a thousand. (*Chem. Gaz.*, No. 399, 201.) From *P. cuspidatum* has been separated a glucoside, *Polygonin*, and also *Emodin.* (*P. J. Tr.*, Feb. 1896.)

Various species of the genus Polygonum are used for the production of dye-stuffs; thus, indigo is obtained largely in China, Japan, and in some parts of Russia, from the leaves of the *P. tinctorium*, and is said also to be yielded by those of *P. aviculare* and *P. barbatum;* whilst in India, China, and Japan the roots of the *P. cuspidatum* are employed for making a yellow dye. (*Journ. Chem. Soc.*, Dec. 1895.)

BLACK WAX. This appears to be a product of animal life which has found its way to England from India and the Pacific Islands. (*P. J. Tr.*, 2d ser., x. 11, 219.)

BLENNOSTASINE. W. F. Chappell (*N. Y. Med. Journ.*, lxiv., 1896) asserts that this derivative of a cinchona bark alkaloid is a powerful sedative to the brain and spinal cord, and that in doses of from one to four grains every hour it is a valuable remedy in nasal and laryngeal hyperæsthesia.

BLOOD OF BULLOCKS. As long ago as 1852 Samuel Jackson, of Philadelphia, employed as a tonic the blood of bullocks carefully dried *in vacuo*, giving from five to ten grains of it as a dose. Recently it has been used considerably in Europe, and even drinking fresh bullock's blood was at one time in fashion. Under the name of *Sanguis Bovinus Exsiccatus*, F. E. Stewart has introduced defibrinated dried bullock's blood, claiming for it that, by the simple addition of water, bullock's blood can be reproduced minus a small quantity of fibrin. There is no reason for believing that dried blood is more valuable than the more usual ferruginous tonics, if indeed it be of equal value.

BLUMEA LACERA. D.C. (Nat. ord. Compositæ.) From this plant, which is used in India as an insect powder, Dymock has obtained a light yellow volatile oil. It has a sp. gr. of 0·9144 at 80° F., and an extraordinary rotating power, 1 Mm. turning the ray 66° to the left.

BOCCONIA. It is probable that various species of this papaveraceous genus have active medical properties. *B. arborea*, Watson, of Mexico, has been found by Elliott to contain two alkaloids, one of which is probably *sanguinarine;* and the leaves of other species are used in South America as abortifacients, purgatives, etc. (See Rusby, *Bull. Pharm.*, 1891.)

BOLDO. *Boldus.* This plant is an evergreen shrub, frequenting the meadows of the Andes in Chili, where its yellowish-green fruit is eaten, its bark used in tanning, and its wood in charcoal-making. It is the *Peumus Boldus* of Molina (1782); *Peumus fragrans*, Pers.; *Boldea fragrans*, C. Gay, also Juss.; *Ruizia fragrans*, Pav. (Nat. ord. Monimiaceæ.) The leaves, which contain a large amount of an aromatic volatile oil in especial cells, are the parts used in medicine. They are entire, reddish brown when dry, coriaceous, with a prominent midrib and very numerous small glands upon their surface. A peculiar alkaloid, *Boldine*, has been found in them by MM. Bourgoin and Verne (*Journ. de Pharm.*, 4e sér., xvi. 191), and a glucoside, *Boldoglucin*, $C_{30}H_{52}O_8$, by P. Chapoteaut. (*Compt.-Rend.*, xcviii. 1052.) According to Sigismond Pascaletti (*Terapia Moderna*, 1891), *boldine* when injected hypodermically paralyzes both the motor and sensory nerves, and also attacks the muscle fibres. As a local anæsthetic he believes it to be superior to caffeine but inferior to cocaine. When given internally in toxic dose it produces great excitement, with exaggeration of the reflexes and of the respiratory movements, increased diuresis, cramps, disorder of coördination, convulsions, and finally death from centric respiratory paralysis; the heart continuing to beat long after the arrest of respiration, and finally stopping in diastole. Boldoglucin is said to act on the lower animals as a narcotic, and has been given by Réne Juranviller, with asserted success, as a hypnotic and calmative remedy in *insanity*. The dose is from twenty to sixty grains enclosed in capsules. (*Paris Thèse*, 1885, 346.) Fifteen minims of the oil cause in man some warmth in the epigastrium; half a drachm, much gastric irritation, with pain and vomiting, and passage of urine smelling strongly of the oil. Dujardin-Beaumetz finds the oil useful in *genito-urinary inflammations* in doses of five drops (*Bull. Gén. de Thérap.*, Mars, 1875), in diseases of which character the drug has long been employed in South America. (*Ibid.*, lxxxvi. 165.) In France boldo has been employed as a tonic in *chronic hepatic torpor* and in *hepatitis*. (*Etude sur le Boldo*, C. Verne, Paris, 1883.) Eight minims (0·5 C.c.) of a tincture (1 to 5) or four minims (0·24 C.c.) of a fluid extract may be considered as the commencing dose, increased *pro re nata*. Large doses are apt to vomit and purge.

According to A. T. De Rochebrune (*Toxicol. Africaine*, i., 1897), the tree *Monimia rotundifolia*, of Australia, contains an abundant volatile oil, an alkaloid, and a glucoside, which are very similar to, if they be not identical with, those obtained from the *Boldo*, for which they may be substituted in therapeutics

BOLE ARMENIAN. *Bolus Armena. Bolus Rubra. Argilla Ferruginea.* The term *bolus* or *bole* was formerly applied to various forms of argillaceous earth, differing in color or in place of origin. Such were the *Armenian*, *Lemnian*, and *French boles*, and the *red* and *white boles*. Some of these substances were so highly valued as to be formed into small masses and impressed with a seal, and hence received the name of *terræ sigillatæ*. They were all similar in effect, though the small proportion of oxide of iron contained in the colored boles may have given them greater activity. The only one at present kept in the shops is that called *bole Armenian*, from its resemblance to the substance originally brought from Armenia. It is prepared, by trituration and elutriation, from certain native earths existing in different parts of Europe. It is in pieces of various sizes, reddish, soft, and unctuous, adhesive to the tongue, and capable of forming a paste with water. It consists chiefly of a hydrated aluminum silicate with ferric hydrate. The boles were formerly employed as absorbents and astringents in *acidity of the stomach* and in *relaxed bowels*. Bole Armenian is used chiefly as a coloring ingredient in tooth-powders.

BONDUC SEEDS. These are seeds derived from several species of the genus *Guilandina*, now *Cæsalpinia* (nat. ord. Leguminosæ), which are used in India as febrifuges, tonics, and antiperiodics. Messrs. Heckel and Schlagdenhauffen have discovered in them a bitter principle (*Compt.-Rend.*, 103, 89), probably identical with that previously isolated by Professor Flückiger. (*Pharmacographia*, 2d ed., 212.)

BORAGO OFFICINALIS. L. *Borage. Bourrache*, Fr. *Borasch, Boretsch*, G. (Nat. ord. Boraginaceæ.) This European annual abounds in mucilage, and the stem and leaves contain potassium nitrate with other salts. To these constituents the plant owes all its virtues. It is much used in France. An infusion of the leaves and flowers, sweetened with honey or syrup, is employed as a demulcent, refrigerant, and gently diaphoretic drink in *catarrhal affections*, *rheumatism*, *diseases of the skin*, etc. The expressed juice of the stem and leaves is also given in the dose of from two to four ounces. The flowers are sometimes applied externally as an emollient.

BORAL. *Aluminum boro-tartrate* is soluble in water, and is in fine powder. *Aluminum boro-tan-*

nate (*cutol*) contains 47 per cent. of tannin. Both salts are used as astringents by dermatologists.

BOROGLYCERIDE. *Boroglycerinum. Glycerylborate.* This substance has been largely employed as a convenient form of obtaining boric acid in a soluble condition. It is made by heating boric acid and glycerin together so as to effect a combination without discoloring the product by overheating. (See *Boroglycerinum*, National Formulary, p. 1488; also *Glyceritum Boroglycerini*, PART I.) Mr. James Kennedy (*Nat. Druggist*, 1887, 46) maintains that it is a chemical compound, and not a mere mechanical mixture, as has been supposed; he gives it the formula $C_3H_5BO_3$, and expresses the reaction in its formation thus: $C_3H_5(OH)_3 + H_3BO_3 = C_3H_4BO_3 + 3H_2O$. The metallic boroglycerides, such as sodium and calcium boroglyceride, are not explained, however, in this case. Aqueous solutions of boroglyceride are used for preserving milk, meat, fruit-juices, etc. Under the name of *glacialin* a substance has been largely sold in England which is simply boroglyceride.

BOROL. This is a compound in which either Potassium (K) or Sodium (Na) joins with Boron (B) to replace the two atoms of Hydrogen (H) in Sulphuric Acid (H_2SO_4), giving either of the two formulæ, $BKSO_4$ or $BNaSO_4$. It occurs in irregular, colorless, odorless, vitreous fragments, soluble in five times its weight of water. According to H. Jäger, it is three times as powerful as carbolic acid as an antiseptic, the 2 per cent. solution rapidly destroying most pathogenetic germs. It has been used internally in various germ diseases, and externally in *diphtheria*, *gonorrhœa*, *ozæna*, *psoriasis*, and other surgical affections. Dose, from thirty to fifty drops of a 20 per cent. solution, well diluted. Locally a 1 to 2 per cent. solution has been used. (*Therap. Wochensch.*, iv.)

BORO-PHENOL is a combination of borax and carbolic acid. It has an agreeable odor, is completely soluble in water, and can be used for all the purposes for which carbolic acid disinfectants are used.

BORO-SALICYLIC ACID has been introduced by Cesaris and Carcano as an antiseptic; the solution contains 4 per cent. each of boric and salicylic acids.

BORSALICYL is made by Bernegau by triturating thirty-two parts of sodium salicylate with twenty-five parts of finely powdered boric acid with a little water; the hardened mass is dried and powdered. It is used as an antiseptic. (*Apoth. Zeit.*, 1894, 876.)

BOWDICHIA MAJOR. Mart. (Now *B. virgiloides*, H. B. K.) (Nat. ord. Leguminosæ.) Under the name of *Sucupira*, the hard, yellow, very bitter bark yielded by this tree is employed in Brazil in *fevers* and *rheumatism*. Mr. Petit has found in it a mydriatic alkaloid. (*P. J. Tr.*, June, 1885.)

BRAGANTIA WALLICHII. The roots of this shrub of India contain an alkaloid allied to *aristolochine*, a soft resin, a resinous acid, and a substance related to dulcite. (*P. J. Tr.*, 1894, 231.)

BRASSICA. In China the oil of *Brassica sinensis*, or *petsai*, is used for lighting, and is said also to be purgative, and useful in *skin diseases*, whilst the Japanese employ the yellow oil of *B. campestris*, under the name of *aburana*, for culinary and lighting purposes. (*A. J. P.*, June, 1885.)

BRAZIL NUTS. *Cream Nuts. Pará Nuts. Châtaigne du Brésil*, Fr. *Paranuss*, G. These are edible nuts imported from Brazil, and sometimes employed in making cream syrups for giving flavor to carbonic acid water. In Brazil an expressed oil is obtained from them, which is said to be used for burning, making ointments, and adulterating copaiba. Dr. Edward Donnelly, of Philadelphia, states (*Proceedings Am. Pharm. Assoc.*, 1858, 327) that the nuts are the product of the *Bertholletia excelsa* (Humboldt and Bonpland), a large and beautiful tree of the nat. ord. Myrtaceæ, growing over extensive regions in South America. Corenwinder has found in the kernel of the nut 65·60 per cent. of oil, and 15·31 per cent. of nitrogenous matter. (*P. J. Tr*, Aug. 1873.)

BRAZIL WOOD. A red dye-wood, the product of different species of Cæsalpinia, growing in the West Indies and South America. Two varieties are known in commerce,—1, the proper Brazil wood, said to be derived from *Cæsalpinia echinata*, Lam., and sometimes called *Pernambuco* or *Fernambuco wood*, from the province of Brazil, where it is collected; 2, the *brasiletto*, produced by *C. brasiliensis*, L., and *C. crista*, L., which grow in Jamaica and other parts of the West Indies. The former is the most highly valued. The *sappan* or *samfen wood* may be referred to the same head, being obtained from the *Cæsalpinia sappan*, and possessing properties analogous to those of the brasiletto. The *Nicaragua* or *peach wood* is also analogous to the brasiletto, and is said by Bancroft to be derived from a species of Cæsalpinia. It is produced in the East Indies. Brazil wood is nearly inodorous, has a slightly sweetish taste, stains the saliva red, and imparts its coloring matter to water. It was formerly used in medicine; but has been abandoned as inert. In pharmacy it serves to color tinctures, etc.; but its chief use is in dyeing. A red lake is prepared from it, and it is an ingredient in a red ink. Its dyeing properties are owing to a crystallizable coloring principle, named *brazilin* or *brasilin*, $C_{16}H_{14}O_5$. This, as usually obtained, is of a sulphur-yellow color, which it preserves in the dark, but soon loses in the sunlight, to which it is remarkably sensitive, changing to a reddish hue after a few minutes' exposure, and undergoing a similar alteration in diffused daylight, though more slowly. The principle should, therefore, be kept in perfectly opaque vessels. It is now stated that when absolutely pure it is colorless, and becomes red on exposure to the air. The change is due to the formation of *brasilein*, $C_{16}H_{12}O_5$, which can be prepared from the brasilin by a variety of methods, such as oxidation by nitrous acid, by alcoholic iodine solution, etc. Brasilin is sparingly soluble in water, yielding a sweet and almost colorless solution which is not changed by acids, but is deeply reddened by alkalies. In alcohol and ether it is somewhat more soluble than in water, giving a light yellow solution. The colorless aqueous solution soon becomes reddish in the air, afterwards yellowish red, and acquires the curious property of phosphorescing in a golden-yellow light. (C. F. Schönbein, *Neues Repertor.*, 1868, Bd. xvii., Theil vii., 390; *Journ. de Pharm.*, 4e sér., xix. 88.)

BROMAL. C_2HBr_3O. This substance resembles chloral in its chemical properties, like it existing as an oily colorless liquid, or, when united with water or alcohol, as a crystalline hydrate or alcoholate. It boils at about 172° C. (342° F.), and distils without decomposition. It is prepared by adding, little by little, from 3 to 4 parts of bromine to re-

frigerated alcohol. After fifteen hours of contact the mixture is distilled. The bromine and other very volatile products come over first, and afterwards, at a temperature of from 160° C. (320° F.) to 180° C. (356° F.), the bromal, with an oily substance insoluble in water. Water being added, *bromal hydrate* (C_2HBr_3O,H_2O) is formed in rhombic scales fusing at 53·5° C. (128° F.). By the action of an alkali, bromoform is produced from the bromal hydrate. According to S. Steinauer (*Virchow's Archiv*, May 19, 1870), in frogs and mammals bromal produces at first great restlessness, followed by sleep of moderate intensity, accompanied by an almost complete analgesia. Dyspnœa was usually very marked, and death sometimes occurred in convulsions. The cardiac ventricles after death were relaxed or tetanized, according as the dose had been large or small. Dr. Steinauer believes that the succession of symptoms is due to the first action being that of the bromal, and the subsequent, that of bromoform and nascent bromides generated in the blood from the bromal hydrate. Dr. Steinauer administered the drug to several patients, in doses of three grains (0·194 Gm.) at bedtime, with the effect of relieving pain or producing sleep. In *epilepsy* it seemed to avert the paroxysms.

BROMALIN. *Bromethylformin. Hexamethylenetetramine-bromethylate.* $(CH_2)_6N_4.C_2H_5Br$, is formed by the action of ethyl bromide upon hexamethylenetetramine. It occurs in colorless scales or white powder, melting at 200° C. with decomposition; nearly tasteless, readily soluble in water. It has been used, especially by Bardet, as a sedative and substitute for the bromides. The dose is from thirty to sixty grains (1·9–3·88 Gm.).

BROMAMIDE. *Tribromaniline Hydrobromate.* $C_6H_2Br_3NH_2HBr$. This substance, which is said to contain 75 per cent. of bromine, and to be very stable, occurs in odorless, tasteless, colorless, needle-shaped crystals, insoluble in water, but soluble in sixteen parts of boiling alcohol, in chloroform, ether, and the fixed oils. It melts at 243° F., and volatilizes at 310° F. without change. It has been proposed by A. Caillé (*New York Med. Journ.*, 1892) as an antipyretic, antirheumatic, and analgesic. Dose, from ten to fifteen grains (0·65–0·97 Gm.).

BROMINE CHLORIDE. *Brominii Chloridum.* BrCl. This chloride is prepared by passing chlorine gas through bromine, and condensing the vapors which form by a freezing mixture. It is a reddish-yellow, very mobile and volatile liquid, emitting dark yellow fumes, which have a very powerful odor, and cause a flow of tears. Its taste is hot and unpleasant. Bromine chloride is used by Landolfi, of Naples, internally, in the treatment of *cancer* and as an ingredient in his caustic.

BROMOFORM. *Tri-brom-methane. Formyl bromide* ($CHBr_3$) is produced by the action of bromine upon alcohol in the presence of an alkali. In practice, milk of lime is saturated with bromine, alcohol added, and the mixture distilled. It is also prepared by the action of sodium hypobromite upon acetone by a reaction analogous to that used in the manufacture of chloroform. It is a colorless liquid, boiling at 151° C. and solidifying at 2·5° C. Sp. gr. 2·83 at 0° C.

In 1849 Nunneley and Schuchard called attention to bromoform as a possible agreeable anæsthetic, and in 1869 Rabuteau (*Gaz. Hebdom. de Méd.*) brought the drug forward as a new anæsthetic. Given to the lower animals by inhalation or hypodermic injection, bromoform produces rapid narcosis, in which, according to the researches of Von Horoch (*Wien. Medizin. Jahrb.*, 1883), the breathing is not distinctly lessened, and the pulse remains full, regular, and strong, although the blood-pressure is distinctly reduced; the heart itself is said not to suffer from the influence of the drug, and the peripheral vagi are not affected; further, as powerful irritation of a sensory nerve has no influence upon the blood-pressure, it is probable that the fall is the result of vaso-motor paralysis, which is confirmed by the rapid sinking of the temperature. The excitability of the cerebral psycho-motor centres and the general reflexes are entirely destroyed. Von Horoch has used the bromoform as an anæsthetic in several cases in man. The most marked symptom was excessive cyanosis of the face. The urine passed after recovery contained bromine. Binz has also found bromine in the urine of animals poisoned with bromoform. Elimination of the drug would seem, however, to take place very slowly, as unless the animal survived several days no bromine could be detected. (*Deutsch. Med. Zeitung*, 1891.) A number of cases of poisoning by bromoform have been recorded. (*L'Union Méd.*, Sept. 1891.) The symptoms have been pallor, titubation, dilatation of the pupil, coma, heart failure, collapse. Bromoform has been strongly recommended in *whooping-cough* by Stepp and other clinicians, and is said to act as a local anæsthetic upon the pharyngo-laryngeal mucous membranes. Stepp's dose, administered in a teaspoonful of water, is, for children three or four weeks old, one drop three or four times daily; in older, nursing children, three drops, according to the intensity of the attack; in children from two to four years of age, four to five drops three or four times daily; up to seven years of age, six to seven drops three or four times daily. Three drops, however, are reported to have produced very serious symptoms in a child four years old, and two drops in one fifteen months old. When bromoform is given internally it should be administered in capsules or dropped on sugar, as it is very prone to precipitate from mixtures.

BROMOL. *Tribromophenol. Tribromphenol.* $C_6H_2Br_3OH$. Bromol is obtained as a white flocculent and gradually crystallizing sediment when bromine water is added to an aqueous solution of carbolic acid. Pure tribromophenol occurs as a white crystalline substance which melts at a temperature of 203° F., and is nearly insoluble in water, but readily so in alcohol, ether, chloroform, glycerin, and in fatty and ethereal oils; the odor is disagreeable, like that of bromine, but more penetrating; the taste is sweet and astringent. According to Grimm and Rademacher, tribromophenol is a powerful antiseptic and disinfectant, which, when in concentrated form, acts as a caustic, and is especially valuable in the treatment of *tuberculous ulcers* and *gangrene*. Grimm considered the remedy too caustic to be used upon the mucous membranes of the upper air-passages, but Rademacher has used it in the solution of olive oil (one to thirty) with asserted excellent results in *diphtheria*. It is said to be very slowly acted upon by the intestinal juices, and has been used as an intestinal disinfectant in doses of from three to seven and one-half grains (0·19–0·48 Gm.) a day. That it is absorbed in some form is shown by the fact of its excretion in the urine in the form of *tribromophenol-sulphonic acid*.

BROMOPYRIN. *Monobromantipyrin.* $C_{11}H_{11}BrN_2O$. This occurs in white crystalline needles, almost insoluble in cold water, scarcely soluble in hot water, easily soluble in alcohol and chloroform. Its melting point is 114° C. Its influence upon the system seems not to have been investigated. A mixture of antipyrin, caffeine, and sodium bromide has been sold as bromopyrin.

BURRA GOOKEROO. Under this name, in India, the fruit and sometimes the whole plant of the *Tribulus lanuginosus* (nat. ord. Zygophylleæ) is used as a diuretic and aphrodisiac. The carpels have been commended in London as a remedy in *nocturnal emissions;* dose of fluid extract, from twenty minims to one drachm (1·23–3·7 C.c.).

BUTEA FRONDOSA. This is a plant which grows in Western India. The leaves are said to be astringent and stimulating to the sexual organs, and the seeds anthelmintic. The resin has reached Europe in small pieces of a deep red color, usually opaque, and of a pure astringent taste. N. Weber (*Pharm. Zeitschrift für Russland*, 1886) failed to find an alkaloid in the seeds.

BUXUS SEMPERVIRENS. L. *Box.* (Nat. ord. Euphorbiaceæ.) This evergreen shrub is too well known to require description. Though much cultivated in this country as an ornamental plant, it is a native of Europe and Western Asia. The wood is considered diaphoretic in its native countries, and is used in decoction in *rheumatism*, *secondary syphilis*, etc. The leaves, which have a peculiar odor and a bitter and disagreeable taste, are said to be purgative in the dose of a drachm. A volatile oil distilled from the wood has been given in *epilepsy*. A tincture formerly enjoyed some reputation as an antiperiodic. (Mérat and De Lens.) In 1860 it was determined by Walz that *buxine*, an alkaloid which had been discovered in the leaves of this tree, is identical with the bebeerine of the bebeeru or nectandra bark. (See *Nectandra;* also *P. J. Tr.*, Oct. 1869, 194.) Pavia obtained a second alkaloid from *Buxus sempervirens*, which was investigated by Pavesi and Rotondi. (*Jahresberichte*, 1874, 903.) They name it *parabuxine*, and ascribe to it the formula $C_{24}H_{43}N_2O$. Barbaglia (*A. J. P.*, 1885, 145) describes still another alkaloid, *parabuxinidine*. It crystallizes in thin, colorless prisms, is insoluble in water, soluble in ether, freely soluble in alcohol, and colors turmeric paper deep red.

BYTTERA FEBRIFUGA. *Bitter Ash.* The name *Byttera febrifuga* was given by M. Bélanger to a tree growing in Martinique, in the West Indies, which is now believed to be the *Quassia excelsa* of Linn. (See 16th ed. *U. S. D.*)

CABBAGE-TREE BARK. *Ecorce de Geoffrée*, Fr. *Kohlbaumrinde, Wurmrinde*, G. The bark of *Andira inermis*, H. B. K. (*Geoffræa inermis*, Sw.) This is a leguminous tree, with a stem rising to a considerable height, branched towards the top, and covered with a smooth gray bark. The leaves are pinnate, consisting of six or seven pairs of ovate-lanceolate, pointed, veined, smooth, petiolate leaflets, with an odd one at the end. The flowers are rose-colored, and in terminal panicles, with very short pedicels. The tree is a native of Jamaica, and other West India islands. The bark, which is the part used, is in long pieces, thick, fibrous, externally of a a brownish-ash color, scaly, and covered with lichens, internally yellowish, of a resinous fracture, a disagreeable smell, and a sweetish, mucilaginous bitterish taste. Its powder resembles that of jalap. Huttenschmidt obtained from it a crystallizable, very bitter substance, having the composition and neutralizing properties of the vegetable alkaloids, and named it *jamaicine*. Two grains of it produced violent purging in pigeons.

Theodore Peckolt says of the wood of the tree, which he calls *Andira anthelmintica* (Benth.), that the workmen engaged in sawing it are apt to be affected with inflammation of the eyes, constriction of the throat, excessive thirst, a bitter, burning taste, a troublesome itching over the body, and sometimes eruptions on the skin. By treating a concentrated decoction of the wood with lime hydrate, then filtering after forty eight hours, evaporating to the consistence of syrup, and exhausting the residue with alcohol, Peckolt obtained a yellowish-brown coloring matter which he called *andirin*. (This name has also been given to a glucoside said to have been found in *Andira inermis*. See *A. J. P.*, 1885, 558.) Peckolt also obtained a peculiar resin by treating the wood with alcohol, filtering, distilling off most of the alcohol, and then precipitating by water. The resin is inodorous, of a bitter, acrid taste, soluble in alcohol, and but partially soluble in ether. This resin, and especially the portion soluble in ether, gives its irritating properties to the sawdust. (*Chem. Centralbl.*, Nov. 17, 1858.)

Cabbage-tree bark is cathartic, and, in large doses, apt to occasion vomiting, fever, and delirium. It is said that these effects are more liable to result if cold water be drunk during its operation, and may be relieved by the use of warm water, castor oil, or a vegetable acid. In the West Indies it is esteemed a powerful vermifuge, and is much employed for expelling *lumbrici;* but it is dangerous if incautiously administered, and instances of death from its use have occurred. It is almost unknown in this country. The usual form of administration is that of decoction, though the medicine is also given in powder, syrup, and extract. The dose of the powder is from twenty grains (1·29–1·95 Gm.) to half a drachm, of the extract three grains, of the decoction two fluidounces (59·1 C.c.).

On the continent of Europe the bark of *Andira retusa*, H. B. K. (*Geoffræa surinamensis*, Bondt.), which grows in Surinam, has also been used. It is considered more powerfully vermifuge and less liable to produce injurious effects. It has a grayish epidermis, beneath which it is reddish brown, laminated, compact, and very tenacious, and, when cut transversely, exhibits a shining and variegated surface. In the dried state it is inodorous, but has an austere bitter taste. The powder is of a pale cinnamon color.

CACTUS BONPLANDII. H. B. K. (Now *Opuntia Tuna.* Mill.) (Nat. ord. Cactaceæ.) This plant is asserted to have the properties of *C. grandiflorus.* (See *Newer Mat. Med.*)

CACTUS GRANDIFLORUS. L. (Now *Cereus grandiflorus.* Mill.) *Night-blooming Cereus. Cierge à grandes Fleurs*, Fr. *Königin der Nacht*, G. (Nat. ord. Cactaceæ.) This plant, a native of tropical America, has a branching, fleshy, green stem, with five or six angles; beset with clusters, with five or six short radiating spines. The numerous imbricated calyx lobes are linear, acute, brownish, the inner ones yellow. The flowers, which open in the night, are very fragrant, and produce an orange-colored, internally white berry,

the size of an egg. F. W. Sultan finds in it *cactine*, a supposed alkaloid. (*A. J. P.*, 1891, 424.)

The cactus grandiflorus has long had a reputation among the natives of those countries in which it grows as a cure for *dropsy*, but appears to have been first brought into notice by Dr. Rubini, of Naples, as a cardiac remedy. Dr. O. M. Myers (*N. Y. Med. Journ.*, June, 1891) alleges that in therapeutic dose it,—1. Increases the musculo-motor energy of the heart,—probably through its influence upon the intra-cardiac motor and accelerator ganglia, in consequence of which the cardiac impulses become regular and much stronger. 2. Elevates the arterial tension, increasing correspondingly the height and force of the pulse-wave: this is produced by,—*a*, increased cardiac action; *b*, stimulation of the vaso-motor centre at the base of the brain. 3. Stimulates the spinal motor centres, increasing the activity of the centres and the general nerve-tone. The results of Myers have been partially confirmed by MM. Boy-Teissier and Boinet. (*Marseille Méd.*, 1891.) According to Dr. Myers, cactine is not irritating, but the crude drug is said to be used as a counter-irritant, and to produce pustulation.

Cactus has been favorably reported upon as a cardiac stimulant by a number of practitioners as a partial substitute for digitalis. It is affirmed to be especially valuable in the functional disorders of the heart connected with *dyspepsia*, *neurasthenia*, *anæmia*, *Graves's disease*, *tobacco toxæmia*, *sexual exhaustion*, and allied affections. It has also been used with asserted good results as a stimulant to the heart in low *fevers*, and even in *angina pectoris*. Dr. P. W. Williams, of London, however, states that whilst of great value in *pseudo-angina*, it has little power over the true disease. It appears not to prolong the diastole, as does digitalis, and on this account has been especially recommended in complicated aortic regurgitation. In our own therapeutic trials cactus has failed to produce any results; and certainly the existence of the alleged alkaloid *cactine* is not assured. Sharp could only obtain from the drug resins which were not physiologically active, and concludes that the drug is inert. (*Practitioner*, Sept. 1894.) According to Williams, the maximum dose of the tincture, four ounces of the fresh stems to a pint of strong alcohol, is thirty minims (1·85 C.c.) every four hours, and of the fluid extract twelve minims (0·74 C.c.). The dose of cactine seems not to have been determined.

CACUR. This is a small gourd which while still unripe is used by the Caffirs as an emetic, and which, according to Professor Oliver, is yielded by the *Cucumis myriocarpus*, Nand. (Nat. ord. Cucurbitaceæ.) Dr. G. A. Atkinson (*A. J. P.*, 1887) obtained from it a neutral resinous body, *myriocarpin*, and found that twenty grains (1·29 Gm.) of the fresh pulp produced in man nausea and slight purgation. (*Edin. Med. Journ.*, July, 1886.)

CADMIUM. *Cadmium. Cadmium*, Fr., G. *Kadmium*, G. This metal is associated with zinc in its ores, occurring principally as *greenockite* (CdS), a yellowish incrustation upon zinc *blende* (ZnS), and, being more volatile than that metal, comes over with the first portions of the zinc in the process for obtaining it. (See *Zincum.*) The cadmium is separated by dissolving the mixed metal in dilute sulphuric acid, precipitating the sulphate by hydrogen sulphide, treating the precipitate with hydrochloric acid, and again precipitating with ammonium carbonate. The cadmium carbonate thus obtained, after being washed and dried, is mixed with charcoal, and exposed to a dull red heat in an earthen retort, when the reduced metal distils over.

Properties. Cadmium is a white metal, resembling tin, but somewhat heavier and more tenacious. Like that metal, it crackles when bent. Its sp. gr. is 8·7, melting point from 316° to 320° C. (601°–608° F.). It begins to volatilize at a temperature slightly above this, but under the boiling point of mercury, while it boils only at 860° C. (1580° F.). It is little affected by the air, but, when heated, combines with an atom of oxygen, forming a reddish-brown or orange-colored oxide, CdO, which combines with the acids to form salts. From its saline solutions the oxide is precipitated by the alkalies in the form of a white hydrate. Cadmium also combines with chlorine, iodine, bromine, and sulphur. It is distinguished by forming a colorless solution with nitric acid, from which hydrogen sulphide or ammonium sulphydrate precipitates a lemon-yellow sulphide insoluble in an excess of the reagent or in potassa or ammonia, and not volatilized at a red heat. Potassa produces a white precipitate insoluble in an excess, and ammonia a similar precipitate soluble in an excess of the precipitant. Zinc precipitates cadmium in the metallic state. "A neutral solution of the metal in nitric acid, after having been fully precipitated by carbonate of sodium in slight excess, yields a filtrate which is not affected by ammonium sulphide." *U. S.* 1870. This proves the absence of arsenic.

Cadmii Iodidum. Cadmium Iodide. (CdI_2. Mol. wt. 365.) *Cadmium Iodatum. Iodidum Cadmium. Iodure de Cadmium*, Fr. *Iodcadmium, Kadmiumjodür*, G. Cadmium iodide may be prepared by mixing iodine and filings of cadmium in a moist state, or by dissolving the metal in hydriodic acid, or by double decomposition between potassium iodide and cadmium sulphate. It is soluble in water and alcohol, and may be crystallized from either solution, in large, white, transparent crystals, in the form of six-sided tables, of a pearly lustre. These are permanent in the air, melt at about 315·6° C. (600° F.), forming an amber-colored liquid, and give off violet vapors at a dull red heat. The salt is freely soluble in water and in alcohol, and the solution has an acid reaction. The Br. Pharmacopœia of 1867 gives the following tests. The aqueous solution gives a yellow precipitate with hydrogen sulphide or ammonium sulphide, insoluble in excess of the sulphide; and a white gelatinous precipitate with excess of solution of potash, the filtrate from which is unaffected by ammonium sulphide. Ten grains dissolved in water give with an excess of silver nitrate a precipitate which, washed with water and afterwards with half an ounce of water of ammonia and dried, weighs 12·5 grains.

Cadmii Salicylas. Cadmium Salicylate, $Cd(C_6H_4OHCOO)_2$, is prepared by acting on cadmium oxide with salicylic acid. It is colorless and crystalline, soluble in 24 parts of boiling water, and in alcohol, ether, and glycerin. It is used as an antiseptic.

Cadmii Sulphas. Cadmium Sulphate. Cadmium Sulfuricum. Sulfas Cadmicus. Sulfate de Cadmium, Fr. *Schwefelsaures Cadmiumoxyd, Kadmiumsulfat*, G. $CdSO_4,4H_2O$. "Take of Cadmium, in small pieces, *a troyounce;* Nitric Acid *two troyounces;* Sodium Carbonate *three troyounces;* Sulphuric Acid *four hundred and twenty grains;* Dis-

tilled Water *a sufficient quantity*. To the Cadmium and two fluidounces of Distilled Water, contained in a glass vessel, add by degrees the Nitric Acid, and, when the action slackens, apply a gentle heat until the metal is dissolved. Filter the solution, and, having dissolved the Sodium Carbonate in six fluidounces of Distilled Water, mix the solutions thoroughly. Wash the precipitate obtained until the water passes tasteless, and dissolve it in the Sulphuric Acid, diluted with four fluidounces of Distilled Water. Then evaporate the solution to one-third, and set it aside to crystallize. Lastly, dry the crystals on bibulous paper." *U. S.* 1870.

A *cadmium nitrate* is formed first, in consequence of the greater facility with which nitric acid acts upon that metal than sulphuric acid. The cadmium is oxidized at the expense of a part of the acid, with the production of fumes of nitrogen tetroxide, and the resulting oxide unites with the undecomposed part of the acid to form the nitrate. This is then decomposed in solution by sodium carbonate with a mutual interchange of principles; the nitric acid of the cadmium nitrate taking the soda of the carbonate, and forming sodium nitrate which is retained in solution, while the insoluble carbonate of the metal is deposited. This, having been washed, is treated with diluted sulphuric acid, by which the carbonic acid is expelled, and the cadmium sulphate remains in solution, from which it is obtained by concentration and crystallization; or the cadmium is dissolved in dilute sulphuric acid in the presence of nitric acid, according to the reaction: $3Cd_2 + 6H_2SO_4 + 4HNO_3 = 6CdSO_4 + 8H_2O + 4NO$.

Cadmium sulphate crystallizes in oblique prisms with rhomboidal bases, which are transparent and colorless, and said to resemble those of the zinc sulphate. They have an astringent, slightly acidulous, and austere taste, effloresce on exposure to the air, and are very soluble in water. The solution, even though acidulated, gives with hydrogen sulphide a yellow precipitate, becoming orange-yellow, of cadmium sulphide, which is dissolved by strong hydrochloric acid, but is insoluble in solutions of potassa or ammonia, and is thus readily distinguished from the arsenic sulphide. With ammonium sulphide it gives a yellow precipitate insoluble in an excess of the sulphide. Ammonia produces a white precipitate, soluble in an excess of the precipitant; ammonium carbonate a white one insoluble in an excess; potassium ferrocyanide a white precipitate not dissolved by hydrochloric acid; and the ferricyanide a brownish-yellow one soluble in a large excess of that acid. (Brande and Taylor.) By these tests cadmium sulphate is distinguished as a salt of that metal. As a sulphate it is known by yielding a precipitate with barium chloride not soluble in nitric acid. Zinc precipitates cadmium in the metallic state from the solution. Cadmium suspended in a solution of copper sulphate precipitates that metal, leaving cadmium sulphate in solution; and this has been proposed as a method of obtaining the salt.

Medical Uses of Cadmium. It is probable that the insoluble preparations of cadmium are not actively poisonous, but it is certain that the soluble preparations are corrosive poisons, producing symptoms very similar to those caused by the corresponding salts of zinc. The symptoms caused by overdoses are giddiness, vomiting, purging, slowing of the pulse and respiration, loss of consciousness, and spasm. In three cases in which the carbonate is said to have been inhaled, the chief symptoms were constriction of the throat, embarrassed respiration, vomiting and purging, giddiness, and painful spasms. (*Annuaire de Thérap.*, 1859.) For a case of poisoning by the *bromide*, see *Boston Med. and Surg. Journ.*, 1876.

It has been shown by Athanasiu and Langlois (*Compt.-Rend. des Séances et Mémoires de la Soc. Biol.*, ii. 1895) that the soluble salts of cadmium act very powerfully in arresting the lactic fermentation. When given hypodermically to the frog they produce symptoms similar to those caused by zinc salts, than which, however, they are less powerful; the symptoms are rapid loss of voluntary motion with persistence of the reflexes and pronounced cardiac depression. In the higher animals there is destruction of the red blood-corpuscles.

Cadmium sulphate has been used to a considerable extent as a local astringent and stimulant in diseases of the eye and in *gonorrhœa*, and is believed by many oculists to have special power in *relieving specks and opacities of the cornea*. It is employed either in solution, from half a grain to four grains to the fluidounce of distilled water, or in ointment, twelve grains to the ounce.

Cadmium iodide was introduced by A. B. Garrod as an external remedy in the treatment of *scrofulous glands, nodes, chronic inflammations of joints*, and various cutaneous diseases. The ointment, which was formerly official in the British Pharmacopœia under the name of *Unguentum Cadmii Iodidi* (sixty-two grains to one ounce of simple ointment), is soft, white, and said to readily yield its iodine to absorption when applied by persistent gentle friction.

CÆSIUM. The physiological effect of the cæsium chloride has been investigated by S. Botkin. (*Inaug. Diss.*, St. Petersburg, 1888.) He finds that it increases the blood-pressure and retards the heart movement to a slight extent. Laufenauer (*Therap. Monatssch.*, 1889, and *Pester Med. Chirurg. Presse*, 1889) asserts that the cæsium bromide theoretically ought to, and practically does, control *epilepsy* better than do the ordinary bromides. The physiological and medical properties of *rubidium* have also been studied by these investigators and found to resemble those of cæsium. This has led to the putting upon the market, by Merck, of the following preparations:

Rubidium and Ammonium Bromide ($RbBr + 3NH_4Br$). A white or slightly yellowish, crystalline powder, readily soluble in water. Its taste is somewhat cooling at first, and pungently saline afterwards. This salt, one hundred parts of which contain thirty-six parts of rubidium bromide and sixty-four of ammonium bromide (NH_4Br), was especially used by Laufenauer in doses of from one to two drachms (3·88–7·77 Gm.).

Cæsium and Ammonium Bromide ($CsBr + 3NH_4Br$). A white, crystalline powder, readily soluble in water.

Cæsium Carbonate (Cs_2CO_3). Sand-like, white; melting at red heat; very hygroscopic; very soluble in water; soluble also in alcohol.

Cæsium Hydroxide (CsOH). A grayish-white mass melting below red heat; rather deliquescent, behaving towards water or alcohol as potassium hydroxide does.

Cæsium Sulphate (Cs_2SO_4). Anhydrous, colorless prisms, permanent in the atmosphere; extremely soluble in water; insoluble in alcohol.

Also the triple *Cæsium, Rubidium, and Ammonium Bromide.*

CAFFEA. *Coffee. Semen Caffeæ. Café*, Fr. *Kaffee*, G. *Caffè*, It. *Café*, Sp. *Bun*, Ar. *Copi Cotta*, Cingalese. *Kaeva*, Malay. The coffee plant (*Coffea arabica*, Linn.) is a small evergreen tree from fifteen to thirty feet in height. The branches are opposite, the lower spreading, the upper somewhat declining, and gradually diminishing in length, as they ascend, so as to form a pyramidal summit. The opposite leaves are upon short footstalks, oblong-ovate, acuminate, entire, wavy, four or five inches long, smooth and shining, of a dark green color on their upper surface, paler beneath, and accompanied by a pair of small pointed stipules. The flowers are white, with an odor not unlike that of the jasmine, and stand in groups in the axils of the upper leaves. The calyx is very small, the corolla salver-form, with a nearly cylindrical tube, and a flat border divided into five lanceolate, pointed segments. The stamens project above the tube. The fruit, which is inferior, is a roundish berry, umbilicate at top, at first green, then red, and ultimately dark purple. It is about as large as a cherry, and contains two seeds surrounded by a paper-like membrane, and enclosed in a yellowish-purple matter. These seeds, divested of their coverings, constitute coffee.

This tree is a native of Southern Arabia and Abyssinia, and probably pervades Africa about the same parallel of latitude, as it is found growing wild in Liberia, on the western coast of the continent. It is cultivated in various parts of the world where the temperature is sufficiently elevated and uniform. Considerable attention has long been paid to its culture in its native country, particularly in Yemen, in the vicinity of Mocha, from which the demands of commerce were at first almost exclusively supplied. About the year 1690 it was introduced by the Dutch into Java, and in 1718 into their colony of Surinam. Soon after this latter period the French succeeded in introducing it into their West India Islands, Cayenne, and the Isles of France and Bourbon; and it has subsequently made its way into the other West India Islands, various parts of tropical America, Hindostan, and Ceylon.

The tree is raised from the seeds, which are sown in a soil properly prepared, and, germinating in less than a month, produce plants which, at the end of the year, are large enough to be transplanted. These are then set out in rows at suitable distances, and in three or four years begin to bear fruit. It is customary to top the trees at this age, in order to prevent their attaining an inconvenient height, and to increase the number of the fruit-bearing branches. It is said that they continue productive for from thirty to forty years. Though almost always covered with flowers and fruit, they yield most largely at two seasons, and thus afford two harvests during the year. Various methods are employed for freeing the seeds from their coverings; but that considered the best is, by means of machinery, to remove the fleshy portion of the fruit, leaving the seeds surrounded only by their papyraceous envelope, from which they are separated by peeling and winnowing mills.

The character of coffee varies considerably with the climate and mode of culture. Consequently, several varieties exist in commerce, named usually from the sources from which they are derived. The *Mocha Coffee*, which is in small roundish grains, takes precedence of all others. The *Java Coffee* is highly esteemed in this country; but our chief supplies are derived from the West Indies and South America. Some good coffee has been brought from Liberia.* Coffee improves by age, losing a portion of its strength and acquiring a more agreeable flavor. It is said to be much better when allowed to ripen perfectly on the tree than as usually collected. The grains should be hard, and should readily sink in water. When soft, light, black or dark colored, or musty, they are inferior.

Mussaenda Coffee, so called, is not a true coffee, but, according to Lapeyrère, is the seeds of the *Mussaenda borbonica*, or "*wild orange*" of the Island of Réunion, and contains from 0·3 to 0·5 per cent. of caffeine. Prof. Dunstan, however, found no alkaloid in the seeds of *M. borbonica;* whilst, according to the botanists of Kew Gardens, the seeds which Lapeyrère examined were really derived from *Gaertnera vaginata.* (*P. J. Tr.*, Nov. 1889.)

Coffee has a faint, peculiar odor, and a slightly sweetish, somewhat austere taste. An analysis by M. Payen gives for its constituents, in 100 parts, 34 of cellulose, 12 of hygroscopic water, from 10 to 13 of fatty matter, 15·5 of glucose, with dextrin and a vegetable acid, 10 of legumin, 3·5 of *potassium and caffeine chlorogenate*, 3 of a nitrogenous body, 0·8 of free caffeine (see article *Caffeina*), 0·001 of concrete volatile oil, 0·002 of fluid volatile oil, and 6·697 of mineral substances. (*Journ. de Pharm.*, 3e sér., x. 266.) Pfaff recognized, in the precipitate produced by lead acetate with the decoction of coffee, two peculiar principles, one resembling tannin, called *caffe-tannic acid*, and the other an acid, called by him *caffeic acid.* The latter is thought to be identical with the *chlorogenic acid* of Payen. When strongly heated, it emits the odor of roasted coffee, and it is supposed to be the principle to which the flavor of coffee as a drink is owing. A remarkable property of caffeic acid is that, when acted on by sulphuric acid and manganese dioxide, it is converted into quinone, being in this respect analogous to quinic acid. The *sugar* of coffee is probably neither glucose as supposed by Payen, nor cane-sugar as stated by Rochleder, but peculiar; for, when the coffee is roasted, it does not answer to Trommer's test for glucose. Caffe-tannic acid has been ascertained by Hlasiwetz to be a glucoside with the formula $C_{14}H_8O_7$, and resolvable into glucose and a peculiar crystallizable acid, $C_8H_6O_4$, named by him caffeic acid (*Journ. de Pharm.*, 1867, 307), and which may be obtained from coffee by boiling a solution of the extract with caustic potassa, treating the resulting liquid with sulphuric acid in excess, and extracting the caffeic acid with ether, which yields it somewhat impure by evaporation. (*Ibid.*, January, 1868, 75.) Caffeic acid has the constitution of a dihydroxy-cinnamic acid, and on fusion with caustic potash yields protocatechuic and acetic acids. The coffee fat, which ranges in different varieties from 14 to 21 per cent., is, when purified, white, without odor, of a buttery consistence, melting at 37·5° C., and becomes rancid on exposure. According to Rochleder (*Wien. Akad. Ber.*, xxiv. 40), it contains glycerides of palmitic acid and of an acid of the composition $C_{12}H_{24}O_2$.

Coffee undergoes considerable change during the

*Julian E. Walter gives the following results of the analyses of several kinds of unroasted coffee: Java, 0·89 per cent. caffeine; Liberian Java, 1·08 per cent. caffeine; Costa Rica, 1·24 per cent. caffeine; Mocha, 0·54 per cent. caffeine; Peaberry or Fenroll, 0·77 per cent. caffeine; Rio, 1·12 per cent. caffeine. (*Pharm. Rec.*, May 5, 1890, 176.)

roasting process. It swells up very much, acquiring almost double its original volume, while it loses from 15 to 23 per cent. of its weight. (*Pharm. Centralblatt*, 1850, 687.) It acquires, at the same time, a peculiar odor entirely different from that of the unroasted grains, and a decidedly bitter taste. An active empyreumatic oil (*caffeol*, $C_8H_{10}O_2$) is developed during the process, probably at the expense of a portion of the caffeine. Much of the alkaloid, however, escapes change, and a portion of it is volatilized. The excellence of the flavor of roasted coffee depends much upon the manner in which the process is conducted, and the extent to which it is carried. It should be performed in a covered vessel, over a moderate fire, and the grains should be kept in constant motion. When they have acquired a chestnut-brown color, the process should cease. If too long continued, it renders the coffee bitter and acrid, or, by reducing it to charcoal, deprives it entirely of flavor. During a severe roasting the coffee loses a portion of caffeine, which sublimes; while in a slight roasting it loses none: yet ordinary coffee for drinking, prepared by percolation, contains rather more caffeine when prepared from strongly roasted than from slightly roasted coffee, because the caffeine is more easily extracted from the former. (Herman Aubert. See *A. J. P.*, 1873, 121.) The coffee should not be roasted long before it is used, and should not be kept in the ground state. Paul and Cownley found in preparing "low and medium roasted" coffee no perceptible loss of alkaloid, whilst in "over-roasted" coffee the loss amounted to one-third. The average amount of caffeine in moderately roasted coffee they fix at 1·3 per cent. (*P. J. Tr.*, 1887, 822.)

The *leaves* of the coffee plant possess properties analogous to those of the fruit, and are extensively used by the Malays. Dr. Stenhouse found them to contain caffeine in larger proportion than the coffee-bean, and also caffeic acid. The leaves are prepared for use by drying over a clear fire and then powdering by rubbing in the hands. The powder is made into an infusion like common tea. The taste is said to be like that of tea and coffee combined. (*P. J. Tr.*, xii. 443, xiii. 207 and 382, and xvi. 1067.)

For its activity coffee depends chiefly upon the presence in it of caffeine, for the physiological and therapeutic action of which, see page 283. According to Paul and Cownley, a cup of coffee (f℥iii), prepared by percolation through half an ounce of coffee, contains a little less than two and a half grains of caffeine. (*P. J. Tr.*, April, 1887.) The ordinary effects of coffee taken into the stomach are too well known to require description; as an exhilarant and cerebral stimulant it is one of the most efficacious of the caffeinic drinks. It differs from many of these drinks, however, in having a tendency to derange digestion and to act upon the bowels, so that in cases of chronic or acute diarrhœa its use frequently has to be forbidden. Its habitual excessive use may give rise to troublesome dyspepsia, to cardiac irritability, or to headache, and even to vertigo. The caffeinic headache is well recognized by the profession, and is only to be cured by abstinence from its cause. These disagreeable symptoms are much more apt to be produced by coffee than by tea; indeed, although the active principle of these drinks is probably the same, their action upon the human system, although very similar, is not identical. The reason of the difference is not evident. It has been supposed to be due to the empyreumatic oil of coffee, *caffeol* or *caffeone*, but the researches of Prof. E. T. Reichert seem to lead to a different conclusion. (*Med. News*, lvi. 1890.) It is probable that some active principle, volatile or otherwise, is formed during the process of roasting, or caffeic acid may be active. Coffee has been used in times past in various diseases, but as a medicine it has been replaced by caffeine. Roasted coffee, especially in the form of powder, has long been known to have some disinfecting and deodorizing power. Leuderitz has found that this is based upon a feeble though positive influence exerted upon bacteria; this influence being probably dependent upon the presence of the empyreumatic substances formed during the roasting.

Coffee is usually prepared in this country by boiling the roasted grains, previously ground into a coarse powder, in water for a short time, and then clarifying by the white of an egg. Some prefer the infusion, made by a process similar to that of percolation. It has more of the aroma of the coffee than the decoction, with less of its bitterness. The proper proportion for forming the infusion for medical use is an ounce to a pint of boiling water, of which a cupful may be given warm for a dose, and repeated, if necessary. A *syrup of coffee* is prepared by Dorvault in the following manner. Treat a pound of ground roasted coffee by percolation with boiling water until two pints have passed. Evaporate eight pounds of simple syrup to six, add the infusion, and strain. Two tablespoonfuls of this syrup may be added to a cup of hot water or milk. It is also used with carbonic-acid water.

CAHINCA. *Radix Caincæ. Radix Cainanæ. Cainça*, Fr. *Caincawurzel*, G. This medicine attracted at one time considerable attention. The name of *cahinca* or *cainca* was adopted from the language of the Brazilian Indians. The Portuguese of Brazil call the medicine *raiz pretta*, or *black root*. When first noticed in Europe, it was supposed to be derived from the *Chiococca racemosa* of Linnæus, which was known to botanists as an inhabitant of the West Indies. But Martius, in his *Specimen Materiæ Medicæ Brasiliensis*, describes two other species of *Chiococca*, *C. anguifuga*, Mart., and *C. densifolia*, Mart., both of which are now known as *C. brachiata*, Ruiz and Pav., which afford roots having the properties of the root ascribed to *C. racemosa;* and, as the medicine was brought from Brazil, there seemed to be good reason for referring it to one or both of the plants named by that botanist. A. Richard, however, received from Brazil specimens of *C. racemosa* as the cahinca plant.

A specimen brought into this market consisted of cylindrical pieces, varying in size from the thickness of a straw to that of the little finger, somewhat bent or contorted, slightly wrinkled longitudinally, with occasional small asperities, internally ligneous, externally covered with a thin, brittle, reddish-brown bark, having a light brown or brownish ash-colored epidermis. The cortical portion, which was of a resinous character, had a bitter disagreeable taste, somewhat acrid and astringent; the ligneous part was quite tasteless. The virtues of the root reside almost exclusively in its bark. They are extracted by water and alcohol. Cahinca has been analyzed by several chemists. Four distinct principles were discovered in it by

Pelletier and Caventou,—1, a crystallizable bitter substance, believed to be the active principle, and called *cahincic acid*, $C_{40}H_{64}O_{18}$; 2, a green fatty matter of a nauseous odor; 3, a yellow coloring matter; and 4, a colored viscid substance. Rochleder and Hlasiwetz found also caffe-tannic acid. By these chemists a tincture, obtained by boiling the bark in alcohol, was precipitated first with a spirituous solution of lead acetate, and afterwards, having been previously filtered, with the tribasic lead acetate. The first precipitate consisted chiefly of lead caffe-tannate and a portion of lead cahincate, the second of lead cahincate exclusively. Cahincic acid is white, without smell, of a taste at first scarcely perceptible, but afterwards extremely bitter and slightly astringent, of difficult solubility in water, but readily soluble in alcohol, permanent in the air, and unaltered at 100° C. (212° F.). It reddens vegetable blues, and unites with the alkalies, but does not form crystallizable salts. It is thought to exist in the root as calcium subcahincate. When treated with diluted hydrochloric acid it is decomposed into glucose and other products, of which is obtained at first *chiococcaic acid*, $C_{28}H_{42}O_7$ (thought by some to be identical with *quinovic acid*), and later, by prolonged boiling with alcoholic hydrochloric acid, *caïncetin*, $C_{22}H_{34}O_3$.

Medical Properties.—Cahinca is tonic, diuretic, purgative, and emetic. In moderate doses it gently excites the circulation, increases the discharge of urine, and produces evacuations from the bowels, but is rather slow in its operation. It may be made to act also as a diaphoretic, by keeping the skin warm, using warm drinks, and counteracting its purgative tendency. In some patients it occasions nausea and griping, and in very large doses always acts powerfully both as an emetic and cathartic. In Brazil it has long been used by the natives as a remedy for the *bites of serpents;* and its Indian name is said to have been derived from this property. According to Martius, the bark of the fresh root is rubbed with water till the latter becomes charged with all its active matters; and the liquid, while yet turbid, is taken in such quantities as to produce the most violent vomiting and purging, preceded by severe spasmodic pains. Patrick Brown speaks of the root of *C. racemosa* as very useful in obstinate *rheumatism*. But the virtues of cahinca in *dropsy*, though well known in Brazil, were first made known to the European public in the year 1826 by M. Langsdorf, Russian consul at Rio Janeiro. Achille Richard, François, and other practitioners attested its value in *dropsy*, but it is now little used. Dose of the powdered bark, from twenty grains to a drachm (1·29–3·88 Gm.); of the aqueous or spirituous extract, from ten to twenty grains (0·648-1·29 Gm.).

CALAMINA. *Calamine. Lapis Calaminaris.* Calamine is the old name of the native zinc carbonate, although, strictly speaking, the name of the mineral *Calamine* is now applied to zinc silicate, while the name *Smithsonite* is given to the carbonate. It is found in the United States, as well as in Belgium, Germany, and England. It occurs in compact or earthy masses, or concretions, of a dull appearance, readily scratched by the knife, and breaking with an earthy fracture, or it occurs crystallized in rhombic forms. Its color is very variable; being, in different specimens, grayish, grayish yellow, reddish yellow, and, when very impure, brown or brownish yellow. Its sp. gr. varies from 3·4 to 4·4. Before the blow-pipe it does not melt, but becomes yellow and sublimes. When of good quality, it is almost entirely soluble in the dilute mineral acids; and, unless it has been previously calcined, emits a few bubbles of carbonic acid. If soluble in sulphuric acid, it can contain but little calcium carbonate and no barium sulphate.

Prepared Calamine. Calamina Præparata. Calamine must be impalpable before being used in medicine. The following is the U. S. formula of 1850. "Take of Calamine a convenient quantity. Heat it to redness, and afterwards pulverize it; then reduce it to a very fine powder in the manner directed for Prepared Chalk." The object of this process is to reduce the native zinc carbonate, or calamine, to the state of an impalpable powder. Calamine, as sold in England and the United States, was formerly almost always spurious, consisting wholly or principally of barium sulphate, colored with ferric oxide. Of the six samples analyzed by Ferris Bringhurst, of Wilmington, Del., five were totally devoid of zinc, and the sixth contained only 2 per cent. of the oxide. (*A. J. P.*, July, 1857.) But more recently (*P. J. Tr.*, 1866), Mr. R. H. Davis has found that most of the calamine sold as such in Great Britain is genuine. Prepared calamine is in the form of a pinkish or flesh-colored powder, of an earthy appearance. Sometimes it is made up into small masses. It is used only as an external application, being employed as a mild astringent and desiccant in *excoriations* and *superficial ulcerations*. For this purpose it is usually dusted on the part, and hence the necessity for its being in very fine powder. It is often employed in the form of cerate.

CALCII BENZOAS. *Calcium Benzoate.* $Ca(C_7H_5O_2)_2 + 3H_2O$. This salt may be made by adding calcium carbonate to a hot aqueous solution of benzoic acid, filtering, and evaporating the solution, and collecting and drying the crystals, which usually form in beautiful radiating tufts. It is soluble in 18 parts of cold water and 6 parts of boiling water. *Calcium Hippurate*, $Ca(C_9H_8NO_3)_2 + 3H_2O$, is made in a similar manner, and is identical in appearance and uses. Poulet recommends the latter highly in the *uric acid diathesis*, for *scrofula*, incipient *cirrhosis of the liver*, and in *struma*. Dose, ten grains (0·648 Gm.).

CALCII BORAS. $Ca_3(BO_3)_2$. *Calcium borate* is prepared by mixing solutions of sodium borate and calcium chloride. It is a white, inodorous, tasteless powder. It is given internally in *diarrhœa*, and used externally as a deodorant and antiseptic.

CALCII HYPOSULPHIS. *Calcium Sulphosulphate* or *Thio-sulphate. Calcium Hyposulphite.* $CaS_2O_36H_2O$. The following mode of preparing this salt is recommended by M. J. Laneau, of Paris. Take 1000 parts of sulphur, 400 of lime, and 4000 of rain-water; slake the lime with sufficient of the water, add the sulphur and the residue of the water, and boil for an hour and a half, adding water to keep up the measure; when cool filter the liquid through linen covered with filtering paper, and wash the residue with 1000 parts of water. A solution is thus obtained of calcium polysulphide of the sp. gr. 1·141. Into this pass a current of washed sulphurous acid gas until the solution becomes colorless; separate the precipitated sulphur (which may be used for the official *Precipitated Sulphur*); and evaporate the clear solution at a

heat not exceeding 60° C. (140° F.), until it begins to crystallize, when it is to be set aside. The product is 700 parts of calcium hyposulphite. This is in six-sided crystals, which effloresce in a dry air. M. Laneau prepares a syrup of the hyposulphite by dissolving 10 parts of the crystallized salt in 20 parts of distilled water, and mixing with the solution 170 parts of syrup of orange flowers. (See *A. J. P.*, 1863, 223.) The dose of the salt is from ten to twenty grains three times a day, of the syrup from two to four fluidrachms.

Of the *hyposulphites*, generally, it may be said that they closely resemble the sulphites in medical properties, and may be employed as substitutes for those salts, over which they have the advantage of greater stability, passing less readily into sulphates on contact with the air. They may be prepared by boiling a sulphite or bisulphite for some time with sulphur. They are very soluble in water, and are recognized by the precipitation of sulphur when decomposed by an acid.

CALCII IODIDUM. *Calcium Iodide. Calcium Iodatum. Iodure de Calcium*, Fr. *Jodcalcium, Calcium Jodid*, G. CaI_2. According to M. Malem (*Bull. Thérap.*, Avril 30, 1868), this salt is preferable to any other iodic compound in *phthisis*. Malem prepares it by treating a solution of ferrous iodide with milk of lime. This liquor thus obtained, being filtered and evaporated, yields crystals of calcium iodide. It may also be made by dissolving lime or its carbonate in hydriodic acid. Pure calcium iodide is white, and crystallizes in large plates of a pearly lustre. Procured as recommended, it is yellowish, probably in consequence of the presence of iodine in excess. It is deliquescent, and very soluble in water, and its solution is capable of dissolving iodine added to it. Calcium iodide is much more unstable than potassium iodide. When taken, it is rapidly decomposed into hydriodic acid and salts of lime, which are almost immediately absorbed. Most patients bear it very well. From one to three or four grains may be given after each meal. (*Ann. de Thérap.*, 1869, 194.) To make the syrup of calcium iodide the following formula has been proposed by Mr. O. Eberbach (*P. J. Tr.*, 3d ser., i. 364). Take of iodine 4 oz.; iron (in form of wire) 7½ dr.; distilled water q. s.; milk of lime (fresh) q. s.; sugar 28 oz.; simple syrup q. s.; mix 3 oz. of the iodine with the iron and 4 oz. of water, in a thin flask with long neck; shake occasionally until the reaction has ceased and the solution assumes a pale green color; filter the solution, and add the remainder of the iodine; heat to the boiling-point, and add milk of lime until all of the iron is precipitated. Filter, and wash the precipitate with hot water until all the iodide is washed out, and then bring the whole to the measure of 20 fl. oz.; add the sugar, and dissolve by a gentle heat; to the solution add enough simple syrup to make it measure 40 fl. oz.; mix thoroughly, and fill into 2-oz. bottles well corked. Stanislaus Martin prepares the syrup by triturating 5 parts of calcium hydrate in a mortar with 30 parts of sugar, adding 100 parts of water in small portions at a time, allowing it to stand several hours; filtering, adding 2 parts of iodine, and when this is dissolved, 170 parts more of sugar, and flavoring with orange-flower water. (*P. J. Tr.*, 1875, 299.)

CALCII PERMANGANAS. *Calcium Permanganate.* $CaMn_2O_8$. This salt probably has the same physiological and medical properties as the corresponding salt of potassium. It has been used in *gastro-enteritis* and *diarrhœa* in doses of from one-half to one and a half grains, but has been especially urged for the purification of water. For spring water twenty milligrammes, for river water forty milligrammes, per litre are recommended. If the water becomes red the permanganate is in excess.

CALCII SALICYLAS. $CaC_7H_4O_3 + H_2O$. This compound is the basic calcium salt. It is a sandy, white powder, almost insoluble in water. It is formed when an excess of milk of lime is used. The neutral salt is also known and is quite soluble in water. *Calcium salicylate* has been used in Austria in doses of from seven to twenty grains (0·453–1·29 Gm.), for *diarrhœa* and *gastro-enteritis*. For method of preparation, see *P. J. Tr.*, vol. xxii., 1891.

CALCIUM IODATE. $Ca(IO_3)_2 5H_2O$. *Iodate de Chaux*, Fr. *Iodsaurer Kalk*, G. This salt has been brought forward by E. Sonstadt as a valuable antiseptic, to be used in the preservation of food. (*Chem. News*, xxviii. 297; confirmed in *Provincial Med. Journ.*, March, 1890.) S. W. Moore states that it is a useful antipyretic. (*Am. Journ. Med. Sci.*, lxx. 190.) It exists in sea-water, but may be prepared by acting upon iodine with chlorinated lime. (*A. J. P.*, 1874, 558.)

CALI NUTS. These nuts, which come from the west coast of Africa, are the seeds of a papilionaceous plant, and have a more circular shape than Calabar beans, but otherwise agree with the latter in essential external characters. They contain an alkaloid which is said to be chemically and physiologically closely allied to physostigmine. (Merck, *Chem. Centralb.*, 1887.)

CALLITRICHE VERNA. L. (Now *C. palustris.* L.) (Nat. ord. Callitrichaceæ.) *Water Starwort.* This indigenous water-plant is given in decoction in *dropsical* and *urinary affections*.

CALOTROPIS GIGANTEA. Dryand. *Asclepias gigantea.* Willd, *Madar* or *Mudar*, of the East Indies, is the bark of the root of a species of Calotropis, generally considered as *C. gigantea*, but asserted by Dr. Casanova to be a distinct species, and named by him *C. Madarii Indico-orientalis. C. gigantea* is a native of Hindostan, but is naturalized in the West Indies. The bark, as employed, is without epidermis, of a whitish color, nearly or quite inodorous, and of a bitter somewhat nauseous taste. According to C. J. H. Warden and L. A. Waddel, it contains an acid resin, a crystalline colorless substance, *madaralban*, an amber-colored viscid body, *madarfluavil*, and caoutchouc. (*P. J. Tr.*, 1885, 165.) It appears to have the general properties of many other acrid medicines; in small doses increasing the secretions, and in larger, producing nausea and vomiting. It has been very largely used as a local remedy in Hindostan in *elephantiasis* and *leprosy;* and in the form of a poultice of its leaves it is asserted by John Morton (*Indian Medical Record*, viii., 1895) to act with extraordinary efficiency upon chronic *eczema*. It has also been employed internally as a remedy in *diarrhœa* and *dysentery;* also with less probability of usefulness in *syphilis* and *rheumatism*. Dose of powder, from three to twelve grains (0·194–0·775 Gm.), three times a day, gradually increased till it affects the system.

The root of the *Calotropis procera* closely resem-

bles that of the *C. gigantea*, and probably has similar medicinal properties. The milky juice of both of these plants is said to be habitually used in India for killing female infants. (See *P. J. Tr.*, vol. xvi. 166.) The plant has of late years been applied to various economical purposes in India. The most important of these is the manufacture of cords, ropes, etc., from the fibres of its branches, which are said to possess many of the properties of flax.

CALYCANTHUS GLAUCUS. Willd. (*Butneria fertilis* (Walt.), Kearney, in Britton and Brown's *Flora*.) This is a shrub of the nat. ord. Calycanthaceæ, from six to eight feet high, with rather rigid ovate or ovate-lanceolate, acuminated leaves, from four to seven inches long; with purplish-brown or chocolate-colored flowers, nearly two inches in diameter, and having lanceolate and abruptly sharp-pointed sepals and petals. It inhabits the low, shady woods along the mountains of Georgia and North Carolina, and also Tennessee, where it is known as *sweet shrub or bubby*. According to R. G. Eccles, the seeds contain a fixed oil, and an alkaloid, *calycanthine*, of unknown physiological properties. Dr. H. W. Wiley (*A. J. P.*, 1890, 96) found in the seeds over 47 per cent. of oil and notable quantities of sugars (dextrose, sucrose, and dextrin); also 4·25 per cent. of alkaloid. This latter crystallizes from ether in feathery crystals. The whole plant is aromatic, having when crushed the odor of strawberries.

CAM WOOD. A red dye-wood, procured from the *Baphia nitida*, Lodd, a leguminous tree, growing on the western coast of Africa. The wood is usually kept in the shops in the ground state. It yields its coloring matter scarcely at all to cold water, slightly to boiling water, and readily to alcohol and alkaline solutions. The coloring matter is thought to be identical with santalin, $C_{15}H_{14}O_5$.

CANARY SEED. *Fructus* (*Semen*) *Canariense. Semence de Canarie*, Fr. *Kanariensamen*, G. The seeds of *Phalaris Canariensis*, L., an annual grass originally from the Canary Islands, but now growing wild in Europe and the United States. The seeds are ovate, somewhat compressed, about two lines long, shining, and of a light yellowish-gray color externally and brownish within. Their chief constituent is starch, and they are now used chiefly as a bird-seed.

CANCHALAGUA. This plant, *Erythræa venusta*, A. Gray (nat. ord. Gentianaceæ), found on our Pacific coast, is a valuable bitter tonic and stomachic. (*Pharm. Record*, 1887, 363.) *Erythræa australis*, R. Br., is said to be similarly used in Australia. (*P. J. Tr.*, xix.)

CANELLA. The bark of *Canella alba*, Murray, was formerly recognized by both Pharmacopœias. The tree rises sometimes to the height of fifty feet, branching only at the top, and is covered with a whitish bark and alternate, petiolate, oblong-obtuse, entire, dark green, fragrant leaves. The flowers are small, clustered, and of a violet color. The fruit is an oblong berry, containing one, two, or three black, shining seeds.

Canella alba is a native of Florida and the Bahama and West India Islands. The bark of the branches, which is the part employed in medicine, is loosened and deprived of its epidermis by beating. After removal from the tree it is dried in the shade. It enters commerce solely from the Bahamas, where it is known as *cinnamon bark*, or as *white wood bark*. It occurs in pieces partially or completely quilled, occasionally somewhat twisted, of various sizes, from a few inches to two feet in length, from half a line to two or even three lines in thickness, and, in the quill, from half an inch to an inch and a half in diameter.

Canella is of a pale orange-yellow color externally, yellowish white on the inner surface, with an aromatic odor somewhat resembling that of cloves, and a warm, bitterish, very pungent taste. It is brittle, breaking with a short fracture, and yielding, when pulverized, a yellowish-white powder. Boiling water extracts nearly one-fourth of its weight; but the infusion, though bitter, has comparatively little of the warmth and pungency of the bark. It yields all its virtues to alcohol, forming a bright yellow tincture, which is rendered milky by the addition of water. By distillation with water it affords a large proportion of a yellow or reddish, fragrant and very acrid volatile oil. It contains, moreover, according to the analysis of MM. Petroz and Robinet, mannite, a peculiar very bitter extractive, resin, gum, starch, albumen, and various saline substances. Meyers and Reiche obtained twelve drachms of the volatile oil from ten pounds of the bark. They found it to consist of four different oils, the first being identical with the eugenol or eugenic acid of oil of cloves; the second is closely allied to the chief constituent of cajuput oil; the other oils require further examination. The bark yielded to Flückiger 0·74 per cent. of oil. Meyers and Reiche also obtained 8 per cent. of mannite and 6 per cent. of ash, chiefly calcium carbonate. Canella has been sometimes confounded with Winter's bark, from which, however, it differs widely. (See *Wintera*.) According to Mr. John P. Frey, it contains volatile oil, 1·28 per cent.; resin, 8·2 per cent.; mannite, 8 per cent.; ash, 8·9 per cent.; also starch, bitter principle, albumen, and cellulose. (*A. J. P.*, 1884, 1.) It is a mild, aromatic tonic, very acceptable to the stomach, and especially as an addition to tonic or purgative medicines. It is scarcely ever prescribed except in combination. In the West Indies it is employed by the negroes as a condiment, and has some reputation as an antiscorbutic. Dose, from ten to forty grains (0·65–2·6 Gm.).

CANGOURA. An evergreen creeper, from the seeds of which the natives of Salvador are said to produce a paste which is a violent nerve poison, producing in some cases delirium lasting as long as eight days. (*Les Nouv. Remèd.*, Avril, 1892.)

CAOUTCHOUC, ARTIFICIAL. Prof. Sonnenschein has discovered that an elastic mass resembling caoutchouc may be obtained by combining sodium tungstate with certain organic substances. If tungstic acid or the sodium tungstate be added to a solution of glue and afterwards hydrochloric acid, a compound of tungstic acid glue is precipitated, which is so elastic at from 29·4° C. (85° F.) to 40·5° C. (105° F.) that it can be drawn out into very thin fibres. On cooling, the mass becomes very solid and brittle. (*A. J. P.*, xliii. 471.) Within recent years many attempts have been made to make artificial rubber by the vulcanization of fatty oils with either sulphur or sulphur chloride. Linseed oil, cotton-seed oil, and the fish oils have all been used for this purpose with varying success. Latterly it is asserted that very successful results have been attained by the vulcanization of maize oil.

CAPPARIS SPINOSA. L. *Caper-bush.* (Nat. ord. Capparideæ.) A low, trailing shrub, growing in the south of Europe and north of Africa. The buds or unexpanded flowers, treated with salt and vinegar, form a highly esteemed pickle, which has an acid, burning taste, and is considered useful in scurvy. The dried bark of the root was formerly official. It is in pieces partially or wholly quilled, about one-third of an inch in mean diameter, transversely wrinkled, grayish externally, whitish within, inodorous, and of a bitterish, somewhat acrid, and aromatic taste. It contains *rutic acid* and a volatile substance of garlic-like odor. It is considered diuretic, and was formerly used in *amenorrhœa* and *chronic rheumatism.*

CAPSELLA BURSA-PASTORIS. Medic. *Shepherd's Purse. Thlaspi Bursa-Pastoris.* Linn. *Bursa-Pastoris.* Weber. *Bursa Bursa-Pastoris* (L.). Britt. *Bourse à Pasteur, Molette,* Fr. *Hirtenäschlein,* G. (Nat. ord. Cruciferæ.) This very common weed is bitter and pungent, yields on distillation a volatile oil identical with oil of mustard, and, according to E. Bombelon, contains an alkaloid, *bursine.* (See *A. J. P.*, 1888; also *Provincial Med. Journ.*, 1858.) It has been used as an antiscorbutic, also in *hæmaturia* and other *hemorrhages,* and in *amenorrhœa* and *dropsy.* From two to four fluidounces (59·14–118·2 C.c.) of the fresh expressed juice may be given at a dose; or from a quarter to a half fluidrachm (0·92–1·85 C.c.) of the fluid extract of the dried plant.

CAPTOL. This is a proprietary preparation, and is said to be of variable composition, but is in the main a condensation product of tannin and chloral. It is a brown hygroscopic powder, slightly soluble in cold water, very soluble in hot water and alcohol, not altered by acids but decomposed by alkalies, striking a dark color with ferric salts. It has been very strongly recommended by Eichhoff in *seborrhœa capitis.* The head is to be washed morning and evening with a 1 to 2 per cent. alcoholic solution of captol.

CARANNA. *Gum Caranna.* A resinous substance, in pieces of a blackish-gray color, externally dark brown, internally somewhat shining and translucent, brittle and pulverizable when dry, but, in the recent state, soft and adhesive, like pitch, easily fusible, of an agreeable balsamic odor when heated, and of bitterish resinous taste. (Geiger.) It is said to be derived from the *Amyris Caranna* of Humboldt (now *Protium Caranna,* March.), a tree growing in Mexico and South America. Geiger refers it also to *Bursera gummifera,* L., of the West India Islands; but the resin obtained from this tree is described by the French writers under the name of *resine de Gomari* or *resine de chibou* or *cachibou,* and is said to bear a close resemblance to the resin *tacamahac.* It is probable that in different parts of South America the name Caranna is applied to the products of different trees. (*A. J. P.*, xli. 233.)

CARDAMINE PRATENSIS. L. *Cuckoo-flower. Herba Nasturtii Pratensis. Cresson des Prés,* Fr. *Wiesenkresse, Kukukskraut,* G. This is a perennial herbaceous plant, of the nat. ord. Cruciferæ, with a simple, smooth, erect stem, about a foot in height. The leaves are pinnate, the radical composed of roundish irregularly toothed leaflets, those of the stem alternate, with leaflets which become narrower, more entire, and pointed as they ascend. The flowers are purplish white or rose-colored, and terminate the stem in a raceme approaching the character of a corymb. The plant is a native of Europe, and is found in the northern parts of our continent, extending from Labrador to New Jersey, and west to Minnesota and the Pacific coast of British America. The bitterish and slightly pungent leaves are supposed to be antiscorbutic. The seeds are said to contain *myronic acid,* and to yield on decomposition an oil analogous to oil of mustard. In Europe they are sometimes added to the salads. The flowers have the same taste as the leaves, and, when fresh, a somewhat pungent odor. When dried they become inodorous and nearly insipid. They formerly possessed the reputation of being diuretic, and of being useful in *chorea* and *asthma.*

CARISSIN. This is a glucoside which has been isolated from the bark *Carissa ovata,* R. Br. (nat. ord. Apocynaceæ), by J. H. Maiden and H. G. Smith. It is stated to be exceedingly bitter and very poisonous, and in its chemical relations to resemble strophanthin, from which it differs, however, in being precipitated by basic acetate of lead and by tannic acid. Its most characteristic reaction is the production of a beautiful emerald-green color on the addition of a minute fragment of potassium bichromate to its solution in concentrated sulphuric acid. (*P. J. Tr.*, 1896.)

CARNALLITE. This mineral, found in Stassfurt, Prussia, is very extensively used in the preparation of potassium salts. It is a double magnesium and potassium chloride, associated with rock salt. (See *P. J. Tr.*, March, 1872, 787.) The amount of carnallite mined reached a maximum in 1882, when it was 1,059,300 tons. In 1897 it amounted to 950,367 metric tons, valued at $3,019,848.

CARNAUBA ROOT. This root, the product of *Corypha cerifera,* a wax palm of Brazil, is several feet in length, about three-eighths of an inch thick, with a thick friable cortex of a mixed grayish and reddish-brown color. (*A. J. P.*, 1875, 349.) Mr. E. L. Cleaver found in it tannic acid, an acrid resinous body, a red coloring matter, and a minute portion of volatile oil and of an alkaloid. (*P. J. Tr.*, 1875, 965.) It is said to act like sarsaparilla.

CAROTA. *U. S.* 1870. *Daucus Carota.* L. *Carotte,* Fr. *Gemeine Mohre, Gelbe Rübe,* G. *Carota,* It. *Lanahoria,* Sp. (Nat. ord. Umbelliferæ.) The *wild carrot* has a biennial, spindle-shaped root, and an annual, round, furrowed, hairy stem, which divides into long, erect, flower-bearing branches, and rises two or three feet in height. The leaves are hairy and stand on footstalks nerved on their under side. The lower are large and tripinnate; the upper, smaller and less compound; in both, the leaflets are divided into narrow pointed segments. The flowers are small, white, and disposed in many-rayed compound umbels, which are at first flat on the top and spreading, but when the seeds are formed, contract so as to present a concave cup-like surface. A sterile flower, of a deep purple color, is often observable in the centre of the umbel. The general involucrum is composed of several leaves, divided into long narrow segments; the partial is more simple. The petals are five, unequal, and cordate. The fruit consists of two plano-convex hispid portions, connected by their flat surfaces. *Daucus carota* is exceedingly common in this country, growing along fences, and in neglected fields. It grows wild also in Europe. The well-known garden carrot is the same plant somewhat altered by cultivation. The seeds or

fruits are very light, of a brownish color, an oval shape, flat on one side and convex on the other, and on their convex surface present four longitudinal ridges, to which stiff, whitish hairs or bristles are attached. They have an aromatic odor, and a warm, pungent, and bitterish taste. By distillation they yield a pale yellow volatile oil, upon which their virtues chiefly depend. The root of the wild plant may be substituted for the seeds. The root of the wild carrot is whitish, hard, coriaceous, branched, of a strong smell, and an acrid, disagreeable taste; that of the cultivated is reddish, fleshy, thick, conical, rarely branched, of a pleasant odor, and a peculiar, sweet, mucilaginous taste. The constituents of the root are crystallizable and uncrystallizable sugar, a little starch, extractive, gluten, albumen, volatile oil, vegetable jelly or *pectin*, malic acid, saline matters, lignin, and a peculiar crystallizable, ruby-red, neutral principle, without odor or taste, called *carotin*. According to Husemann, its formula is $C_{18}H_{24}O$. It forms reddish-brown, golden-green, lustrous quadratic crystals, fusing at 167·8° C., easily soluble in carbon disulphide, difficultly soluble in alcohol and ether; dissolving in concentrated sulphuric acid with violet or blue color; colored by sulphurous oxide blue. Husemann has also described a colorless compound, *hydrocarotin*, $C_{18}H_{30}O$, which exists with carotin in the juice of the carrot, and is probably changed into the latter by oxidization as the plant develops in growth. According to MM. Frorde and Sœauer, carotin, as well as the modification which has been named *hydrocarotin*, is in fact *cholesterin* colored by a red pigment (*A. J. P.*, 1866, 505), but Husemann seems to have disproved this assertion. Arnaud (*Compt.-Rend.*, cii. 1319), however, isolated cholesterin from carrots, which, after repeated purifying with alcohol, was obtained crystallized in leaflets with 1 mol. of water. It melts at 136·5° C., losing the 1 mol. of water. It seems to be identical with the cholesterin obtained by Hesse from Calabar beans and from peas, and differs only very slightly from animal cholesterin. The substance called *vegetable jelly* was by some considered a modification of gum or mucilage, combined with a vegetable acid. Braconnot found it to be a peculiar principle, and named it *pectin*, from the Greek (πηκτις), expressive of its characteristic property of gelatinizing. It exists more or less in all vegetables, and is abundant in certain fruits and roots from which jellies are prepared. It may be separated from the juice of fruits by alcohol, which precipitates it in the form of a jelly. This, being washed with weak alcohol and dried, yields a semi-transparent substance bearing some resemblance to ichthyocolla. Immersed in 100 parts of cold water, it swells like bassorin, and ultimately forms a homogeneous jelly. With a larger proportion it exhibits a mucilaginous consistence. It is less acted on by boiling than by cold water. When perfectly pure it is tasteless, and has no effect on vegetable blues. A striking peculiarity is that, by the agency of a fixed alkali or alkaline earthy base, it is instantly converted into pectic acid, which unites with the base to form a pectate. This may be decomposed by the addition of an acid, which unites with the base, and separates the pectic acid. *Pectic acid* thus obtained is in the form of a colorless jelly, slightly acidulous, with the property of reddening litmus paper, scarcely soluble in cold water, more soluble in boiling water, and forming with the latter a solution, which, though it does not become solid on cooling, is coagulated by alcohol, lime water, acids, or salts, and even by sugar if allowed to stand for some time. With the alkalies it forms salts, capable of gelatinizing; with the earths and metallic oxides, insoluble salts. Braconnot thinks that pectic acid exists in many plants already formed. M. Frémy found that pectin results, in fruits, from the reaction of acids upon a peculiar insoluble substance they contain when immature, called by him *pectose;* and that pectin is changed into pectic acid not only by alkalies, but also by vegetable albumen. Carrot seeds are slightly aromatic, moderately excitant and diuretic, and are employed in *chronic nephritic affections*, *dropsy*, and in the *strangury* from blisters. From thirty grains to a drachm (1·94–3·88 Gm.) of the bruised seeds may be given at a dose, or a pint of the infusion, containing the virtues of half an ounce or an ounce of the seeds, may be taken during the day. The whole umbel is often used instead of the seeds alone. The scraped root of the garden plant was formerly used as a stimulant application to phagedenic, sloughing, ill-conditioned, and even *cancerous ulcers*. Boiled and mashed, the root is perfectly mild, and fit only to form emollient cataplasms. An ointment was prepared by the late Prof. Procter as follows. Take of grated carrot root half a pound, lard a pound, wax four ounces. Melt the lard and wax, add the carrot root, evaporate with a moderate heat the moisture of the root, and strain.

CARTHAMUS. *Carthamus Tinctorius.* L. (Nat. ord. Compositæ.) The *African*, *false*, *American*, or *dyers' saffron* is an annual plant, with a smooth, erect stem, somewhat branched at top, and a foot or two in height. The leaves are alternate, sessile, ovate, acute, entire, and furnished with spiny teeth. The flowers are compound, in large terminal, solitary heads. The florets are of an orange-red color, with a funnel-shaped corolla, of which the tube is long, slender, and cylindrical, and the border divided into five equal, lanceolate, narrow segments. The plant is a native of India, the Levant, and Egypt, and is cultivated in those countries, as well as in various parts of Europe and America. The florets are brought to us chiefly from the ports of the Mediterranean. *Safflower* (*Flores Carthame; Fleurs de carthame*, *Safran bâtard*, Fr.; *Safflor*, G.; *Cartamo*, It., Sp.) in mass is of a red color, diversified by the yellowness of the filaments contained within the floret. It has a peculiar slightly aromatic odor, and a scarcely perceptible bitterness. It contains two coloring substances,—one red, insoluble in water, slightly soluble in alcohol, very soluble in alkaline liquids, and called *carthamin* or *carthamic acid* by Döbereiner, who found it to possess weak acid properties; the other yellow, and soluble in water. Carthamin, $C_{14}H_{16}O_7$, exists to the amount of from 0·3 to 0·6 per cent. only in the safflower, while the safflower-yellow, to which Malin gives the formula $C_{24}H_{30}O_{15}$, is present to the amount of from 24 to 30 per cent. It is the former which renders safflower useful as a dye-stuff. These flowers are sometimes fraudulently mixed with saffron, which they resemble in color, but from which they may be distinguished by their tubular form, and the yellowish style and filaments which they enclose. In large doses

carthamus is said to be laxative; and, administered in warm infusion, diaphoretic. It is used in domestic practice, as a substitute for saffron, in *measles*, *scarlatina*, and other *exanthematous diseases*, to promote the eruption. An infusion, two drachms to a pint of boiling water, is usually employed *pro re nata*.

CARUBA DI GUIDEN. Under this name are largely used, for the relief of *asthma*, certain gall-like bodies, formed on various species of Pistacia (especially *P. terebinthina*), as the result of the stings of an hemipterous insect. According to Ignaz Hoffmann, they are used by smoking and fumigation. For this purpose they are coarsely pulverized and burnt in the bowl of a pipe, or in a dish, with some arrangement by which the fumes may be inhaled. Preparations should be made beforehand, so that the smoke may be inhaled at the commencement of the attack. They appear to act by exciting free secretion, probably through the turpentine with which they are saturated. They are also said to be very useful in *chronic bronchitis*. (*Schmidt's Jahrb.*, Bd. clii.)

CARVACROL. $C_{10}H_{13}OH$. A phenol-like body existing in the essential oils of species of *Origanum*. It forms a thick oil which does not solidify at 25° C., boils at from 233°–235° C., and possesses powerful antiseptic properties.

CARVACROL IODIDE. *Iodocrol*, $C_{10}H_{13}OI$, is a bulky, grayish-yellow or buff-colored amorphous powder having a faint aromatic odor. It is insoluble in water, slightly so in alcohol, soluble in ether, chloroform, benzin, carbon disulphide, volatile and fixed oils. From its solution in ether and chloroform it is precipitated on the addition of alcohol, becoming paler in color. This purified product does not show signs of shrinkage until above 170° C., and at 200° C. becomes tarry and black. It is alleged that it combines the antiseptic properties of carvacrol with those of iodine, and possesses the advantage over iodoform in being odorless or nearly so, and in being five times as bulky.

A. H. Cohn finds it to be actively antiseptic, and has used it successfully in almost all surgical dressings: *eczema*, *pruritus*, *chancres*, *chancroids*.

CARYA. *Hickory.* (Nat. ord. Juglandaceæ.) Several species of the genus Carya, of Nuttall, separated by that botanist from the *Juglans* of Linnæus, grow in the United States, of which *C. olivæformis*, Nutt., bears the *pecan-nut* of the Southwest, *C. alba*, Nutt., the fruit so well known by the name of *shell-bark*, derived probably from the ragged state of the bark of the stem, *C. sulcata*, Nutt., another variety of shell-bark, and *C. tomentosa*, Nutt., the common thick-shelled hickory-nut. Other indigenous species are *C. amara*, Nutt., *C. porcina*, Nutt., and *C. microcarpa*, Nutt. The leaves of most if not all of these trees are somewhat aromatic and astringent, and the bark astringent and bitter. In the bark of *C. tomentosa* Mr. F. R. Smith found a crystalline principle, *caryin*, which he believes to be identical with *quercitrin*. Mr. Caffinbury, of Michigan, commends the inner bark of the hickory in *dyspepsia* and in *intermittent fever*. (*Proc. A. P. A.*, 1859, 249.) Sargent and Britton and Brown restore the generic name of *Hicoria* of Rafinesque for this genus, and refer *Carya olivæformis*, Nutt., to *Hicoria pecan* (Marsh), Britt.; *C alba*, Nutt., to *H. ovata* (Mill.), Britt.; *C. tomentosa*, Nutt., to *H. alba* (L.), Britt.; *C. sulcata*, Nutt., to *H. laciniosa* (Michx. f.), Sarg.; *C. amara*, Nutt., to *H. minima* (Marsh), Britt.

CASCARA AMARGA. For an elaborate discussion of the microscopic and chemical characters of *Honduras bark* of commerce and its alkaloid *picramnine*, by Dr. F. A. Thompson, see *A. J. P.*, June, 1884.

CASEARIA ESCULENTA. This Indian plant is said to be a valuable remedy in *hepatic torpor*, and to contain an organic acid allied to cathartic acid. (*P. J. Tr.*, xx.)

CASEIN. This substance is one of the important constituents of milk and cheese, and is alluded to under *Lac*. It has been proposed by Mr. Seger as an emulsifying agent in pharmacy. One gallon of milk is treated with two and a half fluidounces of water of ammonia for twenty-four hours, and, after removing the saponaceous matter from the surface of the mixture, the serum is precipitated with acetic acid. The magma of casein, strongly pressed, is treated with sodium bicarbonate, and with a sufficient quantity of sugar to make the dried product contain one-tenth of its weight of casein. The powdered substance dissolves easily in water, and, mixed with its weight of gum, may be used for almost all of the emulsions. Resinous matters and balsams previously dissolved in alcohol, essences, and oils, may be mixed with it in the bottle itself without using the mortar. The only defect in this casein saccharate is its slight odor. (*L'Union Pharm.*, May, 1887.)

CASIMIROA EDULIS. *Zapote blanco. Cochilsapote. White Sapota.* This is a large tree belonging to the family of Rutaceæ, a native of Mexico, whose leaves are employed in *diarrhœa*, and whose seeds are said to be narcotic.

CASSIA MARYLANDICA. L. *Séné Américain*, Fr. *Amerikanische Senna*, G. (Nat. ord. Leguminosæ.) *American senna* is an indigenous perennial plant of vigorous growth, sending up annually numerous round, erect, nearly smooth stems, which are usually simple, and rise from three to six feet in height. The leaves are alternate, and composed of from eight to ten pairs of oblong-lanceolate, smooth, mucronate leaflets, green on their upper surface, pale beneath, and connected by short petioles with the common footstalk, which is compressed, channelled above, and furnished near its base with an ovate, stipitate gland. The flowers, which are of a beautiful golden-yellow color, grow in short axillary racemes at the upper part of the stem. The calyx is composed of five oval, obtuse, unequal yellow sepals; the corolla of the same number of spatulate, concave petals, of which three are ascending, and two descending and larger than the others. The stamens are ten, with yellow filaments and brown anthers, which open by a terminal pore. The three upper stamens bear short abortive anthers; the three lowermost are long, curved, and tapering into a beak. The ovary bears an erect style terminating in a hairy stigma. The fruit is a pendulous legume, from two to four inches long, linear, curved, swelling at the seeds, somewhat hairy, and of a blackish color. The *American senna*, or *wild senna*, is very common in all parts of the United States south of New York, and grows as far northward as New England. It prefers a low, moist, rich soil, in the vicinity of water, and, though frequently found in dryer and more elevated places, is most abundant and luxuriant in the flat ground on the borders of rivers and

ponds. The leaves, which should be collected in August or the beginning of September, are sometimes brought into the market, compressed into oblong cakes, like those prepared by the Shakers from most herbaceous medicinal plants. The leaflets are from an inch and a half to two inches long, from one-quarter to half an inch in breadth, thin, pliable, and of a pale green color. They have a feeble odor, and a nauseous taste, somewhat analogous to that of senna. Water and alcohol extract their virtues. Hermann J. M. Schroeter (*A. J. P.*, 1888, 231) found in them a yellow coloring matter identical with *chrysophanic acid;* also an active principle corresponding in all respects with *cathartic acid.* For earlier analysis by Martin, see *A. J. P.*, i. 22. American senna is an efficient and safe cathartic, acting like senna but more feebly.

Cassia nictitans, L., was investigated by Gallaher (*A. J. P.*, 1888, 280), who failed to find any glucoside or alkaloid. The amount of volatile oil found was very small, and cathartic acid could not be prepared from it, although the powder produced griping. The leaves of *Cassia alata*, L., are recommended by Conillebault in *ringworm;* they are moistened and the parts affected rubbed with them. (*A. J. P.*, 1887, 266.)

Under the names of *Cheshmat*, *Chashmizok*, *Schischen*, the seeds of C. *absus*, L., are said to be used in India and Africa in the treatment of inflammations of the eye, either in the form of a fine powder or an infusion to which several medicinal substances are added.

CASTANEA PUMILA. (L.) Mill. *Chinquapin.* (Nat ord. Fagaceæ.) The chinquapin is a shrub or small tree, which in the Middle States rarely much exceeds seven or eight feet in height, but in the Carolinas, Georgia, and Louisiana sometimes attains an elevation of thirty or forty feet, with a diameter of trunk equal to twelve or fifteen inches. The leaves are oblong, acute, mucronately serrate, and distinguished from those of the chestnut, which belongs to the same genus, by their whitish and downy under surface. The staminate flowers are grouped upon axillary peduncles, three or four inches long; the fertile aments are similarly disposed, but less conspicuous. The fruit is spherical, covered with short prickles, and incloses a brown nut, which is sweet and edible, but differs from the chestnut in being much smaller, and convex on both sides. The tree extends from the banks of the Delaware southward to the Gulf of Mexico and southwestward to the Mississippi. The bark is the part used. It is astringent and tonic, and has been employed in *intermittents.* For analysis of chinquapins and economic consideration, see *A. J. P.*, 1895, 453.

CASTELLA NICHOLSONI. Hook. (Nat. ord. Simarubeæ.) This plant is reputed to have antiseptic properties, probably due to a resinous principle discovered by J. L. Putegnat and named by him *amargosin.* (See *N. R.*, April, 1883.)

CASTOREUM. *Castor. Castoréum*, Fr. *Bibergeil*, G. *Castoro*, It. *Castoreo*, Sp. In the beaver, *Castor fiber*, between the anus and external genitals of both sexes, are two pairs of membranous follicles, of which the lower and larger are pear-shaped, and contain an oily, viscid, highly odorous substance, secreted by glands which lie externally to the sac. After death, the follicles containing castor are removed, and dried either by smoke or in the sun.

This drug is derived either from the northern and northwestern parts of America, or from Russia, and is distinguished, according to its source, into the Canadian or American and Russian castor. It is supposed by some that the American and Russian beavers are distinct species, the former being a building, the latter a burrowing animal; and additional ground for the supposition is afforded by the fact that the products of the two differ considerably. Of the Russian but a very small portion reaches this country; large quantities were formerly collected in the northwestern regions of British America.

Castor comes to us in the form of solid unctuous masses, contained in sacs about two inches in length, larger at one end than at the other, much flattened and wrinkled, of a brown or blackish color externally, and united in pairs by the excretory ducts which connect them in the living animal. In each pair one sac is generally larger than the other. They are divided internally into numerous cells, containing the castor, which, when the sacs are cut or torn open, is exhibited of a brown or reddish-brown color, intermingled more or less with the whitish membrane forming the cells. Those brought from Russia are larger, fuller, heavier, and less tenacious than the American; and their contents, which are of a rusty or liver color, have a stronger taste and smell, and are considered more valuable as a medicine. A variety of Russian castor, described by Pereira under the name of *chalky Russian castor*, is in smaller and rounder sacs than the American, has a peculiar empyreumatic odor very different from that of the other varieties, breaks like starch under the teeth, and is characterized by effervescing with dilute hydrochloric acid. Müller found 40·646 per cent. of calcium carbonate. According to M. Kohli, Canadian castor, treated with distilled water and ammonia, affords an orange precipitate, while the matter thrown down from the Russian under similar treatment is white.

Properties. Good castor has a strong, fetid, peculiar odor; a bitter, acrid, and nauseous taste; and a color more or less tinged with red. It is of a softer or harder consistence according as it is more or less thoroughly dried. When perfectly desiccated, though still somewhat unctuous, it is hard, brittle, and of a resinous fracture. Its chemical constituents, according to Brandes, are volatile oil; a resinous matter; albumen; a substance resembling *osmazome;* mucus; calcium urate, carbonate, benzoate, phosphate, and sulphate; sodium acetate and chloride; potassium chloride, sulphate, and benzoate; ammonium carbonate; membranous matter; and a peculiar proximate principle discovered by M. Bizio, an Italian chemist, and called by him *castorin.* This principle crystallizes in long, diaphanous, fasciculated prisms, has the smell of castor, and a copperish taste. It is insoluble in cold water and cold alcohol; but is dissolved in 100 parts of the latter liquid at the boiling temperature, and by the essential oils. It possesses neither alkaline nor acid properties, and is considered as belonging to the cholesterin group of bodies. It may be obtained by treating castor, minutely divided, with six times its weight of boiling alcohol, filtering the liquor while hot, and allowing it to cool. The *castorin* is slowly deposited, and may be purified by means of cold alcohol. M. Valenciennes, who could not obtain the crystals white and pure by simple treatment with alcohol, suc-

ceeded by first boiling a mixture of equal parts of castor and hydrated lime with water, and acting upon the residue, separated and dried, with boiling alcohol of the sp. gr. 0·823. Canadian castor is said to yield 1·98 per cent., and Russian castor 4·60 per cent., of castorin. This, together with the volatile oil and the peculiar resin, are said to constitute the medicinal principles. (Pennetier, *Matières Premières Organiques*, 783.) The *volatile oil* may be obtained by repeated distillation with the same portion of water. It is pale yellow, and has the smell and taste of castor.

F. Wöhler ascertained the existence of salicin and of carbolic acid in a specimen of castor; Dr. Pereira detected *salicylic aldehyde* (*oil of Spiræa ulmaria*) in castor, and concluded that the oil of castor had been converted into that principle. (*P. J. Tr.*, xi. 200.) The salicin of the castor, however, probably proceeds from the willow and poplar on which the beaver feeds.

Alcohol and ether extract the virtues of castor. An infusion made with boiling water has its sensible properties in a slight degree; but the odorous principle of the drug is dissipated by decoction. The virtues of castor are impaired by age. Warmth, and especially moisture, promote its decomposition. In a dry cool place it may be kept for a long time without material deterioration. When quite black, with little taste or smell, it is unfit for use. The castor follicles are sometimes partly deprived of the castor, and its place supplied with sawdust. A factitious preparation has been sold, consisting of a mixture of various drugs, scented with genuine castor, intermingled with membrane, and stuffed into the scrotum of a goat. The fraud may be detected by the comparatively feeble odor, the absence of other characteristic sensible properties, and the want of the smaller follicles containing fatty matter, often attached to the bags of castor.

Medical Properties and Uses. Castor is moderately stimulant and antispasmodic. It has also enjoyed a high reputation as an emmenagogue. It was employed by the ancients. Pliny and Dioscorides speak of it as useful in *hysteria* and *amenorrhœa*. In Europe, especially on the continent, it is still prescribed in low forms of *fever* attended with nervous symptoms, and in spasmodic diseases, such as *hysteria* and *epilepsy*. Dose, from ten to thirty grains (0·65–1·95 Gm.), in capsules or emulsion. *Tincture of Castor*, made by macerating one ounce of bruised castor for seven days in one imperial pint of alcohol, was formerly official in the British Pharmocopœia.

A substance allied to castor is the secretion of the anal glands, used for the purpose of defence by the *Mephitis mephitica*, or *common skunk* of North America. According to T. B. Aldrich, this is a neutral, golden-colored liquid, having an extremely penetrating and not altogether agreeable odor, containing mercaptan, allyl-sulphide, and traces of butyl-mercaptan. (*Chem. and Drug.*, 1897.)

CATALPA BIGNONIOIDES. Walt. *Bignonia Catalpa.* Linn. *Catalpa Catalpa.* (L.) Karst. *Catalpa-tree*, or *Catawba-tree.* This is a beautiful indigenous flowering tree, of the nat. ord. Bignoniaceæ, the seeds of which have been employed in *asthma*. Eugene O. Rau obtained from them tannin and a bitter crystalline principle. (*A. J. P.*, xlii. 204.) F. K. Brown obtained from the seeds resin, fixed oil, tannin, sugar, and two crystalline bodies, their exact nature not being determined. (*A. J. P.*, 1887, 230.) I. Schneck states that large doses cause nausea, vomiting, and slow, weak, intermittent pulse. He gave two drachms of tincture (℥i to Oi) every one to three hours.

CATAPLASMATA. *Cataplasms. Poultices*, E. *Cataplasmes*, Fr. *Umschläge, Breiumschläge*, G. Cataplasms, or *poultices*, are moist substances intended for external application, of such a consistence as to accommodate themselves accurately to the surface to which they are applied, without being so liquid as to spread over the neighboring parts, or so tenacious as to adhere firmly to the skin. As they are in this country seldom made by the apothecary, they were not deemed by the compilers of the U. S. Pharmacopœia proper objects for official direction. For formulas for cataplasms, see pp. 337–339, 17th edition *U. S. Dispensatory*.

CATARIA. *Nepeta Cataria.* L. *Catnep* or *Catmint* (*Cataire*, Fr.; *Katzenmünze*, G.; *Cattara*, It.; *Gatera*, Sp.) is a perennial labiate plant, with a quadrangular, branching, somewhat hoary stem, from one to three feet high, and furnished with opposite petiolate, cordate, dentate, pubescent leaves, which are green above and whitish on their under surface. The flowers are whitish or slightly purple, are arranged in whorled spikes, and appear in July and August. The plant is abundant in the United States, but is supposed to have been introduced from Europe. The whole herb is used: it has a strong, peculiar, rather disagreeable odor, and a pungent, aromatic, bitterish, camphorous taste. The active constituents are volatile oil, and tannin of the kind which produces a greenish color with the salts of iron. In its operation upon the system, catnep is tonic and excitant, bearing considerable resemblance to the mints. It has had the reputation also of being antispasmodic and emmenagogue. Cats are very fond of it, and it has been asserted to act as an aphrodisiac in these animals. Its infusion—dose, two drachms (7·77 Gm.)—is employed as a domestic remedy in *amenorrhœa*, *chlorosis*, *hysteria*, and the flatulent *colic* of infants.

CATHA EDULIS. Under various Arabic names, such as *Kât*, *Khât*, *Chaat*, *Kus es Salahin*, *Tchaad*, *Tschut*, *Tohat*, *Tohai*, *Gât*, the leaves of the *Catha Edulis* (*Abyssinian* or *African tea*) are very largely used as a stimulant in North Africa, the plant in some localities being extensively cultivated. According to Collin, from 1400 to 1500 camel-loads are sold in a year at the centre of commerce in Aden. The plant is a shrub, reaching the height of three or four yards, with thin coriaceous leaves whose margin is bluntly serrate. The rounded, grayish-green twigs are, for commercial purposes, dried with the leaves and tied together in bundles containing about forty twigs, from twelve to fourteen inches in length and three to four inches in diameter. Sometimes the bundles are much smaller. The leaves are chewed both green and fresh, and are in some places made into a tea. Their taste is said to resemble that of coca, and the inebriation which they produce in the Arabs is described as similar to that caused by coca in the South American natives.

So far as known *Catha* is not used as a medicine in Africa, but has been employed to some extent as a stimulant in Europe in *neurasthenia*, *migraine*, and allied conditions. It has been studied by various European chemists. Bernon concluded that there is no alkaloid in it. Flückiger and Gerock isolated a volatile liquid, which they believe to

be an alkaloid, and to which they gave the name of *katine*. Mosso (*Med. Bull.*, vol. xiii. No. 8) also isolated an alkaloid, *celastrine*, which he believed to resemble in its physiological action cocaine, though more energetic. In 1897 T. Shennan (*Royal Coll. Phys. Lab. Rep.*, vi. 1897) obtained evidences of the existence of a non-volatile alkaloid in the leaves, different from caffeine. He found that catha, both in cold-blooded and warm-blooded animals, produces drowsiness, followed by excessive reflex activity, and, if the dose has been large enough, violent tetanus. Catha evidently belongs among the domestic stimulants, such as tea and coffee, and probably contains an active alkaloid belonging to the caffeine group.

CATRAMINE. A terebinthinate, essential oil, recommended by Vincenzo Gauthier (*Gazz. degli Ospitali*, Feb. 1892) as a stimulant expectorant and diuretic, resembling the oil of turpentine.

CAYAPONIA GLOBOSA. *Silva Manso.* This is a cucurbitaceous plant of Brazil, from which Prof. Gubler has extracted the alkaloid *Cayaponine*, said to purge without griping. Dose, one grain (0·06 Gm.). (*Rép. de Pharm.*, 1879, 193.)

CEANOTHUS AMERICANUS. L. *New Jersey Tea. Red-root Céanothe*, Fr. *Seckelblumen-wurzel*, G. A small indigenous shrub, of the nat. ord. Rhamnaceæ, growing throughout the United States. The root is astringent, and imparts a red color to water. H. K. Bowman found in it 9·21 per cent. of tannin. (*A. J. P.*, 1869, 195.) F. C. Gerlach has again examined the root. (*A. J. P.*, 1891, 332.) He finds 6·48 per cent. of tannin and 0·52 per cent. of an alkaloid to which he gives the name *ceanothine*. J. H. M. Clinch has found in the leaves a resin and a volatile oil. (*A. J. P.*, xiv., 1884.) J. A. Buckner (*A. J. P.*, 1891, 428) found 9·45 per cent. of tannin in the leaves. It is said to be useful in *syphilis*. Schoepf states that it is purgative. The leaves were used during the Revolutionary War as a substitute for tea.

CEARIN. An ointment vehicle capable of taking up a large proportion of water. Issleib recommends a mixture of one part of carnauba wax and three parts of paraffin (bleached by exposure to sunlight only); this is fused and mixed with four times its weight of liquid petrolatum and stirred until cold.

CEBUR or TAGULAWAY BALSAM is prepared in the Philippine Islands by boiling the root and twigs of *Parameria vulneraria*, Radl (nat. ord. Apocynaceæ), in cocoa-nut oil, so as to form a yellowish-white, oily liquid, which is used with asserted excellent results for *skin diseases* and *wounds*. (*Archiv. de Pharm.*, Nov. 1885.)

CEDAR GUM. This, the product from *Cedrela Australis*, F. Muell., or *Red Cedar* of Queensland (nat. ord. Meliaceæ), is a very pale yellow gum, occurring in tears about an inch long, feeling leathery between the teeth, swelling and, finally, almost dissolving in water. It contains about 68 per cent. of arabin, and 6 per cent. of metarabin, but no resin. (*P. J. Tr.*, vol. xx., 1890.)

CEDRON. The seeds of the *Simaba cedron*, Planch., a tree growing in Colombia and Central America, belonging to the Simarubaceæ. For description of the tree and its botanical and medicinal history, see 16th ed. *U. S. D.* The fruit is a large solitary drupe, containing a single seed. A specimen of the dried fruit, sent to George B. Wood from Cartago, in Costa Rica, by Dr. Guier, formerly of Philadelphia, was light, of a yellowish-ash color, flattish-ovate, with one edge convex and the other nearly straight, the convex outline terminating at each end in an obtuse point, of which that at the apex was most prominent. It was about two inches long and sixteen lines in its greatest breadth. Within, the seed was loose and movable. Cedron seed is about an inch and a half long, ten lines broad, and half an inch thick, convex on one side, flat or slightly concave on the other, and presenting an oval scar near one extremity of the flat surface. It is often yellowish, hard and compact, but readily cut with a knife, is inodorous, but of a pure and intensely bitter taste, not unlike that of quassia. It yields its virtues to water and alcohol. M. Lowry obtained from it a crystalline substance, intensely bitter, freely soluble in boiling water, and neutral to test-paper, which he supposes to be the active principle, and named *cedrin*. He first exhausted the cedron with ether, then treated it with alcohol, and crystallized from the tincture. (*Journ. de Pharm.*, xix. 335.) Cedrin is now an article of commerce in form of yellowish transparent crystals, easily soluble in water, less so in alcohol.

This medicine has long had great reputation in Central America as a remedy for the *bite of serpents*, being mentioned in the *History of the Buccaneers*, published in 1699, as useful for this purpose. It has also been alleged that cedron-seed will cure *hydrophobia*, and S. S. Purple, of New York, affirms it to have valuable antiperiodic properties when given in doses of from ten to thirty grains (0·647–1·94 Gm.) every four hours. In very large dose, Purple found it to gripe and purge. (*N. Y. Med. Journ.*, N. S., xiii.)

CELASTRUS. Various species of the Celastraceæ have medicinal properties. In the East Indies the oil obtained from the seeds of the *Celastrus paniculata*, Willd., is used as a powerful stimulant and diaphoretic in *rheumatism*, *gout*, and various *fevers*. The oil is said to be deep reddish yellow, and to become thick and honey-like on keeping. It is sometimes known as *oleum nigrum*. In Abyssinia, according to Prof. Dragendorff, the leaves of the *C. obscurus*, A. Rich (now *C. serratus*, Hochst.), are used as an antiperiodic under the name of *Add-add*. Dragendorff found in them tannic acid, a volatile oil, and a bitter principle, *celastrine*. (*A. J. P.*, xxvi.) In North America the bark of the *Celastrus scandens*, L. (*Climbing staff-tree*, *False bittersweet*, *Fever-twig*), has been used in chronic affections of the *liver* and in *secondary syphilis;* and is said to be emetic, diaphoretic, and alterative. C. H. Bernhard found in the bark acid and neutral resin, starch, glucose, gum, a caoutchouc-like body, coloring matter, and volatile oil. It yields its virtues best to alcohol of 80 per cent. (*A. J. P.*, 1882, 1.) Prof. Wayne states that he has isolated from *C. scandens* white minute crystals, to which he gave the name of *celastrine*.

CELLULOID. *Zylonite.* This material, which has been manufactured into so many useful forms, furnishes an excellent substitute for ivory, tortoise-shell, amber, and vulcanite. It is a nitro-cellulose, which is made capable of moulding into any desired form by the admixture of a small amount of camphor. At the temperature at which the camphor melts, it acts as a solvent for the nitro-cellulose and forms a uniform plastic mass with it. This mass may be used directly in the manufacture of

various articles, or it may be admixed with mineral coloring matters so as to imitate the various natural stones. The stratified appearance of ivory and the mottled appearance of tortoise-shell and amber are obtained by passing between heated rolls plain and colored or clouded celluloid in alternating layers. The material is combustible when ignited, and in thin pieces burns rapidly with a bright light.

CELTIS RETICULOSA. Miq. (Now *C. cinnamomea.* Lindl.) Prof. W. R. Dunstan has isolated *skatole*, the substance to which the odor of the human fæces is due, from the wood of this East Indian tree. (*P. J. Tr.*, June, 1889.)

CENTAUREA BENEDICTA. L. *Blessed Thistle. Carduus Benedictus. Cnicus Benedictus. Herba Cardui Benedicti*, P. G. *Chardon bénit*, Fr. *Benedicten Distel*, G. This is an annual herbaceous plant of the nat. ord. Compositæ, common in Europe and the United States. For description, see 16th ed. *U. S. D.* The period of flowering is June, when its medicinal virtues are in greatest perfection. The leaves were formerly official. They should be gathered when the plant is in flower, quickly dried, and kept in a dry place. The herb has a feeble, unpleasant odor and an intensely bitter taste, more disagreeable in the fresh than in the dried plant. Water and alcohol extract its virtues. The infusion with cold water is a grateful bitter; the decoction is nauseous, and offensive to the stomach. The active constituents are volatile oil and *cnicin.* This is crystallizable, inodorous, very bitter, neutral, scarcely soluble in cold water, more soluble in boiling water, and soluble in all proportions in alcohol. Its formula is $C_{42}H_{56}O_{15}$, and it is analogous to salicin in composition. In the dose of four or five grains it is said often to vomit, whilst eight grains, given in divided doses, is useful in *intermittent fevers.* (*Ann. de Thérap.*, 1843, 206.) In cold infusion this drug is tonic; when taken in hot infusion in large quantities it is diaphoretic, or in larger quantities, emetic. Tonic dose of the infusion (ounce to a pint), two fluidounces (60 C.c.); of the powder, from half a drachm to one drachm (1·94–3·88 Gm.).

Carduus Marianus, L. (now *Silybum Marianum*, Gaertn.), was of old used for the same purpose as the *C. benedictus.* Rademacher attributed great value to the seeds in *hemorrhages*, particularly when connected with diseased liver or spleen. Dr. Lobach found the decoction (two ounces to the pint of water), in doses of a tablespoonful (15 C.c.) every hour, useful in *amenorrhœa* and *menorrhagia.* (*Am. Journ. Med. Sci.*, April, 1859.)

CENTAURY. *Common European Centaury. Centaurium.* The *Erythræa Centaurium* (Pers., also (L.) Pers.), *Gentiana Centaurium* (L.), *Chironia Centaurium* (Schmidt), (Willd. *Sp. Plant.* i. 1068), *Herba Centaurii* (P. G.), is a small, annual herbaceous plant which grows wild in most parts of Europe. It rises about a foot in height, with a branching stem, which divides above into a dichotomous panicle, and bears opposite, sessile, ovate-lanceolate, smooth, and obtusely pointed leaves. The flowers are of a rose color, sessile in the axils of the stems, with their calyx about half as long as the tube of the corolla.

The herb, though without odor, has a strong bitter taste, which it imparts to water and alcohol. The flowering summits were formerly official in the Edinburgh Pharmacopœia. The fresh herb yields by distillation an odorous watery product, of pungent taste (*Geiger*, ii. 482), in which M. Méhu has found valerianic acid, also a peculiar colorless, crystallizable, non-nitrogenous substance, *erythrocentaurin* ($C_{27}H_{24}O_8$), which he obtained by exhausting the tops with water, evaporating a portion of the water, allowing the residue to stand, separating the precipitated matter or apotheme, adding alcohol to the remaining liquid, which now deposited a bitter substance, and, after the separation of this by decantation, evaporating the liquid to the consistence of syrup, and treating the residue with ether. The ethereal solution, upon evaporation, yielded the erythrocentaurin in crystals. These are needle-shaped, fusing at 136° C., and crystallizing easily on cooling again. They are strongly reddened by exposure to solar light, and reacquire their colorless character upon being again dissolved and crystallized, or by mere heating to 130° C. They are almost insoluble in cold water, more readily soluble in boiling water, alcohol, ether, and chloroform. Carbon disulphide, benzol, volatile and fatty oils dissolve them easily. J. F. Huneker believes that erythrocentaurin exists also in American centaury. (See *Sabbatia.*) Besides these principles, Méhu found also in centaury a *wax-like substance* and saline matter. (*Journ. de Pharm.*, xliii. 38.) Leuderich assigns to *erythrocentaurin* the formula $C_9H_{14}O_5$, and states that in its decomposition a dextro-rotatory carbohydrate is produced. (*A. J. P.*, 1892, 311.) The common centaury of Europe has tonic properties very closely resembling those of gentian. It is employed in *dyspeptic complaints.* It was one of the ingredients of the *Portland powder.* The dose of the powder is from thirty grains to a drachm (1·94–3·88 Gm.).

A species of Erythræa (*E. Chilensis*) is employed to a considerable extent in Chili as a mild tonic. For details, see *Journal de Pharmacie* (3e sér., xxv. 434). *E. acaulis*, which grows in great abundance in the territory of French Algiers bordering on the Sahara, yields a root which, under the name of *rejagnou*, is much employed by the natives for dyeing yellow. (*Ibid.*, 4e sér., v. 87.)

CEPHALANTHUS OCCIDENTALIS. L. *Button-bush. Buttonwood. Crane-willow. Swamp Dogwood.* (Nat. ord. Rubiaceæ.) A common indigenous shrub which grows in moist places, as along streams or on the borders of swamps. Its bark is bitter, is said to be laxative as well as tonic, and has been given in periodical fevers, in decoction or infusion. E. M. Hattan found in it a crystallizable fluorescent acid, a bitter uncrystallizable principle, a principle resembling saponin, tannin, two resins, fatty matter, gum, glucose, and starch. (*A. J. P.*, xlvi. 314.) According to Claasen (*Pharmaceut. Rundschau*, Bd. vii., 1889), the fluorescent acid of Hattan is composed of two substances, *Cephalin* and *Cephaletin.* Carl Mohrberg has separated from the bark a substance which he knows as *Cephalanthin;* and also a toxic saponin-like principle which, like its allied poisons, has the power of dissolving the blood-corpuscles. Cephalanthin he finds to be a distinct poison to both cold- and warm-blooded animals, causing destruction of the blood-corpuscles (with conversion of oxyhæmoglobin into methæmoglobin), violent vomiting, convulsions, and paralysis. (See *Kobert's Arbeiten*, viii., 1892.)

CERATOPETALUM. The New South Wales species of this genus, of the nat. ord. Saxifragaceæ,

yield considerable quantities of a kino-like gum. (See *P. J. Tr.*, xxi. 742.)

CERCIS CANADENSIS. L. *Judas Tree. Red-bud.* The bark of this beautiful leguminous tree, indigenous and well known throughout the Eastern United States on account of its brilliant red-purple flowers, which appear before the leaves, has been highly recommended by Dr. Wm. R. Smith as a mild but very active astringent in the treatment of *chronic diarrhœa* and *dysentery*. Dose of the fluid extract, from half to one fluidrachm (1·85–3·7 C.c.).

CERESIN. Under this name there has been introduced into commerce, as a substitute for wax, a substance which closely resembles white wax, but which is a natural mineral product. It is found most abundantly in Galicia, on the slopes of the Carpathian Mountains, and also on the Wallachian side of the range, under the name of *ozokerite* (earth-wax), but occurs in smaller deposits on the Caspian under the name *neft-gil*. A valuable deposit has also been discovered in Southern Utah. It consists of a mixture of solid paraffin with some oxygenated bodies present. The crude ozokerite is melted to allow earthy impurities to settle out, is treated with sulphuric acid and alkali, as in the treatment of paraffin, and is clarified by bone-black, or, better, the black from the manufacture of yellow prussiate of potash. The refined ozokerite or ceresin melts between 61° and 78° C., is quite odorless and colorless, and has the appearance of beeswax. It may be distinguished from the latter by its lower specific gravity (0·753 at 98° C. against 0·822) and its absolute resistance to alcoholic potash, no trace of saponifiable matter being present. The production of Galician ozokerite in 1886 amounted to 13,925 tons, but had fallen in 1896 to 7925 tons. The production of Utah ozokerite in 1890 amounted to 350,000 pounds. The Galician product is worked chiefly in Vienna and in London, where ozokerite candles are manufactured. (See *A. J. P.*, xlv. 11.) In this country ceresin bottles have been used for hydrofluoric acid, and seem to be superior to the common gutta-percha bottles.

CEREVISIÆ FERMENTUM. *Beer Yeast.* The ferment obtained in brewing beer, and produced by *Saccharomyces* (*Torula*, Turpin) *cerevisiæ*, Meyen, was dismissed from the U. S. Pharmacopœia in 1880, from the British in 1898. Two well-marked varieties of the *Saccharomyces cerevisiæ* have been recognized. The one is the most active at the ordinary temperature (16°–20° C.), and carries through its fermentative work in from three to four days; the other works at a lower temperature (6°–8° C.), and the fermentation is much slower. The first placed in a saccharine liquid is carried by the carbon dioxide which it liberates to the surface of the liquid, where it continues its activity; it is, therefore, known as a surface or top yeast. The second, on the contrary, is not carried up, and rests during its entire activity on the bottom of the fermenting vessel, and is hence called a bottom yeast. Two quite distinct methods of beer-brewing are practised, depending upon the use of the one or the other of these varieties of yeast. For fuller information as to the nature of yeast and its conditions of culture and activity, see Sadtler's *Industrial Organic Chemistry*, Philadelphia, 2d ed., 1895, 184 *et seq.*)

Yeast is flocculent, frothy, somewhat viscid, semi-fluid, of a dirty yellowish color, a sour vinous odor, and a bitter taste. Exposed to a moderate heat it loses its liquid portion, becomes dry, hard, and brittle, and may in this state be preserved for a long time, though with the loss of much of its peculiar power. *Yeast cakes* are made by putting yeast into sacks, washing it with water, then submitting it to pressure, and ultimately drying it. (*Ibid.*, 225.)

Yeast is insoluble in alcohol or water. Its ultimate composition, according to Schlossberger (*Ann. Chem. und Pharm.*, 51, 199), is carbon 49·9 per cent., hydrogen 6·6 per cent., nitrogen 12·1 per cent., and oxygen 31·4 per cent. Its proximate constituents are albuminoids, celullose, fats, and resinous substances.

The chief function of yeast is the production of the vinous fermentation, in which are produced alcohol and carbonic acid, and various other substances in smaller or larger proportions. Pasteur has shown that while from 94 to 95 per cent. of the sugar decomposes into ethyl alcohol and carbon dioxide, the other 5 or 6 per cent. decomposes by secondary reactions, yielding *glycerin* from 2·5 to 3·6 per cent. and *succinic acid* from 0·4 to 0·7 per cent. The higher homologues of ethyl alcohol are also produced in small amount, forming the fusel oil or the raw spirit.

The activity of yeast is due to the presence of a microscopic fungus, first discovered in it by Leuwenhoek in 1680. As originally announced by Thénard in 1803, this yeast plant is the cause of the alcoholic fermentation. It consists of numerous cells, irregular, roundish, or cylindrical in shape, separate, jointed into rows, or budding one from the other. It is most probable that the yeast plant is the mycelium, or early vegetative stage, of more than one species of mucor or mould; and some authorities recognize various species of the yeast fungus. The name of *Torula*, or *Torula cerevisiæ*, was first given to the yeast plant, which was subsequently called *Mycoderma vini;* Dr. M. Reess, in his elaborate work (*Alkoholsgährungspilze*, Leipsic, 1870), made a distinct genus of it, *Saccharomyces*, including many species.

There have been three theories in regard to fermentation: 1st, that it is a chemical process; 2d, that it is of galvanic origin; 3d, that it is the result of the vital actions of the yeast plant. The chemical theory founded by Trommsdorff and Meissner was advocated by Liebig, but, chiefly owing to the labors of Pasteur, the vital theory is now universally accepted.

Yeast has been highly commended as a stimulant remedy in *typhoid*, *hectic*, and other similar fevers, but is at present very rarely used. In some of these cases it has been given with great asserted advantage in doses of a pint (473·1 C.c.) a day. It still continues to be employed to a considerable extent as a remedy against successive *eruptions of boils*, in doses of an ounce (29·5 C.c.) three times a day. Locally applied it is probably stimulant, although it may be the products of fermentation rather than the yeast which give the peculiar value to the "yeast poultice."

CERIUM BROMIDE. Ce_2Br_6. This salt is prepared by Mr. Charles Bullock by calcining the oxalate in a porcelain capsule until it becomes converted into the yellowish-brown sesquioxide, dissolving this in hydrochloric acid, precipitating with sodium carbonate, and dissolving in hydrobromic acid, then evaporating at a low tempera-

ture to dryness. The salt is of a light chocolate color, and of a very styptic sweetish taste, soluble in 95 per cent. alcohol, partially soluble in water. (*A. J. P.*, xliii. 345.)

CHAMÆLIRIUM LUTEUM. A. Gray, also (L.) A. Gray. *C. Carolinianum.* Willd. *Veratrum luteum.* L. *Helonias lutea.* Ker-Gawl in *Bot. Mag. Helonias Dioica.* Pursh. *Starwort. False Unicorn Root. Devil's Bit. Blazing Star.* This plant is indigenous to the United States. The rhizome is the part employed in medicine. Dr. F. V. Greene obtained a bitter principle, *chamælirin*, from it in 1878. He states that it is a cardiac poison. *Helonin* is a term used by the eclectics to define the alcoholic extract found in commerce. Chamælirium, or starwort, is said to be diuretic, tonic, and anthelmintic. It is usually given in aqueous infusion, one ounce in a pint, in the dose of a wineglassful.

CHAMPACA - CAMPHOR. *Champacol.* $C_{17}H_{30}O$. This camphor was first separated by Merck from *champaca-wood.* (See *Merck's Annual*, 1893, also *Schimmel's Report*, 1897, 11.

CHELONE GLABRA. L. *Snake-head. Turtle-head. Balmony. Shellflower. Chelone*, Fr., G. The leaves of this very common indigenous, perennial, herbaceous plant, of the nat. ord. Scrophulariaceæ, have a bitter taste, and are said to be tonic and aperient, with a supposed peculiar action on the liver. The decoction (two ounces of the fresh herb to the pint) may be given in the dose of one or two fluidounces (29·5 or 59 C.c.).

CHELTENHAM SALT, ARTIFICIAL. Several artificial mixtures have been prepared as imitations of the salts of the chalybeate Cheltenham water. One frequently used is equal parts of magnesium sulphate, sodium sulphate, and common salt; other formulæ contain some iron. These combinations are used as laxatives in *glandular obstructions*, especially of the *liver*, and in *scrofulous affections*, attended with feeble digestion, sluggish bowels, and pallidness of skin; also in *habitual costiveness* and *hemorrhoids.*

CHINA MORADA. Under this name there appear to be used in Bolivia several barks. One of these has been ascertained by Messrs. Arati and Canzoneri (*L'Orosi*, Feb. 1889) to be the product of a rubiaceous tree, *Pogonopus febrifugus*, and to contain an alkaloid, *moradeine*, besides a fluorescent substance, *moradin*, allied to scolopetin. (See *P. J. Tr.*, xix.)

CHINAPHTOL. *β-Naphtol-α-monosulphonate of Quinine.* $C_{20}H_{24}N_2O_2.(C_{10}H_6OHSO_3H)_2$. This substance is a yellow crystalline powder, of a bitter taste, insoluble in cold water, moderately soluble in hot water and alcohol, which has been proposed by Dr. E. Riegler (*Wien. Med. Blatt.*, xix., 1896) as an antipyretic and intestinal antiseptic. He states that it is decomposed by the alkalies of the intestinal juices into its constituents, —namely, quinine and β-naphtol sulphuric acid; and that he has used it up to five grammes a day with satisfaction in acute *rheumatism* as well as in *typhoid fever.* It contains about 42 per cent. of quinine.

CHINOIDINUM. *U. S.* 1880. *Chinoidin. Quinoidin. Chinoidine. Quinoidine. Precipitated Extract of Bark. Amorphous Quinine. Quinine brute ou amorphe*, Fr. The term chinoidine was first applied to all of the amorphous alkaloids found in and existing naturally in cinchona bark, but it is now used to define a complex body consisting not only of the natural amorphous alkaloids, but those which are artificial and accidental in the derivative products resulting from the application of heat. Upon the evaporation of the mother-liquor left after the crystallization of the quinine sulphate in the preparation of that salt, a dark-colored substance is obtained, having the appearance of an extract. Sertürner supposed that he had discovered a new alkaline principle in this product; but his conclusions were invalidated by the experiments of MM. Henry and Delondre, which went to prove that the alkaline matter contained in it consisted of quinine and cinchonine, obscured by admixture with a yellowish substance that interfered with their crystallization. Nevertheless, under the name of *quinoidine* or *chinoidine*, given to the supposed new alkaloid by Sertürner, there has been long employed in Europe a substance precipitated from the mother-liquor of quinine sulphate by means of an alkaline carbonate, having a yellowish-white or brownish color, and, when moderately heated, agglutinating into a mass of resinous appearance. By the conjoint labors of F. L. Winckler, of Liebig, and of Pasteur, it has been proved that ordinary quinoidine, or amorphous quinine, consists of two alkaloids, derivatives from quinine and cinchonine, with which they are respectively isomeric, though differing in being uncrystallizable, and named, in view of their origin, *quinicine* and *cinchonicine.* The pure amorphous quinine of Liebig is the former of these alkaloids. The *amorphous quinine*, as Liebig calls it, is entirely soluble in diluted sulphuric acid and in alcohol; and, if its solution in a diluted acid yield upon the addition of ammonia exactly as much precipitate as there was of the original substance dissolved, it may be considered pure. (*A. J. P.*, xviii. 181.) We have been informed that, in an extensive chemical manufacturing establishment in Philadelphia, the loss by quinoidine in the preparation of quinine sulphate has much diminished since the introduction of steam heat, showing the agency of heat in converting the crystallizable into the uncrystallizable salt; by the use of vacuum apparatus this loss is still further diminished.

The U. S. Pharmacopœia of 1880 described chinoidine as "a brownish-black or almost black solid, breaking, when cold, with a resinous, shining fracture, becoming plastic when warmed, odorless, having a bitter taste and an alkaline reaction. Almost insoluble in water, freely soluble in alcohol, chloroform, and diluted acids; partially soluble in ether and in benzol. The solutions have a very bitter taste. If Chinoidin be triturated with boiling water, the liquid, after filtration, should be clear and colorless, and should remain so on the addition of an alkali (abs. of alkaloidal salts). On ignition, Chinoidin should not leave more than 0·7 per cent. of ash."

A simple method of purification consists in dissolving the chinoidine in diluted hydrochloric acid, adding water and precipitating with an alkali, washing and drying.*

* The following process has been adopted by the Dutch Society for the Advancement of Pharmacy. Digest one part of chinoidine with two parts of benzol on a water-bath. Pour off the clear solution and wash the residue with one part of benzol. Agitate the united clear liquids with a small excess of diluted hydrochloric acid, allow the mixture to subside, remove the acid liquid, and add solution of soda until fairly alkaline. A portion of the filtered solution is

Tinctura Chinoidini is made, by the German Pharmacopœia, by simply dissolving 3 parts of chinoidine in one of hydrochloric acid and 17 of alcohol, sp gr. ·894.

Chinoidine Hydrochloride is made by heating 1 part of the purified chinoidine with 4 parts of distilled water, adding sufficient diluted hydrochloric acid to complete the solution, filtering, evaporating, and powdering the residue. Zimmer furnishes the German market with the purified hydrochloride, under the name of *Chininum amorphum muriaticum purum.* It has been largely used medicinally. For formulas for various salts of chinoidine, see *N. R.*, 1882, 11, or *Proc. A. P. A.*, 1882, 417.

Chinoidine is undoubtedly possessed of decided antiperiodic properties, but in these it is inferior to the cinchona alkaloids. It is, moreover, much more apt to disagree with the stomach, and is uncertain in its dose, so that, notwithstanding its great cheapness, it is but rarely used. From thirty grains to a drachm (1·9–3 9 Gm.) may be given in the interparoxysmal periods of *an intermittent*, and its action closely watched.

CHINOL. *Quinoline mono-hypochlorite.* C_9H_6 N.Cl.O. A white crystalline powder, odorless, having a pungent but not disagreeable taste. It is almost insoluble in cold and hot water, but quite soluble in alcohol. This substance is said to be actively antipyretic and analgesic, useful for the purposes for which antipyrin is employed. Dose, from three to five grains (0·19–0·32 Gm.).

CHINOLINE. *Quinoline. Leucoline. Chinoline*, Fr. *Chinolin*, G. (C_9H_7N.) This is an artificial alkaloid prepared by the destructive distillation of quinine or cinchonine with potassium hydrate, and also synthetically by König's and Skraup's processes by the action of sulphuric acid and glycerin upon nitrobenzol and aniline, or a mixture of these two latter substances. Quinoline is a colorless, strongly refractive oily liquid, having a specific gravity of 1·081 at 10° C. (50° F.) (Hofmann), boiling at 235·6° C. (456·8° F.) without decomposition; the oily stain left on bibulous paper disappearing readily on exposure. Its odor is aromatic, resembling that of oil of bitter almond. It is sparingly soluble in cold water, more so in hot water, soluble in alcohol, and mixes in all proportions with ether, carbon disulphide, methylic alcohol, etc. It easily dissolves camphor and resin. It gradually turns reddish brown in color on exposure to the air. It forms readily crystallizable salts with acids, the tartrate now being a commercial article; these salts are decomposed by contact with fixed alkalies and the peculiar odor of chinoline developed. Ekin (*P. J. Tr.*, Feb. 11, 1882) found a sample of commercial German quinoline to consist largely of a mixture of aniline and nitrobenzol, although labelled pure. *Quinoline tartrate* is in the form of a whitish, micaceous, crystalline powder, melting at 125° C. It dissolves in 80 parts of cold water, in about 150 parts of alcohol, and in 300 parts of ether, having a peculiar pungent odor and a rather sharp though not unpleasant taste. *Quinoline hydrochlorate* melts at 94° and sublimes unchanged. It dissolves in water, alcohol, and chloroform. *Quinoline salicylate* is a white crystalline powder, soluble in water and in glycerin, very soluble in alcohol, ether, vaseline, and fatty oils.

Quinoline was first brought forward as a substitute for quinine by Julius Donath, of Hungary. (*Ber. Deutsch. Chem. Gesell.*, xiv. 1769.) It appears to be a powerful antipyretic and a stronger antiseptic even than carbolic acid, and to act as a powerful depressant upon the central nervous system. A 1 per cent. solution completely destroys the coagulability of the blood. Quinoline was at first used by various Continental physicians with alleged excellent results in *malarial fevers*, but subsequent experience showed that the drug is only feebly, if at all, antiperiodic, and very apt to disagree with the stomach. The tartrate was given in doses of fifteen grains (0·97 Gm.). It has been highly commended as a preservative for anatomical specimens. The formula adopted in the Erlangen Physiological Institute is: quinoline, 5 grammes; sodium chloride, 6 grammes; glycerin, 100 grammes; water, 900 grammes. The ordinary tar quinoline can be used. The liquid is said to have the advantage of preserving all the tissues in their natural condition, except that it removes from them all coloring matter.

For a paper on the physiological activities of various derivatives of chinoline, by Ralph Stockman, see *Trans. College of Physicians*, Edinburgh (Laboratory), 1893.

CHINOSOL. *Quinosol.* $C_9H_6ON.SO_3K + Aq.$ *Potassium Oxyquinoline Sulphonate.* This is a neutral compound of oxyquinoline which readily liberates the latter in a nascent condition, and thus possesses very active antiseptic properties.

It is a crystalline yellow powder, very soluble in water, insoluble in alcohol and ether, having a feeble aromatic odor. Its aqueous solution when very dilute strikes with ferric chloride a lively green color.

Chinosol does not precipitate albumin, is affirmed to be very slightly toxic, unirritating, and possessed of an extraordinary power of penetrating tissues. It has been commended by a large number of German and English clinicians as a very advantageous antiseptic, which even exceeds in power corrosive sublimate; but Giovanni asserts that in regard to the chancre poison it is inferior to carbolic acid. The bacillus of the plague Moor found to be killed by it in ten minutes in a dilution of 1 to 500. It has been very highly recommended by Gilles and others in the treatment

now tested by adding a few drops of concentrated solution of sodium hyposulphite; if a precipitate occurs which does not disappear on further dilution with water, the solution has not been sufficiently purified; then the whole solution must be purified by adding hyposulphite until a permanent precipitate is no longer produced. The liquid is then heated on a water-bath, mixed with solution of soda in excess, the precipitate washed with water, and dried. (*N. R.*, 1882, 11.)

The objection to the above process is, that it is sometimes difficult to entirely get rid of the odor of benzol. Dr. J. E. De Vrij proposes the following improvement. One hundred parts of chinoidine are boiled during ten minutes with a diluted solution of soda, with constant stirring. When cold, the alkaline liquid is poured off, and the remaining chinoidine washed with a little water. Three hundred parts of water are now added to the washed chinoidine, the whole heated to boiling, and then mixed very slowly with the *least necessary quantity of nitric acid* to obtain a homogeneous dark-colored solution; great care must be observed not to add one drop too much of nitric acid. The still alkaline liquid is set aside for twelve hours to separate. The upper layer is poured off as clear as possible, and the lower layer washed with water until a brownish-black insoluble mass remains, which is worthless. The united liquids are filtered, water added, and if turbidity results, still more water until the addition ceases to produce cloudiness. The liquid is then filtered, and an excess of soda added, which precipitates the chinoidine. This is washed with water, and the mass heated carefully until free from water. (*Amer. Drug.*, 1884, 134.)

of *vaginitis* and other affections of the female genital organs, in the form of douches of 1 to 1000 to 1 to 8000; also as a local application in *leprosy*, in *lung* and *bone tuberculosis*, and, mixed with from 5 to 10 per cent. of boric acid, as a powder to be used as a substitute for iodoform. Schifferdecker states that the irrigation of cadavers through their arteries with a 5 per cent. solution is an effective means of preservation.

As a disinfectant to the hands, skin, and suture threads, according to F. Hobday, Chinosol may be used in as strong solution as 1 in 60, without the production of irritation of skin or wound. On the other hand, it rapidly attacks surgical instruments, taking off their edge and causing greenish-black spots upon them. Internally it has been especially used by A. G. Cipriani in the treatment of *tuberculosis*, both by mouth and injected locally. (*Allgemeine Medicin Central-Zeitung*, Bd. lxvi.) It is probably more toxic than has been generally supposed, since in Hobday's experiments a dose of one-sixteenth of a grain for each pound of body weight was found to be the extreme limit that could be given to cats without serious danger. As a local application the strength most generally useful is probably from one-half to one grain to the fluidounce; although to a very badly infected wound a solution of 1 to 500 may be often applied once, twice, or three times a day with great advantage.

CHINOTOXINE. *Dichinolindimethylsulphate.* This synthetic compound is said to possess properties similar to those of curare.

CHIONANTHUS VIRGINICA. L. *Fringe Tree.* (Nat. ord. Oleaceæ.) In the bark of this indigenous plant saponin was found by Mr. R. S. Justice. (*A. J. P.*, xlvii. 195), but not by W. von Schulz, who, however (*Pharm. Zeit. f. Russl.*, 1893, 579), detected a glucoside. The fluid extract has been recommended in doses of from one-half to one fluidrachm (1·84–3·69 C.c.) two or three times a day, as an aperient and a diuretic.

CHLORAL-AMMONIUM. $CCl_3.CH(NH_2)OH$. *Trichloramido-ethylic Alcohol.* This substance is said by Dr. W. B. Nesbit to act as chloral, but to be stimulant to the circulation in doses of from five to twenty grains (0·323–1·3 Gm.). For method of preparation, see *T. G.*, 1888.

CHLORAL-CAMPHOR. *Camphorated Chloral.* This is a thick, oily liquid, obtained by rubbing up equal parts of camphor and chloral. It distils slowly without change, and dissolves in 60 per cent. alcohol, from which it is precipitated by the addition of water. (*A. J. P.*, 1886, 282.) Chloral-camphor is used in *neuralgia* as a counter-irritant and local anæsthetic. Conflicting opinions have been expressed about the character of this liquid, the fact that both substances could be obtained unchanged by precipitating its alcoholic solution with water being regarded as proof of its being simply a mechanical mixture. Cazeneuve and Joubert believe, however, that chemical combination has been effected, and point to its optical behavior as proof. (See *Chloral Camphoratum*, *N. F.*)

CHLORAL CARBAMIDE. When 165·5 parts of the hydrate of trichloraldehyde are mixed in a porcelain mortar with 60 parts of carbamide (urea), the mixture liquefies. On dissolving this substance in three times its quantity of water warmed to 60°, and then allowing the mixture to cool, a crystalline mass, chloral carbamide, is obtained. This substance dissolves readily in warm water and in alcohol, and less readily in warm alcohol. According to Kobert, it acts like chloral, but is too slow and uncertain to be of practical value.

CHLORAL-CARBOL. *Carbolated Chloral.* According to Boureiz, when chloral hydrate and carbolic acid are rubbed up in the proportion not exceeding one to one and four-tenths parts, a liquid is obtained which has the sp. gr. of about 1·5, and is soluble in all proportions in water, alcohol, and ether. (*P. J. Tr.*, xvi. 188.) When applied locally it is a counter-irritant and local anæsthetic.

CHLORAL CYANHYDRATE. This is a compound first prepared by Messrs. Pinner and Bischoff, and recommended by Mr. Hermes (*Pharm. Centralh.*, Aug. 1887) as a substitute for hydrocyanic acid, whose physiological action it is stated to share. Chloral cyanhydrate is represented by the formula $CCl_3-CH-\begin{cases} OH \\ CN \end{cases}$, and is described as a crystalline powder, consisting partly of colorless prisms and partly of rhombic tables, fusing at 61° C., easily soluble in water, alcohol, and ether. With the vapor of water it volatilizes in small quantity, and breaks up into its components, chloral and hydrocyanic acid. It is also decomposed by alkalies, with the re-formation of hydrocyanic acid. Its aqueous solutions remain unaltered for a long time. Six and a half parts by weight of chloral cyanhydrate correspond with one part of anhydrous hydrocyanic acid.

CHLORAL-MENTHOL. *Mentholated Chloral.* This is obtained by triturating together equal weights of chloral and menthol, and heating gently in a water-bath until liquefied. It is an oily, colorless liquid, with a distinct mint-like odor and warm taste, having a specific gravity of 1·1984. It is freely soluble in alcohol, chloroform, and benzin. (*A. J. P.*, 1886, 283.) Chloral-menthol has been used as a counter-irritant and local anæsthetic in facial and other *neuralgias*.

CHLORAL-URETHANE. *Uralium*, $CCl_3.CH\begin{cases} OH \\ NHCO_2C_2H_5 \end{cases}$, is a compound of chloral and urethane. It is insoluble in cold water, and is decomposed by boiling water; it is soluble in alcohol and ether, and melts at 103° C. According to G. Poppi (*Riforma Medica*, 1889), this substance as an hypnotic is equal to chloral, and has the superiority of not acting on the heart and of being tolerated better. J. Schmitt, however (*Revue Méd. de l'Est*, May, 1890), finds that it does act upon the heart, arresting it in diastole, and resembling very closely chloral in its physiological action, and having the inconvenience of great insolubility. J. Schmitt and P. Parisot (*Revue Méd de l'Est*, Dec. 1890) find that unless given in doses of fifteen and a half grains (1 Gm.) it is very uncertain in its action as a medicine, and is apt to disagree with the stomach, being on the whole inferior to chloral.

CHLORALAMIDE. (*Chloral formamide*), $CCl_3.CH\begin{cases} OH \\ CONH_2 \end{cases}$, is formed by the action of formamide upon chloral. Lustrous, colorless crystals, with somewhat bitter taste; melting point 115° C.; decomposed at a somewhat higher temperature; soluble in about 20 parts of cold water or in 1½ parts of 96 per cent. alcohol; is decomposed by water at 60° C. or by alkalies, but not by dilute acids.

When given to the lower animals, chloralamide produces lethargy, sleep, muscular relaxation, arrested respiration; followed by coma, failing respiration, and, if the dose has been sufficient, death by paralysis of the respiratory centres. In the experiments of Drs. H. C. Wood and Cerna (subsequently confirmed by various observers) the influence of chloralamide upon the circulation was very feeble, no distinct effect being produced except after the largest toxic dose. The action of the drug upon the spinal cord was also very feeble, and no perceptible influence could be made out upon the nerves and muscles. On the other hand, the effect of the drug upon the cerebral cortex was very pronounced. As an hypnotic in man, chloralamide resembles chloral closely, but is somewhat slower and less certain in its action than is chloral. It usually does not produce any unpleasant after-effects, though confusion, giddiness, and headaches have been occasioned in some cases. It does not seem to be more irritating than is chloral. The assertion of various clinicians that it is safer than chloral in cases in which there is cardiac weakness is borne out by studies of its physiological action. When *insomnia* is produced by pain it is of little use. It has been found successful in quieting *hysteria*. The toxic dose of chloralamide depresses the heart and the spinal cord. No severe cases of poisoning have been reported from it. It is eliminated in the form of uro-chloralic acid. Dose, from half to one drachm (1·9–3·88 Gm.), administered in aqueous solution or capsules, half an hour before the expected time of sleep.

Chloralimide, $CCl_3.CH{=}NH$, should not be confounded with Chloralamide. Chloralimide is in colorless, inodorous, and insipid, long crystalline needles; melting at about 166° C. (330·8° F.); insoluble in water; readily soluble in alcohol, in ether, in chloroform, and in oils. Concerning its physiological action we have no certain knowledge; it is asserted to be hypnotic in doses of from fifteen to sixty grains (0·9–3·8 Gm.).

CHLORALOSE. $C_8H_{11}Cl_3O_6$. *Anhydro-glucochloral.* When equal parts of anhydrous chloral and glucose are heated together for an hour at the temperature at which chloral boils, two isomeric substances—*chloralose*, which is soluble, and *parachloralose*, which is insoluble—are formed. Chloralose occurs in small crystals having a very bitter and disagreeable but not acrid taste. It is freely soluble in alcohol and in hot water, slightly so in cold water, a little less than five grammes to the litre. Its melting point is 185° C. Chloralose was first brought forward as a remedial agent by Hanriot and Richet (*Bull. Soc. Biolog.*, 1893), who state that five grammes of it will produce in a dog of ten kilogrammes' weight symptoms of intoxication, followed by a most profound sleep, in which all sensibility is lost, although the reflex activities are greater than normal. Upon the circulation the drug has but little power, the arterial pressure, even when there is profound anæsthesia, being scarcely affected. During the anæsthesia not only was the spinal motor side of the cord more active than normal, but the motor cerebral cortex was found to be excessively excitable, the animals experimented upon offering a strong contrast with chloralized dogs, in which the psychomotor cortex was almost devoid of responding power.

As a practical hypnotic, the action of chloralose is very variable and is often attended by disagreeable results, ten grains frequently failing to cause sleep, although the same amount has produced complete unconsciousness with alarming symptoms. Partial general paralysis, tremors, great slowing of the pulse, and marked evidences of enfeebled heart action have not rarely followed the use of the drug; whilst involuntary discharges of urine, delirious intoxication, excessive vomiting, and other disagreeable symptoms have been noted. The dose is from five to ten grains (0·32–0·65 Gm.), given in capsules.

Dr. M. H. Rendu (*Bull. et Mém. de la Soc. Méd. de Hôp. de Paris*, xx. 1895), has reported violent collapse, excessive rapid feeble pulse, pronounced disturbance of respiration, epileptiform convulsions, and collapse as produced by twenty-five centigrammes of chloralose.

CHLORALOXIMES. A series of compounds, whose strong physiological activities are asserted to be due to their splitting up in the system into chloral hydrate and their respective oximes. They are *chloralacetoxime* (melting point, 72° C.); *chloralcamphoroxime* (melting point, 98° C.); *chloralnitroso β-naphtol* (melting point, 100° C.); *chloralacetaldoxime* (melting point, 74° C.); *chloralbenzaldoxime* (melting point, 62° C.). The compounds are easily soluble in alcohol and ether, and are readily recrystallized from petroleum ether. Water dissolves them with difficulty, and when applied hot is apt to cause decomposition and the re-formation of chloral hydrate. (*Deut. Chem. Zeit.*, 1892.)

CHLORINATED ANÆSTHETIC COMPOUNDS. *Bichloride of Ethylene. Ethene Dichloride. Dutch Liquid. Æthyleni Bichloridum. Æthylenum Chloratum. Elaylum Chloratum. Liquor Hollandicus. Liqueur des Hollandais, Huile du Gas oléfiant*, Fr. *Aethylenchlorid, Elaylchlorid*, G. $C_2H_4Cl_2$. By the mutual action of chlorine and olefiant gas an oily liquid is obtained, discovered by four associated Dutch chemists, and called *Dutch liquid*. The Dutch liquid has been tried as an anæsthetic by Prof. Simpson and Mr. Nunneley. Prof. Simpson was not satisfied with its effects; but Mr. Nunneley, having administered it frequently in practice, found it perfectly agreeable in every respect. Its use, he alleges, is not attended by the troublesome excitement produced by ether, or by the tendency to collapse caused by chloroform. Two forms of the Dutch liquid have been experimented with by Dr. Aran, of Paris; and one of them furnished very satisfactory clinical results. The liquid which gave the favorable results has been ascertained by Mialhe and Flourens to be the monochlorinated Dutch liquid (*monochlor-ethylene chloride*, $CH_2Cl,CHCl_2$), but its cost proved to be too high to allow of its general use at that time as a therapeutic agent. In consequence of this objection to the monochlorinated liquid, Mialhe and Flourens were induced to search for a substitute in the corresponding compound of a parallel series of ethers, formed by the action of chlorine on hydrochloric ether. When ethyl chloride (hydrochloric ether, C_2H_5Cl) is acted on by successive portions of chlorine, the hydrogen is replaced by the latter, atom for atom, and there are formed the five following compounds: $C_2H_4Cl_2 - C_2H_3Cl_3 - C_2H_2Cl_4 - C_2HCl_5 - C_2Cl_6$. Of this series, the first member is isomeric with the Dutch liquid; the second, third, and fourth with the mono-, bi-, and

trichlorinated Dutch liquid, and the fifth is a chloride of carbon, frequently called the "sesquichloride of carbon." The first member, though identical with the Dutch liquid in elementary composition and having a vapor of the same density, has, nevertheless, a lower boiling point,—60°–64° C. (148° F.), while the Dutch liquid boils at 84·9° C. (185° F.),—and is different in chemical properties. Thus, it is not decomposed by an alcoholic solution of potassa, as the Dutch liquid is, and is not acted on by potassium, while the Dutch liquid is immediately attacked by it. The explanation of these facts is that the two compounds, while *isomeric*, or having the same empiric formula, are differently constituted molecularly. Thus, Dutch liquid is known chemically as *ethene dichloride*, CH_2Cl,CH_2Cl, while the chlorinated ethyl chloride is known as *ethylidene chloride*, $CH_3,CHCl_2$. This difference of molecular structure, of course, runs all through their derivatives until the final product C_2Cl_6 is reached in both cases, and here there is identity of product.

The conclusion arrived at by Mialhe and Flourens appears to be that the four chlorinated hydrochloric ethers all possess anæsthetic properties; and, as it would be difficult to separate them, they propose the use of the mixed ethers, consisting principally of the tri- and quadrichlorinated compounds, as an anæsthetic, under the indefinite name of *chlorinated muriatic ether*. Since the time of Mialhe and Flourens's experiments, the matter has been taken up again, and Dr. Taube (*A. J. P.*, 1880, 603, and 1881, 119) has proved the availability as anæsthetics of monochlorethylidene chloride, CH_3,CCl_3, and of monochlorethylene chloride, $CH_2Cl,CHCl_2$.

The precise action of the various ethers upon the organism is at present unknown. The committee of the British Association found (*Brit. Med. Journ.*, i., 1879) the ethene dichloride ("formerly named *ethylene* dichloride, or Dutch liquid, $C_2H_4Cl_2$") to cause convulsions in the lower animals; whilst E. T. Reichert (*Phila. Med. Times*, xi. 518) has found that the "ethylene dichloride" produces anæsthesia with the usual stages, and that, like chloroform, it depresses the heart and steadily lowers the arterial pressure. His experiments seem to show, however, that its action upon the heart is much less powerful than that of chloroform, and in all of his trials the animal died of centric respiratory paralysis whilst the heart was still maintaining some degree of circulation. He believes, therefore, that it is a much safer agent than chloroform, ranking it between the latter and ether. It is evident that Dr. Reichert was not using the same agent as the English committee were, but exactly what he did have is uncertain.

The above bodies are produced sometimes on a considerable scale in the manufacture of chloral. A very variable mixture of the middle members of the series is at present an article of commerce under the name of *Liquor anæstheticus*. Another similar mixture containing the less chlorinated bodies is the *Æther anæstheticus Aranii*, boiling between 84° C. (183·2° F.) and 103° C. (217·4° F.). The *Æther anæstheticus*, Wiggers, contains the more highly chlorinated products.

Ethylidene Chloride, *Chlorinated Muriatic Ether*, *Ethydene Chloride* ($CH_3,CHCl_2$), is a colorless, very mobile, neutral liquid, having an aromatic ethereal odor, and a hot, saccharine taste. It is sparingly soluble in water, but readily soluble in alcohol, ether, and most of the fixed and volatile oils. It is not inflammable, in which respect it agrees with chloroform. When purified it is a liquid somewhat resembling chloroform, of sp. gr. 1·174 at 17° C., boiling at 60° C., and not miscible with water. It can be distinguished from chloroform in that it combines with chlorine even in the dark, liberating hydrochloric acid. According to Flourens, its action is similar to that of chloroform. It has been studied to some extent by the British Association Committee (*Brit. Med. Journ.*, 1879, i.), who believe it to be a most valuable anæsthetic, exerting little or no depressing effect upon the heart; but the work of the committee was not sufficiently thorough to be conclusive. Many years ago Snow used it on man, and gave judgment in its favor, and recently Binz has produced anæsthesia with it in the same way satisfactorily, and thinks it increases the circulation (*Lond. Med. Times and Gaz.*, 1879, i.); but Reeve finds (*N. R.*, 1880, 334) that in animals it lowers the arterial pressure, but does not suddenly paralyze the heart, as does chloroform. It is extremely probable that the liquid used by Dr. Reichert was this substance, and not the ethylene dichloride, as he thought. (See *Ethylene Dichloride*.)

Within a very short time various other chlorinated compounds have been brought forward as having anæsthetic virtues, of which those most deserving of attention are probably *methylene dichloride* and *carbon tetrachloride*. It will be more convenient to consider these under the general name at the head of this article, than to scatter them here and there according to the position of their titles in an alphabetical catalogue.

Methylene Dichloride. *Dichloro-methane. Bichloride of Methylene.* CH_2Cl_2. This was introduced by B. W. Richardson, of London. It may be prepared by exposing to sunshine, in a glass globe, pure chlorine and gaseous methyl chloride. The globe has two lateral apertures for the admission of the gases, and below an open neck, which communicates with one of the tubulures of a Woulfe's bottle, of which the other tubulure communicates by a bent tube with a second Woulfe's bottle, and this by another bent tube with a flask. The second bottle is surrounded with ice, and the flask immersed in a freezing mixture, to condense the volatile products. The dichloride condenses in the flask in a pure state, while the contents of the two Woulfe's bottles consist chiefly of chloroform. (*Gmelin*, vii. 288.)

The methyl chloride may be made for this purpose by heating together 1 part of wood-spirit, 2 parts of common salt, and 3 of sulphuric acid, and collecting the evolved gas over water, which retains the impurities. Methyl chloride is a colorless gas, having an ethereal odor and a sweetish taste. (Gmelin.) Richardson found it to possess anæsthetic properties, but to be less manageable than the methylene dichloride. It has been since made more practically by reducing chloroform (trichlormethane) in alcoholic solution by zinc and by hydrochloric acid, the product being mixed with water; the specifically heavier liquid separates and is purified by successive treatment with soda solution, sulphuric acid, water, calcium chloride, and fractional distillation.

Methylene dichloride is a colorless liquid, of an odor analogous to that of chloroform, of the sp.

gr. 1·344, and the boiling point 40° C. (104° F.). The density of its vapor is 3·012 (Gmelin), 2·937 (Richardson). In its preparation the chlorine replaces one atom of hydrogen in the methyl chloride; thus converting the CH_3Cl (methyl chloride) into CH_2Cl_2 (methylene dichloride). The vapor of the dichloride does not, like that of chloroform, extinguish the flame of a taper, but itself takes fire, burning with a brilliant flame, and yielding, as the result of its combustion, carbonic and hydrochloric acids. Methylene dichloride mixes readily with absolute ether, and, as the boiling points of the two approach nearly, they volatilize evenly and equably. It is neutral to test-paper; and an acid reaction in any specimen would be an evidence of the presence of hydrochloric acid, and should preclude its use as a respiratory anæsthetic. To prevent the generation of the acid, the liquid should be kept carefully secluded from the sunlight, and the addition of a small quantity of absolute alcohol is recommended.

In his experiments upon the lower animals, Richardson found that methylene dichloride was a powerful anæsthetic, in which he believed he had discovered certain advantageous properties, making it practically more powerful than chloroform. He asserted that the narcotism is produced more rapidly and continued longer than when caused by other anæsthetics, passing off, however, with great suddenness; and that general muscular irritability is affected less by the dichloride than by other anæsthetics; also that its influence upon the respiration and circulation is more uniform and more equal than other anæsthetics. (*Med. Times and Gaz.*, 1867.) As the result of the paper of Dr. Richardson, the dichloride was used as an anæsthetic by various English surgeons, also in Germany and America.

Judging from its chemical constitution, methylene dichloride, containing less chlorine than chloroform, should be the safer of the two agents. It may very well be that the deaths which have occurred from it have been due to the commercial drug being something else than it purported to be. Some years ago H. C. Wood had examined in the chemical laboratories of the University of Pennsylvania methylene dichloride, supplied by one of the most reputable of the English manufacturing chemical firms, and sold as first quality. It contained, however, little or none of the methylene dichloride, and was largely chloroform. Gutzart states, as the result of examination of German specimens of the drug, that they are mixtures of alcohol, methylene dichloride, and chloroform in varying proportions. It seems even probable that Dr. Richardson did not have the pure article. The experiments of Geuther and Eichholz, and of Heymanns and Debuck (*Arch. de Pharmacod.*, i.) show that the dichloride acts upon guinea-pigs and rabbits similarly to chloroform, but that chloroform is twice as poisonous to the heart. It is possible that methylene dichloride has advantages over chloroform, but the high price of the pure drug must interfere with its use. Any commercial article offered below price may be relied upon as impure. The quantity used by Richardson averaged a drachm (3·88 Gm.) every five minutes. Experience has shown the fallaciousness of the first estimates of its safety, as several deaths have been produced by it. (See *British Med. Journ.*, Oct. 1869; *Dublin Quarterly Journ.*, Aug. 1870; *P. J. Tr.*, 1871, 875.) Even the mixture of methylene dichloride and absolute ether, which Dr. Richardson has introduced under the name of *methylene ether* (*Med. Times and Gaz.*, ii. 1872; i. 1873), has caused death. (*Phila. Med. Times*, iii. 718; *Med. Times and Gaz.*, July, 1873.)

The methylene dichloride may be given internally in the dose of from ten to thirty minims (0.62–1·85 Gm.) or be given in dilute spirit.

Carbon Tetrachloride. *Tetrachlor-methane. Carbonei Tetrachloridum. Carboneum Chloratum. Chlorocarbon. Tétrachlorure de Carbone, Formène Perchloré*, F. *Chlorkohlenstoff*, G. This substance, though discovered by Regnault so early as 1839, did not come into general notice until December, 1865, when it was suggested as an anæsthetic by Simpson, of Edinburgh. (*Med. Times and Gaz.*, Dec. 1865.) It had, however, been previously used as an anæsthetic by A. E. Sansom and John Harley, who experimented with it in 1864, and recorded their experience in Sansom's work on Chloroform, published in May, 1865. (*B. and F. Med.-Chir. Rev.*, 1867, 551.) To procure it, dry chlorine is passed first through a bottle containing carbon disulphide, and then through a porcelain tube filled with pieces of porcelain and kept at a bright red heat. The vapors are condensed in a well-cooled receiver, forming a yellowish-red liquid, which is a mixture of carbon tetrachloride and sulphur chloride. The sulphur chloride is removed by slowly adding the liquid to an excess of potash lye or milk of lime; the mixture being set aside, and agitated from time to time till the sulphur compound is decomposed, and then distilled. A recent patent claims that by heating together carbon disulphide and sulphur chloride, S_2Cl_2, in the presence of small quantities of iron, carbon tetrachloride is formed by the following reaction: $CS_2 + 2S_2Cl_2 = CCl_4 + 6S$. There are other modes of preparing it, which may be found in *Gmelin's Handbook* (vii. 356). By one of these chloroform is made to yield it by the substitution of an atom of chlorine for one of hydrogen; thus $CHCl_3$ (chloroform) becomes CCl_4 (carbon tetrachloride).

Carbon tetrachloride is a transparent colorless liquid, of the sp. gr. 1·599 (Regnault), boiling at 77° C. (170·6° F.), with a vapor density 5·33, and an agreeable aromatic flavor. At 30° C. it solidifies to a crystalline mass.

Its formula is CCl_4, and its derivation from methane or marsh gas is expressed in the term *tetrachlormethane*. P. Smith describes its effects as follows. About half a drachm (1·85 Gm.) on a handkerchief was inhaled. The vapors had a quince-like odor, with a sense of coolness in the fauces, followed by a feeling of calmness and comfort. A very rapid and fugacious anæsthesia was produced by a larger dose. Small doses of the carbon tetrachloride caused in animals entire loss of power and consciousness, from which they soon recovered entirely; but larger doses occasioned death; the animal becoming first unconscious, then gradually ceasing to respire, and dying in eight minutes. The heart was not felt to beat after the breath had ceased. Similar experiments were performed by John Harley with essentially similar results. From numerous trials afterwards made on human subjects, the conclusion was arrived at, that the carbon tetrachloride may be usefully employed, by inhalation, for the relief of pain, especially *headache, tic douloureux, toothache, dysmenorrhœa*, etc.,

but the remedy has not come into practical use. Like all anæsthetics, carbon tetrachloride may destroy life if recklessly used. (*Lancet*, June 1, 8, and 29, 1867.)

Sir J. Y. Simpson says, of this anæsthetic, that the effects of its vapor approach near to those of chloroform, but its depressing influence on the heart is far greater, and, consequently, its employment far more dangerous. Its vapor, applied to the eye by sprinkling a few drops on the hand, is asserted to be an effectual means of relieving some forms of *conjunctivitis*, *ulceration of the cornea*, *photophobia*, etc. Injected subcutaneously, in the dose of from ten to twenty drops, it relieved pains in the walls of the chest and abdomen without subsequent nausea. Internally, Sir James tried it only in small doses in *gastrodynia*, in which it had the same effects as chloroform. (*Med. Times and Gaz.*, 1865, 651.)

CHLORINATED POTASSA, SOLUTION OF. *Liquor Potassæ Chlorinatæ. Chlorure de Potasse*, Fr. *Chlorkalilösung*, G. *Javelle's Water. Eau de Javelle.* This is prepared from potassium carbonate precisely as the solution of chlorinated soda from sodium carbonate, and probably has an analogous composition. (See *Liquor Sodæ Chloratæ.*) It is employed for taking out fruit-stains, etc., from linen.

CHLORPHENOLS. $C_6H_4Cl.OH$. By the action of chlorine upon phenol is produced a mixture of ortho- and parachlorphenol, and by continued action trichlorphenol, $C_6H_2Cl_3.OH$. *Orthochlorphenol* is a liquid boiling at 175° C. and solidifying at 7° C.; the *parachlorphenol* forms crystals melting at 37° C. and boiling at 217° C. Both have an unpleasant, penetrating odor. *Trichlorphenol*, ($C_6H_2Cl_3OH$), which was discovered by Laurent, crystallizes in needles, which melt at 68° C. (154·4° F.) and boil at 244° C. (471·2° F.). It is easily soluble in alcohol and ether.

Medical Properties and Uses. Cech (*Journ. f. Prakt. Ch.*, Bd. xxii.) was the first to show that a mixture of three isomers of monochlor- and trichlorphenols was an extremely active antiseptic, more powerful than carbolic acid; but it is chiefly to Karpow, working in the laboratory of Prof. Nencki, that we are indebted for our knowledge of these subjects. This investigator found that metachlorphenol is poisonous to the rabbit, the minimum fatal dose being 1·08 Gm. per kilogramme, and the chief symptom violent clonic convulsions. He experimentally demonstrated that both orthochlor- and parachlorphenol escape with the urine, the urine becoming rapidly blackish on exposure to air, in combination with sulphuric acid and probably also with glyco-uronic acid; and confirmed the observations of M. Külz (*Pflüger's Archiv f. Physiol.*, Bd. xxx.) that the urine of dogs poisoned with the chlorphenols polarizes to the left. It would appear almost certain that the chlorphenols undergo at least partial decomposition in the organism, giving origin to hydroquinone, pyrocatechin, and other educts found after poisoning with carbolic acid. The action of these chlorphenols upon the general system is probably practically that of phenol. As germicides these compounds were found by Nencki to be very active, the 2 per cent. solution being stronger than the 5 per cent. phenol solution, and only a little weaker than the one-thousandth sublimate solution.

In practical medicine chlorphenols have been used by Simanoffski, by Girard, and by others. According to Girard, the 2 per cent. solution is irritant to the surface of wounds, but Simanoffski asserts that even the 20 per cent. solution in glycerin is not irritant to mucous membranes. A. Spengler (*Arch. des Sci. Biolog.*, vol. iv., 1895–96) states that the parachlorphenol acts very energetically upon the tubercular bacillus; and that its 10 per cent. glycerin solution, applied locally to the larynx, causes no irritation but an anæsthesia, which lasts some days, and is very advantageous in the treatment of *tubercular laryngitis.* These statements have been confirmed by Simanoffski. The chlorphenols have been used in *ozæna*, *gonorrhœa*, *ulceration*, and various other surgical affections, and Girard affirms that a 1 per cent. solution affects wounds favorably, and that a 2 per cent. solution affords an excellent method of sterilizing the instruments and hands of surgeons.

The *chlorsalols*, the *salicylic esters of chlorphenols*, were also studied by Nencki and found to undergo decomposition in the intestines or system, the salicylic acid or its derivatives appearing in the urine. The antiseptic properties of these chlorsalols were found to be much greater than that of salol. Girard has used them in doses of from four to six grammes a day in *cystitis* and *diarrhœa* with excellent results. Passerini has employed them in *phthisis* and in *bronchitis* by means of an inhaling apparatus, in which fifteen drops are placed on a piece of cotton; the patient inhaling with slow and deep inhalations from five to ten minutes daily. Usually at first some pulmonic irritation, and even for a day or two temporary exacerbation, occur, but the final results are said to be remarkable.

CHROATOL. *Terpin-iodo-hydrate*, $C_{10}H_{16}$. 2HI, occurs in greenish-yellow crystals, having an aromatic odor; it is insoluble in water, soluble in alcohol and glycerin, slightly soluble in ether and chloroform. It has been used externally in the treatment of *psoriasis* and other skin diseases as a dusting powder or 10 per cent. ointment.

CHROME YELLOW. *Chromate of Lead. Lemon Yellow. Leipsic Yellow. Paris Yellow.* $PbCrO_4$. This is the neutral lead chromate prepared by precipitating a solution of lead nitrate with potassium chromate. It is of a beautiful lemon-yellow color. The basic lead chromate (PbO, $PbCrO_4$) possesses a red color, and is sometimes used as a pigment. *Chrome green* is either the chromium sesquioxide or a mixture of chrome yellow and Prussian blue. The chromates are often adulterated with lead sulphate. M. Duviller (*Journ. de Pharm.*, Août, 1873, 114) detects this by heating one part of the suspected pigment with a mixture of from two to three parts of nitric acid, sp. gr. 1·420, one to two parts of water, and one-fourth part of alcohol. The chromate is all dissolved, but any sulphate present remains unaffected. Lead chromate has been used by bakers for giving a rich yellow coloring to buns; and there can be no doubt of its having produced fatal poisoning in a number of cases. Prof. John Marshall has shown that its exhibition in animals is followed by an absorption, which takes place very slowly and probably for the greater part in the intestinal tract, where the chromate enters the blood as sodium chromate; the lead, probably, as an albuminate.

CHROMIUM. Chromium was discovered by Vauquelin in 1797. Its most common ore is the

chrome iron, consisting of ferrous oxide and chromium sesquioxide. This is not an abundant mineral, the principal source of supply being at present Asia Minor. Chromium is obtained by igniting its oxide in contact with charcoal with the aid of the electric arc. It is a brittle metal, of a grayish-white color like platinum, with some lustre, and very hard, so that it scratches glass. Its sp. gr. is 5·9, atomic weight 52·4, and symbol Cr. It does not change by exposure to the air, and is with difficulty attacked by the acids. It forms with oxygen five compounds: 1, the monoxide (CrO), 2, the sesquioxide (Cr_2O_3), 3, the trioxide or chromic acid (CrO_3). Of the two others, one may be considered as a compound of the monoxide and sesquioxide (CrO,Cr_2O_3), and the other, called *perchromic acid*, is said to consist of two atoms of chromium and seven of oxygen (Cr_2O_7). Chromium combines with chlorine in two proportions, forming the dichloride and sesquichloride. The chief value of chromium in the arts is as the source of potassium bichromate and of pigments, although recently it has come into extensive use as an alloy, called *ferro-chromium*, for the manufacture of chrome steel and nickel-chrome steel.

CHRYSAROBINI OXIDUM. *Chrysarobin Oxide* is a brownish-black powder, obtained by boiling chrysarobin in water with sodium peroxide; its 5 to 10 per cent. ointment has been highly recommended by Unna in the treatment of facial, genital, and other forms of *eczema* for which chrysarobin is too irritating. It has no influence on dry eruptions.

CICHORIUM INTYBUS. L. *Chicory. Succory.* A perennial herbaceous composite plant, indigenous in Europe, but naturalized in this country, where it grows in fields, and in roads along the fences, in neighborhoods which have been long settled. It is one or two feet high, with large, compound, beautifully blue flowers, which appear in July and August, and serve to distinguish the plant at first sight. The whole plant has a bitter taste, without acrimony or any very peculiar flavor. The taste is strongest in the root and weakest in the flowers. The leaves, when young and tender, are said to be sometimes eaten as salad in Europe. Chicory is gently tonic without being irritating, and is considered by some authors as aperient and deobstruent. The decoction (two ounces of root to a pint) is said to be useful, if freely taken, in hepatic *congestion*, and even in *pulmonary consumption.*

The root is much used as a substitute for or adulterant of coffee. In preparing it, Dausse recommends that the dried root should be cut into rather large and equal pieces, which are to be roasted until they lose 140 out of 500 parts. The pieces are then easily ground in a mill, and afford a yellowish-brown powder. (*Pharm. Centralb.*, 1850, 688.) In France alone the annual consumption of chicory root amounted in 1860 to sixteen million pounds. For methods of detection in ground coffee, see *P. J. Tr.*, 1867, 141; also Allen (*Com. Org. Anal.*, 2d ed., vol. iii., part 2, 540), and Mr. J. R. Leebody (*Chem. News*, 1874, 243). A glucoside has been obtained from the blossoms of the *Cichorium Intybus* by Nietzki (*Arch. Pharm.*, (3) 8, 327), to which the formula $C_{32}H_{34}O_{19}$ is assigned. On boiling with dilute acids it yields glucose and a compound, $C_{20}H_{14}O_9$. This decomposition product seems to exist in the blossoms ready formed along with the glucoside. The *garden endive* is a species of Cichorium, denominated *C. endivia.*

CICUTA VIROSA. L. *Water Hemlock. Cowbane. Ciguë Vireuse*, Fr. *Wasserschierling*, G. A perennial, umbelliferous European plant, growing on the borders of pools and streams. It is very poisonous to most animals which feed upon it, though said to be eaten with impunity by goats and sheep. According to Wikszemski, it acts upon frogs similarly to picrotoxin, at first stimulating the convulsive centres in the medulla and producing violent general spasms, and later causing general centric paralysis. (Dragendorff, *Jahresbericht*, 1875, 494.) Upon man it operates as an acrid narcotic, producing vertigo, intoxication, and convulsions, followed by general paralysis and death. (See *Ibid.*) Infusion of galls is recommended as an antidote, but should not be relied on to the exclusion of emetics. When the plant causes vomiting, as it frequently does, fatal effects are less apt to ensue. It is said to be less poisonous dried than fresh; Van Ankum (*Journ. Pract. Chem.*, 1868, 105, 151) showed that the active principle was a resinous, chemically indifferent substance, to which the name *cicutoxin* has been given. Böhm (*Archiv f. Exper. Path.*, v. 281) has since obtained this principle pure as a thick, tenacious, amorphous substance, of acid reaction, of slight odor but disagreeable taste. The dry root yielded about 3·5 per cent., the fresh 0·2 per cent., of cicutoxin. The presence of a volatile alkaloid resembling *coniine*, and termed *cicutine*, has been observed by Wittstein and Buignet. The volatile oil, obtained by distillation, was found by Simon not to be poisonous. According to M. Julius Trapp, it is identical with the aromatic oil of cumin seeds. (*Chem. Centralblatt*, 1858, 414.) On the other hand, the alcoholic extract of the dried root operated as a violent poison upon animals. (*Annal. der Pharm.*, xxxi. 258.) At present the plant is never used internally, and rarely externally as an anodyne poultice in local pains.

Cicuta maculata, L., *American water hemlock, Musquash root, Beaver poison, Spotted cowbane*, which grows in meadows and on the borders of streams throughout the United States, is closely analogous, in botanical character and in effects, to the European species. In several instances children have been fatally poisoned by eating its root. This consists of several oblong, fleshy tubers, sometimes as long as the finger, spreading out from the base of the stem, and having a smell and taste not unlike those of parsnip. For microscopic examination of plant, see *A. J. P.*, July, 1891. Cicuta has been strongly lauded as a specific in nervous and sick *headache* (*Proc. A. P. A.*, 1858, 253), but is rarely if ever used. Mr. J. E. Young found in the seeds an organic alkaloid supposed to be identical with *coniine*. (*A. J. P.*, xxvii. 294, confirmed by R. Glenk, *A. J. P.*, 1891, 328.)

In poisoning by either of these species of Cicuta, free vomiting should be induced as speedily as possible, and symptoms met as they arise.

CINCHONIDINÆ SALICYLAS. *Cinchonidine Salicylate.* $C_{19}H_{22}N_2O.C_7H_6O_3$. This salt occurs in needles soluble at 18° C. in 766 parts of water. It is capable of producing physiologically the action of the quinine salts, and no doubt is a powerful antiperiodic, inferior, however, to the ordinary preparations of the alkaloid. It has been

recommended and considerably used as a specific in *chronic* and *subacute rheumatism*, in doses of from fifteen to twenty grains (0·971–1·29 Gm.) a day, best given in pill or capsule.

CITROPHEN. $C_3H_4(OH)(CONH.C_6H_4OC_2H_5)_3$. This compound of citric acid and *p*-phenetidin originated with Roos. It is a white crystalline powder, soluble in forty parts of water. It is used as an antipyretic, also in *migraine* and *neuralgia*. Dose, from ten to fifteen grains (0·65–1 Gm.).

CIVET. *Zibethum. Civette*, Fr. *Zibeth*, G. This is an odorous substance, obtained from two animals of the genus Viverra; the *V. civetta* or civet cat of Africa, and the *V. zibetha*, which inhabits the East Indies. It is secreted in a cavity opening between the anus and external genitals, and is collected from animals confined for the purpose. It is semi-liquid, unctuous, yellowish, becoming brown and thicker by exposure to the air, of a very strong, peculiar odor, similar to that of musk, though less agreeable and less diffusible, and of a bitterish, subacrid, disagreeable, fatty taste. When heated it becomes quite fluid, and at a higher temperature takes fire and burns with a clear flame, leaving little residue. It is insoluble in water, and only slightly soluble in ether and cold alcohol; but heated alcohol dissolves it almost entirely, depositing it again upon cooling. It contains, among other ingredients, a volatile oil, fat, and free ammonia. In medicine it was formerly employed in lieu of castor and musk; it is now used exclusively as a perfume. For analyses of commercial samples, see *P. J. Tr.*, 1897, 101.

CLEMATIS ERECTA. L. (Now *C. recta.* L.) *Upright Virgin's Bower. Clématite*, Fr. *Waldrebe*, G. A perennial European plant. The leaves and flowers have an acrid, burning taste. When bruised in a mortar they irritate the eyes and throat, giving rise to a flow of tears and to coughing; and applied to the skin they produce inflammation and vesication; hence their old name of *flammula Jovis*. The acrimony is greatly diminished by drying. Störck found this clematis to be diuretic and diaphoretic, in doses of from one to two grains (0·064–0·129 Gm.) of the extract a day, or from thirty to forty grains (1·94–2·59 Gm.) of the leaves given in infusion three times a day; and to be useful, locally and internally, in *syphilitic*, *cancerous*, and other *foul ulcers*.

Other species of Clematis have the same acrid properties; among these *C. flammula*, L., or *sweet-scented virgin's bower*, which, though a native of Europe, is cultivated in our gardens, *C. vitalba*, L., or *traveller's joy*, also a native of Europe, and several indigenous species, of which *C. virginiana*, L., or *common virgin's bower*, *C. viorna*, L., or *leather flower*, and *C. crispa*, L., have been used as substitutes for *C. erecta*, L. All these are climbing plants. Rochebrune (*Toxicol. Africaine*, i.) affirms that he has found in *C. flammula*, L., an alkaloid, *clematine*, two milligrammes of which will produce in the guinea-pig copious and frequent urination, general tremors, great disturbance of respiration, feebleness and intermittency of the heart-beat, followed in seven minutes by convulsions ending in coma and death.

From the bruised roots and stems of *C. vitalba*, L., boiled for a few moments in water to diminish their acrimony, and then digested in sweet oil for a little while, is made a preparation used locally in Europe for the *itch*. Twelve or fifteen applications are said to be usually sufficient. M. Gaube has found in this species an alkaloid, also named *clematine*, which forms with sulphuric acid a salt crystallizable in six-sided needles; also an acrid volatile oil analogous to mezereon in its properties, tannic acid, mucilage, and earthy salts. (*Journ. de Pharm.*, Août, 1869)

CNICUS ARVENSIS. Hoffm. (*Carduus arvensis.* (L.) Robs.) *Canada Thistle.* This indigenous, composite plant, to which have been attributed diaphoretic, emetic, and tonic properties, according to Herman J. Pierce (*A. J. P.*, lxviii., 1896) contains a volatile alkaloid.

COAL TAR. When bituminous coal is subjected to dry distillation, besides the incondensible gases which serve for lighting, and the charcoal left behind as *coke*, which is a valuable fuel, there are formed, through the reactions between the disengaged principles of the coal, numerous other products, necessarily more or less varying in character and amount, not only according to the kind of coal used, but also with the varying circumstances of the decomposing process. Most of these newly formed bodies, all of which are volatile, are condensed into a dark thick liquid or semi-liquid substance called coal tar. Formerly this was considered as refuse matter, but from it are now prepared substances of great value in the arts and in medicine. Our purpose is to give a condensed view of these substances. For greater details, see *A. J. P.*, vol. xxxiii., 39, 129, 245; also Lunge, *Coal-Tar and Ammonia*, 2d ed., London, 1887. The composition of coal tar varies considerably with the temperature at which the distillation of the coal is effected, the yield of solid bodies and of gases being larger when the temperature is higher, while at a lower temperature the liquid portion of the tar is in increased amount. When coal tar is submitted to distillation and rectification, it yields the following products, solids, liquids, and gases, in variable proportion:

1. *Solids.* Naphthalene, $C_{10}H_8$, methyl-naphthalene, $C_{11}H_{10}$, acetyl-naphthalene and diphenyl, $C_{12}H_{10}$, fluorene, $C_{13}H_{10}$, anthracene and phenanthrene, $C_{14}H_{10}$, fluoranthene, $C_{15}H_{10}$, methyl-anthracene, $C_{15}H_{12}$, retene, $C_{16}H_{12}$, chrysene, $C_{18}H_{12}$, pyrene, $C_{16}H_{10}$, picene, $C_{22}H_{14}$, and carbazol, $C_{16}H_{11}N$.

2. *Liquids.* These may be neutral hydrocarbons, acids, and ethers of the same, or bases. The *neutral hydrocarbons* are benzene, C_6H_6, toluene, C_7H_8, methyl-toluene, and iso-xylene, C_8H_{10}, pseudocumene, and mesitylene, C_9H_{12}, cymene, $C_{10}H_{14}$. The *acid constituents* are phenol, C_6H_6O, orthocresol, paracresol, and metacresol, C_7H_8O, phlorol, $C_8H_{10}O$, rosolic acid, $C_{20}H_{16}O_3$, pyrocatechin, $C_6H_6O_2$, and creosote, consisting of the methyl ethers of pyrocatechin and its homologues, $C_7H_8O_2$, $C_8H_{10}O_2$, and $C_9H_{12}O_2$. There are also present, probably in combination with the ammonia of the ammoniacal liquor, acetic, butyric, carbonic, hydrocyanic, sulphocyanic, and hydrosulphuric acids. The *bases* are ammonia, NH_3, methylamine, $CH_3.NH_2$, ethylamine, $C_2H_5.NH_2$, phenylamine, $C_6H_5.NH_2$, pyridine, C_5H_5N, picoline, C_6H_8N, lutidine, C_7H_9N, collidine, $C_8H_{11}N$, leucoline, C_9H_7N, iridoline, $C_{10}H_9N$, cryptidine, $C_{11}H_{11}N$, acridine, $C_{12}H_9N$, coridine, $C_{10}H_{15}N$, rubidine, $C_{11}H_{17}N$, and viridine, $C_{12}H_{19}N$.

3. *Gases.* (1) *Illuminating gases.* Acetylene, C_2H_2, ethylene, C_2H_4, propylene, C_3H_6, butylene, C_4H_8, allylene, C_3H_4, crotonylene, C_4H_6, terene, C_5H_8, and vapors of benzene, C_6H_6, styrolene, C_8H_8, naphtalin, $C_{10}H_8$, methyl-naphtalin, $C_{11}H_{10}$, fluorene, $C_{13}H_{10}$, fluoranthene, $C_{15}H_{10}$, hexane, C_6H_{14}, heptane, C_7H_{16}, and octane, C_8H_{18}.

(2) *Heating and diluting gases.* Hydrogen, H_2, marsh-gas (methane), CH_4, carbon monoxide, CO.

(3) *Impurities.* Carbon dioxide, CO_2, ammonia, NH_3, cyanogen, $(CN)_2$, methyl cyanide, CH_3CN, sulphocyanic acid, CN,SH, hydrogen sulphide, H_2S, carbon disulphide, CS_2, carbon oxysulphide, COS, and nitrogen, N_2.

COBALT. (Co. 58·6.) This not very abundant metal is usually found associated with arsenic, and is rarely used in its pure condition in medicine or pharmacy. It occurs as *smaltine* or *tin-white cobalt*, *cobalt glance*, or *sulpharsenate; cobalt bloom*, *erythrine*, or *arsenate; earthy cobalt* or *wad*, a mixture of cobaltous oxide and black manganese oxide, and *spiess cobalt*, $(Co,Ni,Fe)As_2$.

Spiess cobalt is frequently employed as the source of cobalt salts, and the substance called in commerce *zaffre* is an impure cobalt arsenate, made by simply roasting the crude cobalt ores or calcining them, with access of air, and is used to give a blue color to glass, enamels, and pottery glaze. The native ore is frequently found in commerce under the name of *fly-stone*, and is used for poisoning flies, by roughly grinding it and putting a small quantity in a saucer with sweetened water. *Smalt* is the common name used for glass colored by fusing with oxide of cobalt, producing a blue pigment, for coloring glass, etc. The soluble salts of cobalt, particularly the *chloride* and *sulphocyanate*, have been used to impregnate paper, etc., giving it ordinarily a pink tint, indicative of the presence of moisture, while on elevation of temperature and drying the color changes to blue. Advantage has been taken of this fact to produce the so-called *barometer paper*.

COBALT BLUE. This beautiful pigment is a compound of cobalt oxide and alumina, obtained by precipitating the mixed solution of a salt of alumina and of cobalt by means of an alkali, and washing, drying, and strongly calcining the precipitate. (Berzelius.) The cobalt blue of Thénard is made by heating together the hydrated cobalt subphosphate and alumina hydrate. It is used in painting. A cobalt oxide, prepared by precipitating the chloride with potassa, has been employed in *rheumatism*. It is emetic in the dose of 10 or 20 grains (0·647 or 1·3 Gm.). The salts of the metal are irritant poisons.

COBWEB. *Spiders' Web. Tela Araneæ.* Spiders' webs were formerly much used in *headache*, *hectic fever*, *asthma*, *hysteria*, and *nervous irritation*, but probably acted solely through the imagination. Dose, from ten to twenty grains *pro re nata*. (See *Lancet*, 1867.) Spiders' web is useful as a styptic, especially after extraction of teeth, the socket being stuffed full of the web.

COCCULUS. *Cocculus Indicus. Coque du Levant*, Fr. *Kokkelskörner*, *Fischkörner*, G. *Indian Berries. Fish Berries.—Menispermum Cocculus.* Linn.—*Anamirta Cocculus.* Wight. and Arn.—*Cocculus suberosus.* D. C. (Now *Anamirta paniculata.* Colebr.) (Nat. ord. Menispermaceæ.) This is a climbing shrub, with a suberose or corky bark; having thick, coriaceous, smooth, shining, roundish or cordate leaves, sometimes truncate at the base, and the flowers in lateral compound racemes. It is a native of the Malabar Coast, and of Eastern Insular and Continental India. By Roxburgh it was proved to be one source of Cocculus, which is, however, probably derived also from other plants, notably from the *Cocculus plukenetii*, D. C. (now *Pachygone ovata*, Miers.), of Malabar, and *C. lacunosus*, D. C. (now *Anamirta paniculata*, Colebr.), of Celebes and the Moluccas. It was known to the Arabian physicians, and was imported into Europe from the Levant, from which circumstance it was called *Cocculus levanticus*. It is now brought exclusively from the East Indies.

Properties, etc. Cocculus indicus, as found in the shops, is roundish, somewhat kidney-shaped, about as large as a pea; having a thin, dry, blackish, wrinkled exterior coat, within which is a ligneous bivalvular shell, enclosing a whitish, oily, very bitter kernel. It is without smell, but has an intensely and permanently bitter taste. It bears some resemblance to the bayberry, but is not quite so large, and may be distinguished by the fact that in the Cocculus indicus the kernel never wholly fills the shell. When the fruit is kept long, the shell is sometimes almost empty. The Edinburgh College directed that "the kernels should fill at least two-thirds of the fruit." M. Boullay discovered in the kernel *picrotoxin*.

A *tincture of Cocculus indicus* is sometimes used, made by macerating the ground fruit in diluted alcohol two weeks, in the proportion of four ounces in a pint. For Procter's formula for preparing a fluid extract, see *U. S. D.*, 17th ed., or *A. J. P.*, 1863.

Cocculus indicus is used in India and elsewhere to stupefy fishes. Its powder, mixed with oil, is locally employed in the East Indies in *obstinate cutaneous affections*. An ointment of it has been used in *tinea capitis*, and to destroy vermin in the hair. Death in a child six years old, preceded by tetanic spasms and extremely contracted pupil, resulted from the application of a strong tincture of the fruit to the scalp. (*Med. Exam.*, N. S., viii. 227.) It should be used with great caution when the surface is abraded. For cases of poisoning, see Sozinsky, *Phila. Med. News*, Nov. 8, 1886; Mitchell, *Therapeutics*, Philadelphia, 1850; T. F. Haynes, *Phila. Med. Times*, vol. xiv. 748. Moderate doses produce vertigo, weakness, and headache; after large doses there are violent headache, vomiting, and furious epileptiform convulsions. (See *Picrotoxinum*, PART I.)

COCHLEARIA OFFICINALIS. L. *Common Scurvy-grass. Herba Cochleariæ*, P. G. *Herbe au Scorbut*, Fr. *Löffelkraut*, G. *Spoonwort.* This is an annual or biennial cruciferous plant, sending up early in the spring a tuft of radical leaves, which are heart-shaped, roundish, of a deep shining green color, and supported on long footstalks. The leaves of the stem are alternate, oblong, somewhat sinuate, the lower petiolate, the upper sessile. The stem is erect, branched, angular, six or eight inches high, and bears, at the extremity of the branches, numerous white cruciform peduncled flowers in thick clusters. The fruit is a roundish two-celled pod, containing numerous seeds. The whole plant is smooth and succulent. It is a native of the northern countries of Europe as well as the United States. The whole herb is active. It has, when fresh, a pungent, unpleasant odor if bruised, and a warm,

acrid, bitter taste. These properties are lost by drying. They are imparted to water and alcohol by maceration, are retained by the expressed juice, and probably depend on a peculiar volatile oil, which is separable in very small quantity by distillation with water, and is probably produced by reaction between a fixed principle in the plant and water, under the influence of myrosin acting as a ferment. (*Chem. Centralb.*, 1856, 124.) The oil was at first supposed to be identical with the oil of mustard, and, later, Geiseler gave its formula $(C_3H_5)_2CS$. (See *A. J. P.*, 1859, 416.) The boiling point, according to A. W. Hofmann, is about 160° C. (320° F.); while that of mustard oil is 147° C. (296·6° F.). (*Chem. News*, 1869, 286.) According to Hofmann, the oil is a mustard oil of the butylic series, having the formula $C_5H_9NS = C_4H_9.CSN$. Hofmann has made it synthetically.

Common scurvy-grass is gently stimulant, aperient, and diuretic. It is highly celebrated as a remedy in *scurvy*, and has been recommended in *chronic rheumatism*. The fresh plant may be eaten as a salad, or used in the form of infusion in water or wine; the expressed juice has also been used.

COCILLANA BARK. The bark of a number of species of Guarea (nat. ord. Meliaceæ) has in former times attracted attention on account of its asserted purgative and emetic properties. A species related to *Guarea trichiloides*, L., is supposed to yield cocillana. (*A. J. P.*, 1890, 178; *Bull. Pharm.*, 1893, 350.) The bark of this large Bolivian tree, which was discovered by Prof. Rusby, is believed by him (*T. G.*, 1888) to contain an alkaloid; but by Dr. John W. Eckfeldt (*Med. Bull.*, 1891) its active principle is thought to be a glucoside. In doses of from twenty to fifty grains (1·29–3·2 Gm.) the bark causes vomiting, with prostration and some purging; also, it is said, much sneezing, dull frontal headache, and discharge from the nasal mucous membrane. The therapeutic action of the drug resembles that of ipecacuanha, although as an expectorant it is somewhat more stimulant. (See *N. Y. Med. Journ.*, Dec. 1889, and April, 1890.) It has been used in *acute* and *subacute bronchitis*, *bronchial pneumonia*, *phthisis*, etc., with asserted success. Dose of the fluid extract, from ten to twenty-five drops (0·49–1·23 C.c.) every three or four hours.

COCO-NUT OIL. *Cocoa-nut Oil. Cocoa-nut Butter. Oleum Cocos*, P. G. *Oleum Cocois. Beurre de Coco*, Fr. *Kokosnussöl*, G. This must not be confounded with the fixed oil of the chocolate nut, which is often called *cocoa-butter*. (See PART I.) The substance here considered is the fixed oil of the coco-nut, which is the fruit of a species of palm, *Cocos nucifera*, L., universally known as the *coco-nut tree*, or *cocoa-nut tree*. The oil is obtained either by expression or decoction. It is of a fine white color, of the consistence of lard at ordinary temperatures, becoming solid, like suet, between 40° F. and 50° F., and liquid at about 80° F., of a bland taste, and a peculiar, not disagreeable odor. It is readily dissolved by alcohol. It contains large quantities of the glycerides of myristic and lauric acids, with smaller quantities of the glycerides of palmitic and oleic acids. It has also been found to contain several volatile acids, as caproic, caprylic, and capric acids. (Lewkowitsch, *Chemical Analyses of Oils, Fats, and Waxes*, 2d ed., 1898, 538.)

The oil has been used for various purposes in medicine and pharmacy. It has been employed as a substitute for cod-liver oil, especially in the form of a proprietary preparation, *coco-olein*. In Germany it has been used in pharmacy, to a considerable extent, as a substitute for lard, to which, according to Pettenkofer, it is preferable on account of its less tendency to rancidity, its more ready absorption when rubbed on the surface of the body, and its less liability to produce chemical changes in the substances with which it is associated. Thus, the ointment of potassium iodide, when it is made with lard, becomes yellow in a few days; while, if made with coco-nut oil, it remains unchanged for two months or more. Vegetable substances also keep better in ointment prepared with this oil than with lard. Besides, it takes up one-third more water, which is a useful quality when it is desirable to apply saline solutions externally. To prepare it for use, nothing more is ordinarily necessary than to melt it at a moderate heat, and strain it through linen. If colored, it may be digested with powdered animal charcoal, and subsequently filtered through paper. (*A. J. P.*, xxix. 331.) Coco-nut oil is employed in the manufacture of soap, particularly of the transparent varieties, and the so-called "marine soaps" and filled soaps; it is also largely used for giving firmness to the ordinary soap; this property also permits of the addition of a large quantity of water to the soap. Unfortunately, coco-nut oil soap is very apt to contain free caprylic acid; and the persistent rancid odor, resembling that of infants' vomit, left upon the skin after washing with its soap is an effectual bar to its very extended use. The exportations of coco-nut oil from Ceylon amount to 15,000 tons annually, from British India to 4000 to 6000 tons, and from the Dutch Indies to 1300 tons per annum. Besides the oil itself, the dried pulp of the coco-nut is sent to European markets in large amounts under the name of *copra*. The export of copra from Ceylon amounts to 5000 tons annually, from Tahiti to 4000 tons, from Samoa to 3000 tons, and from Singapore to 4000 tons.

According to Dr. Parisi, the endocarp or meat of the coco-nut is a powerful tænicide. The patient should drink the milk and then eat the flesh of the nut. The coco-nut is said to be largely used in India as a vermifuge, and the matter appears to have practical importance.

CŒLOCLINE POLYCARPA. A. D. C. *Unona polycarpa.* De Cand. (Now *Xylopia polycarpa*, Oliver.) *Berberin Tree. Yellow-dye Tree of Soudan.* This small tree, of the nat. ord. Anonaceæ, growing in Soudan, Sierra Leone, and certain parts of Western Africa, was described by Dr. William F. Daniell. (*P. J. Tr.*, Feb. 1857.) When wounded, the tree exudes a juice which produces a yellow stain upon linen that cannot be washed out. The epidermis of the bark is greenish gray, interrupted by occasional blackish patches; the inner layers are of a golden yellow, and very fibrous, so that they can be separated in ribbon-like bands. The bark is moderately but disagreeably bitter, and stains the saliva yellow. Water extracts its color and bitterness. Dr. Stenhouse has ascertained that it contains *berberine*. The bark is much used in Africa for dyeing yellow. In Sierra Leone it is employed topically, in powder or decoction, for *obstinate ulcers*.

COIX LACRYMA. L. (Now *C. Lacryma-Jobi.* L.) *Job's Tears.* A graminaceous plant, whose very hard fruit is used as beads.

COLCHICINE. $C_{22}H_{25}NO_6$. Salts of this alkaloid have been used to some extent in the treatment of rheumatic affections. *Colchicine tannate* is a yellow powder, containing 38 per cent. of colchicine, which may be given in doses of from 0·001 to 0·004 Gm. *Colchicinæ salicylas, Colchisal, Colchicine salicylate,* is a yellow amorphous powder, soluble in water, alcohol, and ether. It has been alleged to be of especial value in the treatment of *rheumatism* and *gout,* as combining the activities of its constituents. It is plain, however, that the amount of salicylic acid in it is too small to influence the system. The pure colchicine salicylate is scarcely a commercial article; the liquid preparation sold under that name by French manufacturers is of unknown constitution. Dose of pure salicylate, from $\frac{1}{130}$ to $\frac{1}{82}$ of a grain (0·0005–0·002 Gm.) three or four times a day.

COLLINSONIA CANADENSIS. L. *Horse-weed. Horse-balm. Richweed. Heal-all. Stone-root. Knot-root. Knob-weed. Guérit tout, Baume de Cheval,* Fr. *Collinsonie,* G. An indigenous labiate plant, with a perennial, knotty root, and an herbaceous simple stem, about two feet high, furnished with two or three pairs of broad cordate-ovate, smooth leaves, and terminating in a panicle of yellow flowers in branched racemes. The flowers are diandrous and monogynous, with a labiate calyx and corolla, the latter of which has the lower lip fringed. The plant grows in woods from Canada to the Carolinas, and flowers from July to September. The whole plant has a strong disagreeable odor, and a warm pungent taste. C. N. Lochman (*A. J. P.,* 1885, 228) found in the root a resin, tannin, starch, mucilage, and wax; in the leaves resin, tannin, wax, and volatile oil. It is considered tonic, astringent, diaphoretic, and diuretic; and the root, in substance, is said to irritate the stomach, and produce vomiting, even in small doses. A decoction of the fresh root has been used in *catarrh of the bladder, leucorrhœa, gravel, dropsy,* and other complaints; and the leaves are applied by the country-people, as cataplasm or fomentation, to wounds and bruises, and in internal abdominal pains.

COLUBRINA. *Mabee bark,* yielded by the *Colubrina reclinata,* Brongn. (now *Ceanothus reclinatus,* L'Herit.), of South America, has been analyzed by Messrs. Elborne and Wilson, who find in it a glucoside. It is used in the West Indies as a stomachic. (See *P. J. Tr.,* April 11, 1885.)

COLUTEA ARBORESCENS. L. *Bladder Senna. Baguenaudier, Séné Indigène,* Fr. *Falsche Senna,* G. A leguminous shrub growing spontaneously in the southern and eastern parts of Europe, and cultivated in gardens as an ornamental plant. Its leaves are pinnate, consisting of from three to five pairs of leaflets, with an odd one at the end. The leaflets are obovate, slightly emarginate, smooth, and of a deep green color on the upper surface, grayish green and somewhat pubescent beneath. The flowers are yellow, and the fruit vesicular, whence the plant derived its vulgar name. The leaflets are purgative, and in some parts of Europe are used as a substitute for senna, which is said to be sometimes adulterated with them. Barbey (*P. J. Tr.,* 1895, 261) isolated *coluteic acid,* which occurs in white crystals, insoluble in water, soluble in alcohol, chloroform, and carbon disulphide. Bladder senna is comparatively very feeble. It is administered in infusion or decoction, of which the dose is about half a pint, containing the virtues of from one to three ounces of the leaves.

COLZA OIL. This is an oil expressed from the seed of the *Brassica campestris,* L., or *field cabbage,* a cruciferous plant which grows wild through the greater part of Europe, and is largely cultivated in France and Germany for the sake of the oil obtained by expression from its seeds. Colza oil is used in Europe as a burning oil, as a lubricating oil, and, after purification by heating with starch, as a table oil. The raw oil has a sp. gr. of 0·915, and the refined oil 0·9136. Chilled to —4° C., stearin separates out, and at —6° C. it becomes a yellowish buttery mass. The oil contains the glycerides of stearic, *erucic* (or *brassic acid,* $C_{22}H_{42}O_2$), and an oleic acid differing in some respects from ordinary oleic acid. It also contains a small amount of some sulphur compound not as yet investigated. The total consumption of rape and colza oil in Europe is estimated at from 280,000 to 300,000 tons per annum. For analysis of commercial samples, see *Chem. and Drug.,* 1894, 140.

COMMELINA. Under the name of *Yerba del Pollo,* the *Commelina tuberosa,* Linn., is said to be very largely used in Mexico in the treatment of *internal hemorrhage,* especially from the womb. From thirty to sixty grains (1·9–3·8 Gm.) of the extract may be taken in the course of one day. (See *A. J. P.,* 1897, 290.) The North American species, *Commelina communis,* L., has also had hæmostatic properties attributed to it. For chemical and microscopical study, see *A. J. P.,* July, 1898.

COMPTONIA ASPLENIFOLIA. Gaertn. (Now C. *peregrina.* (L.) Coulter.) *Sweet Fern. Ferngale. Meadow-fern.* (Nat. ord. Myricaceæ.) A shrubby indigenous plant, named from the resemblance of its leaves to the spleenwort fern. It grows in thin sandy or stony woods, from Nova Scotia to North Carolina and Michigan. All parts of it possess a resinous spicy odor. Mr. R. T. Chiles has found in it tannic and gallic acids, volatile oil, extractive, gum, resin, and a substance resembling saponin. (*A. J. P.,* xlv. 306.) H. K. Bowman found it to contain 8·20 per cent. of tannin. (*A. J. P.,* 1869, 193.) It is said to be tonic and astringent; its decoction is used in *diarrhœa.*

CONDURANGO. *Cundurango. Cortex Condurango,* P.G. This drug some years ago attracted a great deal of attention as a reputed remedy in *cancerous disease,* but further experience has demonstrated its uselessness. It appears, however, to be used largely in South America as an alterative in *chronic syphilis,* has been recognized by the German Pharmacopœia, and merits a brief notice here. According to an official investigation (*A Report on the Origin and Therapeutic Properties of Cundurango.* By Dr. Ruschenberger, Washington, 1873) made by Passed Assistant Surgeon Jos. G. Ayers, U. S. N., there are at least ten different plants known in the republic of Colombia as condurango. The variety which has been used in *cancer,* and which may be considered as genuine condurango, is the *condurango blanco,* the product of an asclepiadaceous vine from ten to thirty feet in length and from one to two inches in diameter. The plant, which has been named *Pseusmagenuetus equatorium,* is the *Gonolobus cundurango,* Triana, and now the *Mars-*

denia cundurango, Rchb. fil. The bark is prepared by pounding the stem with a mallet, to separate it, and then drying it in the sun. It is from one-sixteenth to one-sixth of an inch thick, with a smooth external surface of an ash-gray color, diversified with greenish and blackish lichens. When dried on the stem the bark has a darker color. Dr. Thomas Antisell (*A. J. P.*, xliii. 289) found in it tannin, extractive matter, and a yellow resin, to which he attributes whatever of virtue the plant may contain. Dr. Vulpius (*P. J. Tr.*, 1066) has found in it *condurangin*, a substance very closely allied to vincetoxin of Tanret, and, like it, converted by warming when in concentrated solution into a tolerably stiff jelly. For Barthe's method of isolating it, see *A. J. P.*, 1892, 640. Carrara (*A. J. P.*, 1892) obtained from the so-called condurangin of commerce two principles: one insoluble in water, soluble in benzene, a light, almost white, powder, melting at from 60°–61° C., and of the composition $C_{20}H_{32}O_6$; the other soluble in water, of yellowish color, melting at 134° C., and of the formula $C_{18}H_{28}O_7$. Both compounds are decomposed by acids, yielding a brown pitchy substance, insoluble in water. Condurango blanco seems to have little or no positive physiological action. Gianuzzi and Bufalini, indeed, affirm that it is a convulsant, like strychnine, but Dr. Lauder Brunton has shown (*Journ. of Physiol.*, vol. v.) that it has no action upon frogs or rabbits unless the unfiltered solution be injected into the jugular vein, and it would seem probable that the convulsions seen by the Italian observers were the result of cerebral embolisms. Nevertheless, Prof. Kobert found condurangin to be a violent poison, causing convulsions followed by paralysis; he believes it to be a mixture of several principles. (*Schmidt's Jahrb.*, 1889, No. 9.) Dr. H. Chiriboga states that two or three drachms of it taken by himself in the form of decoction produced considerable activity of the circulation, copious diaphoresis, increased secretion of urine, and even some vertigo and disturbance of vision. Under the name of *Guayaquil condurango* a drug has appeared in the European markets composed of pieces of bark and fragments of woody branches, believed to be derived from an asclepiadaceous plant closely related to the genus Gonolobus. *Mexican condurango* is composed of split stems or thin adherent bark, and is thought to be yielded by an Aristolochia. For full description, see *Pharm. Rundschau*, May, 1888.

CONIOSELINUM CANADENSE. H. G. *Selinum Canadense.* Michx. (Now *Conioselinum Chinense.* (L.) B. S. P.) *Hemlock Parsley.* This plant grows in swamps in the northern parts of the United States and in Canada. (See *Edin. Med. Journ.*, 1865, 1106.) It is occasionally used in *dysentery.*

CONNARUS AFRICANUS. G. F. W. Mey. (Now *C. guianensis.* Lamb.) *Seribéle.* The seeds and root bark of this plant (nat. ord. Connaraceæ), from French Guinea, are used as tænifuges; two ounces of the seeds in decoction, without straining. (Maclaud, *P. J. Tr.*, 1896, 243.)

CONTRAYERVA. *Contrayerva. Contrayerve*, Fr. *Bezoarwurzel, Giftwurzel*, G. The root of *Dorstenia Contrajerva*, L., of the nat. ord. Urticaceæ, a native of Mexico, the West Indies, and Peru. According to Pereira and Dr. Martius, the contrayerva of the shops is the product of *D. Brasiliensis*, Lam., and is brought from Brazil. The term contrayerba, in the language of the Spanish Americans, signifies *counterpoison* or *antidote*, and was applied to this root under the impression that it had the property of counteracting all kinds of poison. The probability is that the root sold as *contrayerva* is derived from several species of Dorstenia, among which, besides *D. Contrayerva*, two others are mentioned by Dr. Houston, *D. Houstoni*, L. (now *D. Contrajerva*, L.), and *D. Drakena*, L., the former growing near Campeachy, the latter near Vera Cruz.

The root, as found in commerce, is oblong, an inch or two in length, of varying thickness, very hard, rough, and solid, of a reddish-brown color externally, and pale within; and has numerous, long, slender, yellowish fibres attached to its inferior part. The odor is aromatic; the taste warm, slightly bitterish, and pungent. The fibres have less taste and smell than the tuberous portion. The sensible properties are extracted by alcohol and boiling water. The decoction is highly mucilaginous. The tincture reddens infusion of litmus, and lets fall a precipitate on the addition of water. Mussi (*L. Orosi*, 1894, 259) investigated this plant and found two substances, which he calls provisionally *cajapine* and *contrayerbine.* Contrayerva is a stimulant tonic and diaphoretic, and has been given in *low fevers*, *typhoid dysentery*, and *diarrhœa*, and other diseases requiring gentle stimulation. Dose, of powdered root, half a drachm (1·94 Gm.).

CONVALLARIA POLYGONATUM. Linn. (*Polygonatum uniflorum*, Gilib.; now *P. officinale*, All.) *Solomon's Seal. Sceau de Salomon, Genouillet*, Fr. *Weisswurzel, Salomon's Siegel*, G. (Nat. ord. Liliaceæ.) A perennial, herbaceous European plant, whose root is inodorous. It is said to be emetic. In former times it was used externally in *bruises*, especially those about the eyes, in *tumors*, *wounds*, and *cutaneous eruptions*, and was highly esteemed as a cosmetic. At present it is not employed. The berries and flowers are said to be acrid and poisonous. *C. multiflora*, L. (*Polygonatum multiflorum*, All.), which grows both in this country and in Europe, is analogous to the preceding in properties. (See Dr. John H. Rauch, *Inaug. Essay*, 1849.)

CONVOLVULUS PANDURATUS. L. (Now *Ipomœa pandurata* (L.), Meyer.) *Wild Potato. Man-root. Man of the Earth. Wild Jalap.* The wild potato plant has a perennial root, and a round, purplish, procumbent or climbing stem, which twines around neighboring objects, and grows sometimes twelve feet in height. The leaves, which stand alternately on long petioles, are broad, heart-shaped at the base, entire or lobed on the sides like a guitar or violin, somewhat acuminate, deep green on the upper surface, and paler beneath. The flowers are in fascicles, upon long axillary peduncles. The calyx is smooth and awnless; the corolla tubular, campanulate, very large, white at the border, but purplish red at the base. The plant is indigenous, growing throughout the United States in sandy fields and along fences, and flowering from June to August. A variety with double flowers is cultivated in the gardens for the sake of ornament. The root, which was the official part, is very large, two or three feet in length, about three inches thick, branched at the bottom, externally of a brownish-yellow color, and full of

longitudinal fissures, internally whitish and milky, and of a somewhat acrid taste. The wild potato is feebly cathartic and diuretic. (*N. Y. Journ. of Med.*, x. 375), useful in *strangury* and *calculous complaints*. Forty grains (2·59 Gm.) of the dried root are said to purge gently.

COPAL. A resinous substance, brought from the East Indies, South America, and the eastern and western coasts of Africa, but most abundantly from the first mentioned source. It is the concrete juice of different trees, and is furnished by exudation. The East India copal has been ascribed to the *Vateria Indica*, L. (nat. ord. Dipterocarpeæ), the *Elæocarpus copaliferus*, Retz. (now *Vateria acuminata*, Hayne), and the Brazilian, by Martius and Hayne, probably with reason, to different species of Hymenæa. (Nat. ord. Leguminosæ.) There are some grounds for believing that the East India copal is also the product of a Hymenæa; at least a specimen of this resin was collected by M. Perottet from the *Hymenæa verrucosa*, Hornem. (now *Trachylobium Hornemannianum*, Hayne), which he found growing in the Isle of Bourbon. This tree is a native of Madagascar, and probably of the neighboring parts of Africa; and M. Perottet was informed that the copal of India is taken thither by the Arabs of Muscat, who obtain it from the east coast of Africa. (*Journ. de Pharm.*, 3e sér., i. 406.) It is stated by James Vaughan, who was stationed as army surgeon at Aden in Arabia, that copal is taken to that port from the African coast, opposite the island of Zanzibar, where it is said to be dug up from the earth. (*Pharm. Journ.*, xii. 385.) Col. Playfair, British consul at Zanzibar, has sent to the Kew Museum specimens of the bark of a tree, with the resin *in situ*, and specimens of the collected resin, and of the fruit of the tree, which leave little doubt that the Zanzibar copal is obtained from the *Hymenæa Mozambicensis*. (*Trachylobium mossambicense*, Klotzsch.; now *T. Hornemannianum*, Hayne.) In a communication from John Kirk, dated Zanzibar, March 20, 1865, it is stated that the smooth copal exported from that region is obtained from the *Trachylobium mossambicense*, Klotzsch. (now *T. Hornemannianum*, Hayne), a small tree or bush, distinguished by its rounded head of glossy leaves, with groups of white flowers at the ends of the branches. The trunk and limbs are covered with a clear resinous exudation, portions of which, after solidifying, drop to the ground and are collected, while other portions are broken from the tree. This kind of resin is always smooth, and is exported to India. Another variety, with an indented goose-flesh surface, known in the English market as *animé*, is dug from the earth, and, though the product of forests now extinct, originated probably from the same tree. (*P. J. Tr.*, 1869, 654.) W. F. Daniell (*P. J. Tr.*, xvi. 369 and 423) has given an account of several varieties of copal produced on the coast and interior parts of Western Africa, from Sierra Leone to Angola and Benguela. Those from Sierra Leone, which are most highly valued for their superior hardness and transparency, are said by Dr. Daniell to be derived from the *Guibourtia copallifera* of Bennett (now *Copaifera Guibourtiana*, Benth.), a large leguminous tree, growing preferably in mountainous regions, and very nearly related, botanically, to the *Hymenææ* which produce copal in other regions. The drug is mostly collected, not from the tree itself, but from the beds and borders of streams, into which it is washed down, during the rains, from the hill-sides, in the soil of which it had been deposited. Copal varies in appearance and properties as procured from different sources. It is in roundish, irregular, or flattish pieces, often rough over the surface, probably from the impression of sand in its soft state, colorless, yellowish, or brownish yellow, more or less transparent, very hard, with a shining, conchoidal fracture, inodorous and tasteless, of a sp. gr. varying from 1·045 to 1·139, insoluble in alcohol, partially soluble in ether, and slightly so in oil of turpentine. Some varieties unite with alcohol, if suspended in its vapor while boiling. By heat it melts and emits gases, loses from 15 to 20 per cent. of weight, and is altered so as to become soluble in ether, alcohol, and oil of turpentine, and in this way copal varnishes are usually made. It is not a proximate principle, but consists of various resins united in different proportions. According to Unverdorben and Filhol, some five different resins can be obtained by the successive action of solvents. On the distillation of copal, an oil is obtained of the composition $C_{10}H_{16}$, boiling at from 160°–165° C., and sp. gr 0·965, together with an oxygenated oil, showing it to have arisen from the oxidation of various terpenes, $C_{10}H_{16}$. The East India or African copal is described by Mr. Schindler as of a globular form, softer and more transparent than the other varieties, with a surface always clear, and having an agreeable smell when heated. It is readily and freely dissolved by the oils of turpentine and rosemary when pure, but not by these fluids when rendered resinous by age. It is more readily fusible than the others, and makes the best varnish. The West India copal is in flat pieces, seldom weighing more than three ounces, rarely containing insects, very hard, of a rough appearance, of a yellowish color, and without smell or taste. It is much less readily dissolved by oil of turpentine than the East India variety, swells but does not dissolve in oil of rosemary, and is slightly soluble in absolute alcohol. A third kind, probably also American, is in convex or concave pieces, about a pound in weight, often containing insects and other impurities. In solubility it resembles the last-mentioned variety, in fusibility is intermediate between it and the East Indian, and is altogether inferior. (*P. J. Tr.*, 1850.) The African or Sierra Leone copal is described by Daniell as occurring "in small round tears, or irregular conical and smooth nodulated masses, seldom exceeding in size an ordinary duck egg. They are covered, to a greater or less extent, by a peculiar white efflorescence, which increases by age. Their color graduates from a pale green to a lemon or dull yellow." (*Ibid.*, xvi. 369.) Welwitsch states that this drug is mostly found in sandy soil, in the hilly districts, along the whole coast of Angola, where its prevalence coincides with that of *Adansonia digitata*, L. (Nat. ord. Malvaceæ.) It is dug from the earth, or found in spots where it has been collected by the washing of the rains, or laid bare by earth-falls; and the quantity annually collected in this region, and exported from Benguela, from 1850 to 1860, was 1,600,000 pounds. The surface, like that described by Daniell, is covered with a whitish earthy crust, sometimes exhibiting veins or net-work, probably produced by attrition in their conveyance by floods. (*A. J. P.*, 1866.)

Inhabane copal has been shown to be the product of *Copaifera Gorskiana*, Benth. (nat. ord. Leguminosæ), and seeds sent to Kew Gardens in 1886 germinated, and the plant has been widely introduced into both the East and West Indies, and into Australia. (*P. J. Tr.*, xix. 508.)

Crude and *scraped* copal are known in the market; the former of a dull opaque appearance externally, the latter much clearer and more transparent, in consequence of being deprived of its outer coat. The process of *scraping* is said to consist in the removal of the exterior portion by means of an alkaline solution, which readily dissolves copal. This resin is used chiefly in making varnishes. H. Violette states (*A. J. P.*, 1863, 140) that certain varieties of copal used for varnish, which are not naturally soluble in ether, oil of turpentine, benzin, petroleum, etc., become soluble in these menstrua, whether cold or hot, by being heated in close vessels to the temperature of from 350° to 400° F., and thus yield excellent varnishes without loss of matter; and the same resin, heated as above with one-third of linseed oil and three-fourths of oil of turpentine, gives directly a clear, limpid, slightly yellowish varnish, fit for the most delicate uses. (*Journ. de Pharm.*, 4e sér., iv. 284.) Edison found aniline oil a good solvent for copal.

COPPER, BLACK OXIDE OF. *Cuprum Oxydatum*, P. G. *Oxyde de Cuivre, Safran de Vénus*, Fr. *Kupferoxyd*, G. Cupric oxide, CuO, is obtained most conveniently by heating to redness the nitrate. This oxide, in the form of ointment, made by mixing four parts with thirty of lard, has been locally used twice a day to remove *chronic indurations of the glands*. (Hoppe, *Ann. de Thérap.*, 1855.)

COPTIS. *Goldthread. Coptide*, Fr. *Gelbe (Kleinste) Niesswurz*, G. The slender, bright yellow root of the indigenous creeping plant *Coptis trifolia* (L.), Salisb., was formerly official in the U. S. Pharmacopœia. The plant belongs to the Ranunculaceæ; the leaves, which stand on long slender footstalks, are ternate, with firm, rounded or obovate, sessile leaflets, having an acute base, a lobed and acuminately crenate margin, and a smooth veined surface. The flower-stem is slender, round, rather longer than the leaves, and surmounted by one small white flower, with a minute mucronate bract beneath it. The five or six caducous petals are oblong, concave, and white; the nectaries inversely conical, hollow, and yellow at the top. The stamens have capillary filaments and globose anthers. The carpels are from five to eight, stipitate, oblong, compressed, and support short recurved styles, with acute stigmas. The follicles, which diverge in a star-like form, are pedicelled, compressed, beaked, and contain numerous black seeds attached to the inner side. The goldthread inhabits the northern region of this continent and of Asia, and is found in Greenland and Iceland. It delights in the dark shady swamps and cold morasses of northern latitudes and alpine regions, and abounds in Canada and in the hilly districts of the Northern United States.

Dried goldthread, as brought into the market, is in loosely matted masses, consisting of the long, thread-like, orange-yellow roots, frequently interlaced, and mingled with the leaves and stems of the plant. It is without smell, and has a purely bitter taste, unattended with aroma or astringency. It imparts a bitterness and yellow color to water and alcohol, but most perfectly to the latter, with which it forms a bright yellow tincture. The infusion is precipitated by silver nitrate and lead acetate. (Bigelow.) It affords no evidence of containing either resin, gum, or tannin. The plant undoubtedly contains *berberine*, which, according to Prof. F. F. Mayer (*A. J. P.*, 1863) and Mr. E. Z. Gross (*Ibid.*, 1873), is associated with another alkaloid. Mr. Gross states that *coptine* differs from berberine in its colorless crystals, and by forming with potassium iodohydrargyrate a crystalline instead of flocculent precipitate. (See also paper by John J. Schulz, *A. J. P.*, 1884, 261.) Mr. C. W. Burr detected starch in *Coptis trifolia*. (*A. J. P.*, 1884, 31.) Goldthread is a simple tonic bitter, bearing a close resemblance to quassia in its mode of action, and applicable to all cases in which that medicine is prescribed, though, from its higher price, not likely to come into general use as a substitute. In New England it is employed as a local application in *aphthous ulcerations* of the mouth; but it probably has no other virtues in this complaint than such as are common to the simple bitters. It may be given in substance, infusion, or tincture. The dose of the powder is from ten to thirty grains, of a tincture made with an ounce of the root to a pint of diluted alcohol, one fluidrachm.

The *Coptis Teeta* of Wallich, which grows in the mountainous regions bordering on Assam, is much used as a tonic by the natives and by the Chinese. It is analogous in properties to *C. trifolia*, and is said to contain 8½ per cent. of berberine. It has been brought into use in British India. It is highly commended by Mr. Twining as a stomachic tonic. (*P. J. Tr.*, 1870, 161.) *Coptis anemonæfolia* (Lieb. and Zucc.) is said to contain berberine, and has been used in Japan in *intestinal catarrh*. (*Sei-i-Kwai*, 1892.)

CORAL. *Corail*, Fr. *Koralle*, G. The solid mesodermal calcareous skeletons of the coral polyps, *anthozoa*, were formerly used in medicine, but have passed out of vogue. Their chief constituent is calcium carbonate, colored by ferric oxide, and united with more or less animal matter.

CORALLIN. *Pœonin.* A coloring or dyeing material, derived from *rosolic acid* or *aurin* ($C_{19}H_{14}O_3$), which is itself derived from *carbolic acid* or *phenol* by the joint action of sulphuric and oxalic acids upon it. It is formed by exposing together rosolic acid and alcoholic ammonia to a heat of 149° C. (300° F.), and is considered to be an intermediate product between pararosaniline and pararosolic acid. A solid substance is thus obtained, in scales of a peony redness, with reflected green or dull yellow rays, almost insoluble in water, soluble in alcohol and the fixed oils. Dr. Ambrose Tardieu, having met with some extraordinary cases of a severe vesicular eruption upon the feet, attended with violent inflammation and swelling, and with general febrile symptoms, attributed to the wearing of red socks, found that these socks yielded nothing to water, cold or hot, feebly acidulated or alkaline, but did give up their red coloring matter to boiling alcohol of 85°. By evaporating the alcoholic solution thus made, an extract was obtained, which, on being injected in alcoholic solution into the areolar tissue of a dog, rabbit, and frog, produced death in all: in the frog in four hours, in the dog after thirty-six hours, and in the rabbit later; the two latter animals having been copiously and almost incessantly purged. An alcoholic solution of pure corallin

was then injected into animals as before, with the same result. A dog was killed by twenty centigrammes (about three grains), a rabbit by half the quantity, and a frog by five centigrammes, or less than a grain. In the dog and rabbit there was violent purgation, with intense fever and progressive prostration, and the leg of the side in which the injection had been made was very painful. After death the neighborhood of the wound was found suppurating, the stomach sound, and the intestines distended, with signs of violent inflammation of the mucous membrane; the liver presented evidences of fatty degeneration; and the lungs appeared as if dyed by the scarlet coloring matter. M. Roussin succeeded in extracting a portion of the coloring matter from the lungs and liver, and dyeing with it a skein of silk. These experiments are very interesting from a medico-legal point of view; as corallin might be readily detected in this way, if at any time, accidentally or otherwise, the cause of fatal results. Hitherto the effects on the human subject have been confined to the painful cutaneous affection, which has been so satisfactorily traced to contact of the skin with the silk fabrics dyed with it; but even in these cases there were serious constitutional symptoms, as fever, headache, giddiness, and nausea. (*Journ. de Pharm.*, 1859, 262.)

Local poisoning may be caused by aniline red as well as by corallin: the two colors may be distinguished in tissues. *Aniline red* disappears very rapidly by contact with ammonia; but the color reappears by the addition of an acid, or by the evaporation of the alkali. *Corallin red* is not dissolved by cold water, yields a slight color to boiling water, but rapidly disappears from the tissue under the action of boiling alcohol. Alkalies brighten the color without changing it; acids precipitate the coloring matter in yellow flakes. (*Ibid.*, 1869, 371.) Some observers later than Tardieu believe that pure corallin is not poisonous, and that the symptoms have been produced by arsenic or other contaminating substances. (See *Med. Times and Gaz.*, 1869, 421; *P. J. Tr.*, 2d ser., xi. 360; also *New York Med. Journ.*, 1870, 599; *N. R.*, i. 288.)

CORALLORHIZA ODONTORHIZA. (Willd.) Nutt. *Coral-root.* (Nat. ord. Orchidaceæ.) This is a parasitic leafless herb, sending up from a coral-like rhizome a simple scape or flower-stem, from six to sixteen inches high, furnished with sheaths instead of leaves, of a light brown or purplish color, and bearing small, greenish-brown flowers in a long spike. The plant grows throughout the United States east of the Mississippi. The rhizome is the part used. It is much branched and toothed, and of a brown color, and from its resemblance to coral gave name to the plant. It has a strong peculiar odor, and an astringent bitterish taste. It is much valued by the "eclectics" as an energetic diaphoretic, destitute of general stimulant properties. It is given in *fevers;* dose of powder, thirty grains (1·94 Gm.) every two hours.

CORDOL. *Salol Tribromide*, $C_6H_4.OHCOO.C_6H_2Br_3$. A white, tasteless, and odorless powder, insoluble in water, ether, and alcohol, freely soluble in chloroform and glacial acetic acid. *Cordyl* or *acetyl tribromsalol* is insoluble in water, and occurs in the form of fine white needles. *Cordeine* or *methyl tribromsalol* occurs in small white crystals, which are insoluble in water, but soluble in alcohol and chloroform. Cordol, cordyl, and cordeine are said to be hypnotics which have the advantage of being almost tasteless. The dose of either is from eight to fifteen grains (0·5–1 Gm.).

CORIARIA MYRTIFOLIA. L. *Currier's Sumach. Redoul, Sumach des Corroyeurs*, Fr. *Gerberstrauch*, G. (Nat. ord. Coriarieæ.) This is a shrub growing wild in Southern Europe, which is sometimes cultivated in gardens on account of its handsome foliage. The leaves, which are used for dyeing black, were at one time employed to a considerable extent in France in the adulteration of senna. The fruit, resembling berries in form, are black, and about the size of a pea. Both these and the leaves are poisonous in large doses, and several instances of death are on record from eating the fruit. (Mérat and De Lens.) M. Riban has discovered in the fruit *coriamyrtin*. This is in the form of white crystals, inodorous, excessively bitter, and extremely poisonous. It fuses at 220° C., and crystallizes again on cooling. It is but slightly soluble in water, hot or cold, but freely so in alcohol, ether, chloroform, and benzol. Its composition is represented by the formula $C_{30}H_{36}O_{10}$. It ranks with the glucosides, as when boiled with diluted hydrochloric acid at least three decomposition products are formed, of which one separates in yellow flocks, while the solution reduces alkaline copper solutions. About three grains caused in a dog vomiting, severe convulsions, and death in an hour and a quarter. M. Riban obtained it by treating the juice of the fresh or an infusion of the dried fruit and leaves at first with lead acetate, then with hydrogen sulphide to throw down the lead, concentrating the filtered liquid to a syrupy consistence, and agitating this with ether, which extracted the poison, and yielded it on evaporation. (*Journ. de Pharm.*, 1864, 487.)

Toot-poison. Tu-tu. In New Zealand a poisonous plant, known as the *toot-plant*, has proved very destructive to the domestic animals. W. Lauder Lindsay found it to be the *Coriaria ruscifolia* of Linnæus (*C. sarmentosa*, Forst.?), and in its action on the system to be an irritant narcotic. For an elaborate account of the *toot-plant*, and its poisonous effects, see *Brit. and For. Med.-Chir. Rev.* (1865, 153, and 1868, 465). From these it appears that more than one species of Coriaria inhabit New Zealand, *C. thymifolia*, Humb. et Bonpl., and *C. angustissima*, Hook. f., besides the *ruscifolia;* though Lindsay appears to think that the two former may be merely varieties of the third. It is not only cattle that are poisoned by the plant, but not infrequently also children, and occasionally even an adult. The cattle are probably, in general, poisoned by eating the young shoots. It has been conjectured that the same narcotic principle found in *C. myrtifolia* (*coriamyrtin*) is that which renders the New Zealand species poisonous. W. S. Key has found an oil in it, to which he attributes the poisonous qualities. (*Chem. News*, 1870, xxii. 315.) It is affirmed by T. H. Hustwick (*P. J. Tr.*, 22, vol. xv.) that goats are not poisoned by the tu-tu, and have even been used to eradicate the plant by browsing; also that the berries when ripe are not only not poisonous to man, but, if care is taken to reject the seeds, are a grateful and refreshing fruit. The prominent symptoms of the poisoning in man are giddiness, stupor, and coma, with or without delirium or convulsions. Occasionally the delirium

resembles that of alcoholic intoxication, in other instances approaches that of acute mania, and is attended with violent muscular action. Loss of memory is characteristic of the convalescence.

CORK. *Suber*, Lat. *Liége*, Fr. The great use made of this substance in pharmacy and the arts justifies a brief notice of it. Though in general ascribed exclusively to the *Quercus Suber*, L. (now *Q. Ilex*, L.) (nat. ord. Cupuliferæ), a large oak growing in Spain, the south of France, north of Italy, Algeria, and some of the Mediterranean islands, it is said by M. Casimir de Candolle to be obtained also for commercial purposes from another species, the *Q. occidentalis*, F. Gay, growing in the southwest of France and in Portugal. It consists of the exterior layers of the bark beneath the epidermis, which acquire in these species an extraordinary development, becoming thick, and of that peculiar spongy consistence which characterizes cork. The tree begins to yield cork when fifteen or sixteen years old, and every six or eight years furnishes a fresh supply, even for a century and a half, before it perishes; that interval of time being required for the renewal of the suberose layers by the living portions of the bark beneath. There are four constituent layers of the bark: the epidermis, within this the cork, next the cellular envelope, and lastly the liber which lies upon the wood. Each of these increases year by year; but the cork thus naturally produced is not valued. The commercial product is obtained by an artificial process. The exterior layers are removed, and the liber exposed. In the interior of this, at a variable distance from the surface, a layer of the proper cork is now formed, apparently by a change in the substance of the liber, the outer portions of which perish, while annually a new layer is added to the cork already existing, until it acquires a thickness which will justify its removal. Incisions are made in such a way that the cork is removed in large concave plates, which are then flattened under pressure, and dried.

In selecting cork for use, those parts should be preferred which are soft and of uniform consistence; and in the choice of the larger plates those should be selected which are thick, flexible, elastic, finely porous, and of a reddish color. Boiling hot alcohol extracts from rasped cork tissue some 10 per cent. of soluble principles. From the hot alcohol solution a substance crystallizes which was first noticed by Chevreul under the name of *cerin*. According to Kugler (*Dissertation on Suberin*, Halle, 1884), besides cellulose and lignin, cork contains two constituents, *cerin*, to which he gives the formula $C_{20}H_{32}O$, and *suberin*, which is a fat, and contains stearic acid and *phellonic acid*, $C_{22}H_{42}O_3$. This constituent, suberin, prevents the penetration of liquid into the cork, and is only completely extracted by alcoholic potash. When treated with nitric acid, cork yields a peculiar acid, which has been denominated *suberic acid*. This is a dibasic acid homologous with oxalic acid, and has the formula $C_8H_{14}O_4$. It is formed by the oxidation of many other substances, such as the oils from linseed, castor bean, cocoa-nut, and almond, spermaceti, etc.

M. Stanislaus Martin has called attention in France to the use of refuse corks in Paris, where they are collected by the scavengers, and sold to persons whose business it is to revive them; recutting such as are of unsuitable shape, filling up the vacuities with mastic, and covering them over with some powder which may give them a fresh and proper appearance. In consequence of the high price of cork, those which are thus prepared over again are said to be used in the bottling of beverages. Corks are sometimes bleached with sulphurous acid, and the odor of hydrogen sulphide has been noticed in prescriptions which have been compounded, when such corks have been used in the dispensing bottle. (*P. J. Tr.*, 1881, 1080.) Mohr has found that old corks may be regenerated by allowing them to soak for twenty-four hours in hot water, washing well several times, allowing to stand for a few hours in a mixture of one part of hydrochloric acid and fifteen parts of hot water, and finally washing well in pure water. (See also *A. J. P.*, 1875, 467.) It is easy to conceive that a cork at one time used to enclose arsenical or other deadly solution may become saturated with the poison, and afterwards impart enough of it to another liquid, if not to produce dangerous effects on the health, at least to give to tests evidence of its presence, and thus lead to serious suspicions. No cork, therefore, which has been used in a bottle containing a poisonous substance should be employed a second time.

CORNUS. *Dogwood. Ecorce de Cornouiller à grandes Fleurs*, Fr. *Grossblüthige Cornelrinde*, G. Under the name of cornus, the U. S. Pharmacopœia formerly recognized the bark of the root of the *Cornus florida*, L. (Nat. ord. Cornaceæ.) This is the only American species of the genus which attains the size of a tree, reaching at times the height of thirty-five feet. It is especially characterized by its greenish flowers, which are collected in a head or close cluster, and surrounded by a large, showy, four-leaved, corolla-like, white involucre; and by its bright red fruit. These flower-clusters are extraordinarily showy in the months of May and June, and are commonly spoken of as "flowers." The fruit, an oval drupe of a vivid glossy redness, usually ripens in September.

The bark of two other indigenous dogwoods is sometimes substituted for that of *C. florida*, L. Each of these is a shrub with opposite leaves, the flowers in flat spreading cymes, and the fruit globular and blue. *C. circinata*, L'Her., is further distinguished by its branches being greenish and warty; its leaves round-oval, abruptly pointed, and woolly underneath. *C. sericea*, L. (now *C. amomum*, Mill.), is to be recognized by its purplish branches, and the branchlets, stalks, and lower surface of the elliptical pointed leaves being silky and downy.

These dogwoods are found in all portions of the United States east of the Mississippi, being most abundant in the Middle States, and finally disappearing southward and northward.

Dogwood bark was used many years ago as an antiperiodic in *intermittent fever*, but it is only a feeble, astringent tonic. Formerly from one to two ounces of the powder were given in the interval between the paroxysms of intermittent fever, and the U. S. Pharmacopœia recognized the fluid extract, and gave in the edition of 1880 the following formula for its production: "Cornus, in No. 60 powder, *one hundred grammes* [or fifty ounces av.]; Glycerin, *twenty grammes* [or seven and a half fluidounces]; Diluted Alcohol, *a sufficient quantity*, To make *one hundred cubic centimeters* [or three pints]. Mix the Glycerin with *eighty*

grammes [or forty-one fluidounces] of Diluted Alcohol. Moisten the powder with *thirty grammes* [or fifteen fluidounces] of the mixture, and pack it firmly in a cylindrical perolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterward, Diluted Alcohol, until the Cornus is exhausted. Reserve the first *eighty-five cubic centimeters* [or forty fluidounces] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluid Extract measure *one hundred cubic centimeters* [or three pints]." The dose of this fluid extract was from half a fluidrachm to a fluidrachm (1·85–3·7 C.c.).

CORNUTINII CITRAS. *Cornutine Citrate. Cornutine citrate* of commerce is a blackish-brown powder. According to Kobert, Lewitzky, Krohl, and others, the alkaloid cornutine is the active principle of ergot. For practical purposes the citrate is preferable on account of the difficulty of solution of cornutine. Lewitzky affirms that, in doses of from one-twelfth to one-sixth grain, cornutine administered by the mouth is very active and certain in its influence upon uterine contraction and in congestive and hemorrhagic *metritis*. These statements are confirmed by Thompson and Krohl. Meisel alleges that it is a powerful remedy in the treatment of *hemorrhage* and of paralytic *spermatorrhœa*. The citrate may be given hypodermically.

CORONILLA SCORPIOIDES. Koch. In 1886 (*Nancy Thesis*) Cardot announced that the *Coronilla Scorpioides*, Koch, a papilionaceous plant of South France, is an active cardiac poison. In 1889 Schlagdenhauffen and Reeb (*Revue Gén. Clin. Thérap.*, July, 1889) isolated a glucoside, *coronillin*, to which they assigned the formula $C_{11}H_{12}O_5$. It was a yellowish powder, soluble in water, acetone, and amylic alcohol; slightly soluble in chloroform and ether. Heated with diluted hydrochloric acid an amorphous resin was separated, *coronillein*. This also occurs as a yellow powder, but is not bitter to taste. It is insoluble in water, but dissolves in alcohol, acetone, and chloroform. The physiological studies by Gley, by Schlagdenhauffen and Reeb, and by Prevost, some years since, lead to the conclusion that coronillein acts upon the heart in a manner similar to digitalis, and to the practical trials of the drug as a succedaneum for digitalis. The most recent researches are those of Luigi Maramaldi (*Rev. Gén. de Thérap.*, cxxxvi.), who finds as the result of elaborate experiments that coronillin in small dose lowers the rate and increases the energy of the cardiac beats; whilst in larger doses it increases the systolic contraction up to the point of permanent ventricular spasm; these results being due to a direct influence upon the cardiac muscular fibre, which increases gradually its tonicity so that it becomes less extensible during diastole, contracts with more than the normal force, and finally fixes itself in systolic arrest. This action upon the heart is accompanied by increase in the arterial pressure, followed after a time by lowering of the pressure; which apparently is the result of failure of diastole, causing the amount of blood forced out of the heart at each systole to be insufficient to fill the arteries. The inhibitory intra-cardiac ganglia are said to be at first stimulated, afterwards paralyzed. The drug also depresses the spinal cord, and lowers the respiratory movements by an action which is believed by Maramaldi to be partly centric and partly peripheral. Death is produced by cardiac arrest. The toxic lethal dose for the frog weighing about 30 Gm. was found by Maramaldi to be from 0·0004 to 0·0005 Gm.; for the dog to be 0·0005 Gm. per kilo (1 to 2,000,000) of the animal's weight.

Locally coronillin appears to be actively irritant. In Maramaldi's experiments it failed to assert its physiological action when administered to the dog by the mouth; a result believed by the investigator to be due to its decomposition by the acid in the stomach. It is claimed for it that it is an excellent cardiac tonic, superior to digitalis in that it is very rapidly eliminated. As it has been found by various clinicians to be active in man when given by the mouth, it is probable that the comparative feebleness of human gastric juice permits of its absorption unchanged. The dose given by various clinicians has varied greatly, from three to five grains (0·194–0·324 Gm.) — Spillemann — downward. These differences probably depend upon differences of purity of the various samples used; of the commercial coronillin the dose is commonly stated at present to be one and one-half grains from four to six times a day, but it must be noted that Schlagdenhauffen affirms that three-fourths of a grain is a toxic dose. *Coronilla varia* of Europe also probably contains coronillin. (V. Poulet, *Bull. Gén. Thérap.*, 1891.)

CORTEX CARYOPHYLLATA. *Cassia Caryophyllata. Clove Bark.* These names have been given to a bark, brought from the West Indies, and derived from a tree belonging to the family of Myrtaceæ, supposed to be the *Myrtus acris* of Swartz (now *Pimenta acris*, Kostel). It is usually in cylinders from one to two feet long by an inch in diameter, composed of numerous separate pieces rolled around one another, having a dark brown color, a pungent taste, and an odor similar to that of cloves. It is sometimes in fragments, of a similar color, taste, and smell, but softer and lighter, and supposed to be derived from older branches. A similar bark is said to be derived from the *Myrtus caryophyllata* of Linn. (now *Eugenia caryophyllæa*, Wight), which grows in Ceylon. This clove bark has aromatic properties not unlike those of the spice from which it derived its name; but it is much inferior, and is not used in this country. Some authors have confounded with it a different bark, produced in the Moluccas, and known by the Indian name of culilawan. (See *Culilawan.*) For description of a false clove bark, see *A. J. P.*, vol. xv.

CORYDALIS FORMOSA. Pursh. *Dicentra canadensis*, Walp.; *Bicuculla Canadensis* (Goldie), Millsp. *Turkey Corn. Turkey Pea. Squirrel Corn.* (Nat. ord. Papaveraceæ.) This little indigenous plant, growing in the Middle and Western States, is highly esteemed by the "eclectics." The root is used. It is a small roundish tuber, having a slight peculiar smell, and a bitterish somewhat pungent and persistent taste. It is said to yield its active properties to water and alcohol. According to Mr. W. T. Wenzell (*A. J. P.*, 1855, 205), it contains an alkaloid denominated *corydaline*, fumaric

acid, bitter extractive, an acrid resin with volatile oil, a tasteless resin, brown coloring matter, starch, albumen, arabin, bassorin, cellulose, and various inorganic salts. The alkaloid was obtained by making a hydro-alcoholic tincture, distilling off the alcohol, filtering, precipitating with ammonia in slight excess, washing the precipitate, treating it with boiling alcohol, evaporating the solution to dryness, treating the residue with dilute hydrochloric acid, precipitating with ammonia, dissolving the precipitate in boiling alcohol, concentrating the tincture, and allowing it to stand. The corydaline was deposited in crystals, and was purified by repeated solution in alcohol and crystallization. The crystals, which are slender four-sided prisms, are inodorous, tasteless, insoluble in water, soluble in alcohol, ether, and chloroform, reddened by nitric acid, and capable of forming soluble salts with the acids. It appears to be identical with the alkaloid found in European species of Corydalis, whose formula, according to H. Wicke, is $C_{18}H_{19}NO_4$. (*Chemistry, P. J. Tr.*, xix. 990.)

According to Merck (*Berichte über das Jahr* 1892), there are in *Corydalis cava* four alkaloids, two of which (*corydaline* and *corycavine*) are weak bases, and two (*bulbocapnine* and *corydine*) strong bases. *Corydaline* was obtained crystallized in large prisms, fusing at 135° C., and easily soluble in alcohol and ether. *Corycavine* is difficultly soluble in all solvents, crystallizes in small matted needles, and fuses at 218° C. with partial decomposition. *Bulbocapnine* is a crystallizable base, melting at 199° C., and soluble in excess of caustic potash. This alkaloid is the one present in largest amount, and was first called corydaline; but Merck accepts the name bulbocapnine, proposed for it by Freund and Josephy. (*Ber. Chem. Ges.*, 25, 2411.) *Corydine* is obtained from the mother-liquors of the bulbocapnine, and is also a strong base. It is insoluble in water, very readily soluble in alcohol and ether, but cannot be obtained in crystallized form. The alkaloids of *Corydalis nobilis*, Pers., have been studied by Birsmann. (*A. J. P.*, 1893, 135.) Benzene extracts an amorphous white base of the composition $C_{21}H_{21}NO_6$, resembling the amorphous base (corydine?) of *C. cava*. On making the mother-liquor alkaline, a brown resinous mass is thrown down, from which benzene separates a base crystallizing from boiling water, with the formula $C_{22}H_{25}NO_5$, to which he gives the name *corydalnobiline*. Several other alkaloids were obtained, and indications of hydroberberine and berberine.

The root of *C. formosa*, Pursh, is supposed to be tonic, diuretic, and alterative, and is given in *syphilitic*, *scrofulous*, and *cutaneous affections*, in the dose of from ten to thirty grains. It is also used in the form of tincture and decoction. The "eclectics" use a preparation which they call *corydalin* or *corydalia*, made by precipitating a tincture of the root with water, in the dose of half a grain or a grain (0·032 or 0·064 Gm.). It is not the active principle, and has no claim to the title, but contains more or less of the proper alkaloid.

CORYL is a mixture of methyl chloride and ethyl chloride. It has been used in dentistry and minor surgery as an anæsthetic.

CORYLUS ROSTRATA. Ait. *Beaked Hazel.* This is a small indigenous shrub of the nat. ord. Cupuliferæ, growing especially in mountainous districts. The nut is invested with a scaly involucre, projecting beyond it like a beak, and thickly covered with short spicula like those of *Mucuna pruriens*, D. C. (Nat. ord. Leguminosæ.) These spicula have been employed by Huebener as an anthelmintic. They operate in the same way as cowhage, and may be administered in the same manner and dose. (See *A. J. P.*, xiv. 280.)

COSAPRIN, $C_6H_4{<}^{SO_3Na\,(1)}_{NH—CO—CH_3\,(4)}$, is the acetyl derivative of sodium sulphanilate, and is obtained by the reaction of acetic anhydride upon the sodium salt of sulphanilic acid. Cosaprin forms a greenish-white finely crystalline tasteless powder, of a mild saline taste, freely soluble in water, difficultly soluble in alcohol, and almost insoluble in ether, forming a colorless solution with a weak acid reaction. It has been studied by V. Vámossy and Fenyvessy (*Therap. Monat.*, 1897), who find that it resembles phenacetin very closely in its action, but is characterized by the promptness and shortness of its influence.

COTARNINE HYDROCHLORATE. *Stypticin.* $C_{12}H_{15}NO_4.HCl$. This salt occurs in commerce in yellow crystals, readily soluble in water and alcohol. It is made by oxidizing narcotine, one of the opium alkaloids. The fact that the only chemical difference between hydrastinine and cotarnine is that in the latter OCH_3 is substituted for one atom of hydrogen led Dr. Freund to suggest the substitution of cotarnine in *dysmenorrhœa* and *menorrhagia* for hydrastinine; and on trial Gottschalk found that it was powerfully hæmostatic and also analgesic. The hæmostatic value of the drug has been confirmed by Gartig. (*Therap. Monat.*, 1896.) Falk (*Therap. Monat.*, vol. x., 1896) found that cotarnine produces in frogs paralysis by depression of the spinal cord, and in warm-blooded animals a slightly narcotic condition followed by paralysis, results of an influence respectively upon the cerebral cortex and the spinal cord. On the circulation it has no direct influence. On the respiratory centres it so acts as to produce a primary stimulation, soon followed after the large dose by lessened respiratory movements, and finally central asphyxia and death. If Falk be correct, that the drug has no primary influence upon the heart or blood-vessels, arrest by it of uterine hemorrhage must be due to an influence upon the uterus itself or its spinal centre.

In human medicine cotarnine has been given in doses of three-quarters of a grain (0·05 Gm.) from six to eight times a day, for a few days previous to and during the menstrual flow. It may be administered in capsules or dissolved in tincture of cinnamon. It has also been employed hypodermically, dissolved in distilled water.

COTO BARK. In the years 1873 and 1874 a bark bearing this name appeared in the London drug market, coming from Bolivia. Its botanical origin still remains unknown. Under the name of *coto-coto*, the bark of a rubiaceous plant (*Palicourea densiflora*) is employed in Brazil in *rheumatism*. Whether this be the Bolivian plant or not is uncertain. Beyond this point there has been much of surmise by writers, but no clear evidence.

Coto bark occurs in pieces a foot or more long, from three to four inches wide, and from one-half to three-quarters of an inch thick. The outer sur-

face is irregular, often looking as though it had been shaved or split off, and in other parts covered with a fine adherent epidermis free from lichens; the inner surface also is irregular, with numerous rather closely placed, longitudinal projecting bark bundles.

The general color approaches cinnamon-brown; upon fresh cross-section the bark is seen to be filled with yellowish spots, except in the outer portions. The odor is aromatic, and much more apparent if bruised; the taste hot, and somewhat aromatic; the powder is very pungent to the nostrils. The microscope shows the outer bark to be composed of thin-walled, colorless, parenchymatous cells, containing starch granules, with numerous yellowish sclerenchymatous cells joined into groups. The inner bark contains numerous yellow bark cells, mostly joined into bundles of from twenty to fifty. For microscopic structure, see *P. J. Tr.*, vi. 301, also *Pharm. Era*, May, 1888. The coto bark which we have seen in the American market conforms with the original description, but other barks are said to pass under the name. The most important of these is the so-called *Paracoto bark*, which is stated to differ from true coto bark chiefly in its having a less pungent odor and taste, and being marked with deep whitish furrows upon its surface. Wittstein found in coto bark a volatile alkaloid, a pungent aromatic volatile oil, yellowish-brown soft resin, brown hard resin, starch, gum, sugar, calcium oxalate, tannin, and formic, butyric, and acetic acids. (*Archiv d. Pharm.*, iii. 4, 219.) Jobst and Hesse have obtained a crystallizable body from coto bark (true), *Cotoin*, by making an ethereal extract from the powdered bark, treating this with warm benzin, and allowing the mixture to stand until clear. The clear liquid yields cotoin in crystals on spontaneous evaporation. The oily resinous residue contains considerable cotoin, which may be obtained by boiling with milk of lime and adding to the solution hydrochloric acid. After twenty-four hours the clear liquid will be found studded with large, glistening, laminated crystals of cotoin, of a pale yellow color. Cotoin, $C_{14}H_{12}O_4$, is sparingly soluble in cold water, more soluble in hot water, insoluble in benzin, very soluble in alcohol, chloroform, benzol, acetone, and carbon disulphide. Nitric acid becomes blood-red in contact with cotoin, sulphuric acid is colored brownish yellow, and ferric chloride blackens a dilute solution of cotoin.

Paracotoin, $C_{19}H_{12}O_6$, is extracted from paracoto bark, in which it exists associated with *oxyleucotin*, $C_{34}H_{32}O_{12}$, *leucotin*, $C_{34}H_{32}O_{10}$, *hydrocotin*, $C_{15}H_{14}O_4$, and *dibenzoylhydrocotin*, $C_{32}H_{32}O_8$. Paracotoin may be distinguished from cotoin by giving no reaction with ferric chloride. *Piperonylic* acid (*methyleneprotocatechuic* acid), $C_8H_6O_4$, is present in both barks. Coto bark is decidedly irritating; its powder, rubbed upon the skin, is said to produce heat and redness; and, according to Burkart, fifteen grains (0·971 Gm.) taken into the stomach produce persistent burning pain, followed by repeated vomiting. The remedy was first introduced as serviceable in *diarrhœa*, and seems to have established its reputation. Although observers are not explicit upon this point, it is evident that when there is a tendency to acute inflammation it must be used with great caution. The *paracoto* bark is said to resemble it in its action, but to be much less powerful. The fluid extract and tincture are very eligible preparations, the former made with alcohol in the usual way, and the tincture 1 part in 10 of alcohol, which may be given in from five- to fifteen-minim (0·31–0·92 C.c.) doses every two or three hours. The alkaloid cotoin is given by Dr. Burkart in doses of three-quarters of a grain (0·048 Gm.) every two or three hours. He states that he could detect it in the urine from four to six hours after the ingestion of the dose. Prof. Balz (Tokio, Japan) is said to have treated *cholera* successfully by hypodermic injections of three grains (0·194 Gm.) of paracotoin. Oxyleucotin, leucotin, and hydrocotin are very feeble. The value of cotoin in the treatment of *diarrhœa* has been confirmed by various clinicians. It has been used in catarrhal diarrhœas and the *diarrhœas* of *tubercular ulceration*, of *typhoid fever*, and of other conditions. (See *Bull. de Thérap.*, vol. xi. 167.) It does appear to have some especial effect upon the alimentary canal, as, according to Pribram (*Prager Med. Wochens.*, 1880) and Albertoni (*Arch. f. Exper. Path. u. Pharm.*, xvii. 293), it markedly lessens the excretion of indican. Albertoni also believes that it actively dilates the abdominal vessels and thereby hastens absorption; and Bibrana, that it is an antiseptic. It is not probable that cotoin has any general action upon the system, and Jobst found that even fifteen grains (0·971 Gm.) injected hypodermically into the rabbit produced no other than local symptoms. Dose of cotoin, from one to three grains (0·064–0·194 Gm.); of fluid extract, from five to twenty minims (0·3–1·3 C.c.), four to six times a day.

COTULA. *U. S.* 1870. *Mayweed.* (*Camomille puante*, *Maroute*, Fr.; *Hunds-Kamille*, *Stinkende-Kamille*, G.; *Camomilla fetida*, *Cotula*, It.; *Manzanilla loca*, Sp.) *Anthemis Cotula.* L. *Maruta Cotula.* De Cand. *Herba Chamomillæ Fœtidæ. Wild Chamomile. Dog Chamomile. Herbe de Camomille Puante*, *Herbe de Maroute*, Fr. *Hunds-Kamillenkraut*, G. The mayweed is an annual composite plant, with a fibrous root, and an erect, striated stem, very much branched even to the bottom, from one to two feet in height, and supporting alternate, sessile, flat, doubly pinnated, somewhat hairy leaves, with pointed linear leaflets. The flowers stand singly upon the summits of the branches, and consist of a central, convex, golden-yellow disk, with white ray florets, which spread horizontally during the day, but are reflexed, or bent towards the stem, at night. The calyx, which is common to all the florets, is hemispherical, and composed of imbricated hairy scales. The receptacle is conical or nearly cylindrical, and surmounted by rigid, bristle-shaped paleæ, shorter than the florets. The achenes are naked. This plant grows abundantly both in the United States and in Europe. In this country it is found in the vicinity of inhabited places, growing among rubbish, along the sides of roads, and in waste grounds. It flowers from the middle of summer till late in autumn. Mr. W. H. Warner found in the flowers volatile oil, oxalic, valerianic, and tannic acids, coloring matter, acrid fatty matter, bitter extractive, and salts of potassa, lime, magnesia, and iron. (*A. J. P.*, 1858, 390.) Pattone (1859) claimed to have found an alkaloid, *anthemidine*, and a crystallizable bitter acid, *anthemidic acid*, but his results have not been confirmed. The whole plant has a strong, disagreeable smell, and

a warm, bitter taste, and imparts these properties to water.

The medical properties of this species of Anthemis are essentially the same as those of chamomile, for which it may be substituted; but its disagreeable odor is an obstacle to its general use. On the continent of Europe it has been given in *hysteria* as an antispasmodic. It has also been thought to be emmenagogue. It is said to have the property of vesicating, if applied to the surface fresh and bruised. The whole plant is active; but the flowers, being less disagreeable than the leaves, are preferred for internal use. The remedy is best administered in the state of infusion.

COTYLEDON UMBILICUS. L. *Navelwort. Penny-wort. Cotylet, Nombril de Vénus*, Fr. *Nabelkraut*, G. This is a perennial, herbaceous, succulent plant, of the nat. ord. Crassulaceæ. It is about six inches high, with fleshy, peltate, crenate leaves, and a flower-stem bearing, in the form of a spike, pale yellow, bell-shaped, pendulous flowers, which appear in June and July. The plant is a native of England, where it grows upon old walls and rocks, and dry sandy banks.

According to M. Flétet, it contains *trimethylamine*, combined with an unknown acid. When the powder of the plant is exposed to the air, it attracts moisture, and exhales a disagreeable smell strikingly analogous to that of fish; and an extract treated with a fixed alkali disengages, even in the cold, an odor which, at first ammoniacal, soon acquires the fishy character referred to. The plant contains cellulose, starch, glucose, mucilage, chlorophyll, yellow coloring matter, a volatile oil smelling like sandarac, tannin, iron, and salts of potassa, soda, lime, and oxide of iron, with 0·9 per cent. of nitre, and 95 of water. (*Ann. de Thérap.*, 1865, 125.) It has been highly lauded in *epilepsy* (for references, see 16th ed. *U. S. D.*), but it has very feeble and uncertain therapeutic properties. Dose, of fresh juice, from one-half to one fluidounce, twice or three times a day; of fluid extract, one fluidrachm; of dry extract, five grains; to be increased and given steadily for months.

COW TREE. *Palo de Vaca. Palo de Leche.* The milky juice of the *Brosimum galactodendron*, D. Don (nat. ord. Urticaceæ), is much used in South America instead of cream in tea and coffee, etc. It is obtained by making incisions in the tree, is white and viscous, turns sour on exposure to the air, and deposits a caseous substance. According to the analysis of M. Boussingault, its composition varies very much, but it always contains a large percentage of fatty matters (32·2 per cent.), and much less casein, albumen, sugar, and phosphates. (*P. J. Tr.*, ix. 679.)

CRAB ORCHARD SALT. A mild, saline purgative, obtained by evaporating the waters of springs at Crab Orchard, Lincoln County, Kentucky. Its principal active ingredients are the magnesium, sodium, and potassium sulphates; it contains also a little iron and lithium. In its crude form it is not wholly soluble, and sometimes it is purified by dissolving and straining through flannel, and evaporating. As thus prepared, it is white, and as a purgative is about 20 per cent. stronger than the crude salt. It, however, lacks the tonic properties of the latter. According to Dr. R. Peter, the composition of the dry salt is: magnesium sulphate, 63·19 per cent.; sodium chloride, 4·77; sodium sulphate, 4·20; potassium sulphate, 1·80; calcium sulphate, 2·54; calcium, magnesium, and iron carbonates, and silica, 0·89; water of crystallization and loss, 22·61; total, 100·00. Dose from one to two teaspoonfuls. (See *A. J. P.*, 1874, 5.)

CRABS' CLAWS. *Chelæ Cancrorum.* These, finely powdered, were formerly official. In the 100 parts are 60 parts of calcium carbonate and 14 of calcium phosphate, with 26 of animal matter. They were formerly used as an absorbent and antacid.

CRABSTONES. *Lapilli Cancrorum. Crabs' Eyes. Oculi (Calculi) Cancrorum. Yeux (Pierres) d'Ecrevisses*, Fr. *Krebsaugen, Krebssteine*, G. Concretions found in the stomach, one on each side, of the European crawfish, at the time the animal is about to change its shell; chiefly procured in the province of Astrakhan, in European Russia. The crawfish are bruised with wooden mallets and laid up in heaps to putrefy. The animal remains are then washed away, and the stones picked out. They are inodorous, insipid bodies, somewhat hemispherical in shape, of a whitish or reddish color, hard and stony consistence, and laminated texture. They are very variable in size, weighing from one to twelve grains each. They effervesce with acids, and, without dissolving, become converted, owing to the animal matter which they contain, into a soft transparent mass, retaining the original shape of the stone. By this character they are distinguished from counterfeit stones, which are sometimes fabricated of chalk, mixed with mucilaginous substances. They consist of calcium carbonate and phosphate, cemented together by animal matter. Crabstones have been used as an absorbent and antacid, given in the same dose with prepared chalk.

CRANBERRIES. Fruit of *Vaccinium Macrocarpon*, Aiton. (Now *Oxycoccus macrocarpus*. Pers.) (Nat. ord. Vacciniaceæ.) These familiar berries, so well known as an article of diet, have come into notice as a source of citric acid. For method, see *Journ. de Pharm.*, 4e sér., xviii. 439. Mr. Edo Claassen announced in 1870 the existence of a bitter principle, *vacciniin*, in the *Vaccinium Vitis-idæa*, L., or *cowberry*. He subsequently (1885) proved its identity with *arbutin*. He failed to find arbutin in the cranberry, but states that the bitter principle here is uncrystallizable and a glucoside, and proposes the name *oxycoccin* for it. (*A. J. P.*, 1886.)

CREOSOTUM ALBUMINATUM. *Nutrin-creosote.* A yellow-gray powder, which is said to contain 40 per cent. of pure creosote and to be free from irritant action.

CREOSOTUM CARBONICUM. *Creosote Carbonate. Creosotal.* This is a mixture of the phenol-carbonates of the several constituents of creosote, and is obtained by the action of carbon oxychloride upon the phenol-sodium compounds of creosote. It is a thick, oleaginous, pale yellow, almost tasteless liquid, soluble in ethylic and methylic chloroform, in benzol, and in fatty oils; insoluble in water; having an oleaginous taste, which after a time suggests that of creosote. Its specific gravity is from 1·165 to 1·168. It contains 90 per cent. of pure creosote and is analogous to guaiacol carbonate.

It is stated that this substance is free from the poisonous activity of creosote and is well tolerated by the digestive apparatus, and that it has the activity of creosote in *phthisis* and other forms of *tuberculosis*, in chronic *bronchitis* and *enteritis*,

ulcerations, *intestinal indigestion*, and in various other derangements of the alimentary canal. It is decomposed in the system, as the odor of creosote is imparted to the breath and the urine becomes blackish from the appearance in it of the educts from creosote. There is much clinical testimony as to the value of the remedy, which seems to be growing in professional favor. In Leyden's clinic, in Berlin, it has been found greatly to lessen the fever and the night-sweats of *phthisis*. Four drachms a day, and even larger amounts of it, may be given to the adult without producing disagreeable symptoms. It may be administered in capsules, in emulsion dissolved in wine, or added to cod-liver oil. Fifteen drachms a day are asserted to have been given without any unpleasant symptoms. An emulsion in milk affords the best method of administering large doses. It has been used to a considerable extent hypodermically. Before the administration it should be warmed, so as to obtain complete fluidity.

CREOSOTUM TANNICUM. *Creosal. Tannosal.* The tannic acid ester of creosote. Creosal is a compound of creosote and tannin. It is obtained by heating equal quantities of beechwood creosote and pure tannin to 80° C. and adding gradually phosphorus oxychloride and purifying the product. It is soluble in water, alcohol, glycerin, and acetone, and occurs as a dark brown, hygroscopic powder. It is astringent and antiseptic, and may be given in daily doses of forty-six grains (3 Gm.), representing 1·8 Gm. of creosote.

CREOSOTUM VALERIANICUM. (*Eosote.*) A mixture of the valerianic esters of the phenols contained in creosote. It forms a rather mobile oily liquid, boiling at about 240° C., and soluble in alcohol and ether. This substance as an internal medicine is practically identical with the creosote carbonate.

CRESCENTIA CUJETE. The fruit of this South American plant has been found by Mr. Gustav Peckolt to contain *crescentinic acid* and a blue coloring matter allied to indigo. (*Pharm. Rundschau*, Aug. 1884.)

CRESOLS. *Cresylic Acid.* $C_6H_4(CH_3)OH$. These compounds are the first homologues of phenol or carbolic acid. (See *Acidum Carbolicum.*) There are three isomeric cresols: *orthocresol*, melting at 31° C. and boiling at 188° C.; *metacresol*, a liquid boiling at 201° C., but not solidifying even at —80° C.; and *paracresol*, forming colorless prisms, melting at 36° C. and boiling at 198° C. These cresols are all obtainable by fractional distillation from that portion of coal-tar boiling between 200° and 210° C. Although Fraenkel long since established the germicidal activity of the cresols, their insolubility prevented their practical use. Recently, however, attempts have been made to overcome this difficulty, and various preparations have been brought forward. The most important of these are Creolin and Lysol, Solveol, Solutol, Paracresol, and Cresolsalicylates.

Creolin is said to be an emulsion of cresol, obtained by means of resin soap. There are in the market at least two sets of preparations, the one of German the other of English origin. An analysis of Creolin-Pearson, published by Pfrenger (*Archiv der Pharm.*, 1890, 701), gives: phenols, 2·67; hydrocarbons, 44·94; organic bases, 2·76; sodium, 1·45; resin, 32·45; sulphur, 0·248; chlorine, 0·14; water (by difference), 5·34. The phenols consisted of ortho- and meta-cresol, with traces of carbolic acid and the oxyleucols; the hydrocarbons, of the higher homologues of benzene, with naphthalene and anthracene; the bases belonged to the quinoline group. Creolin forms a milky emulsion or mixture with water; with chloroform, ether, and absolute alcohol it mixes in all proportions. It is sometimes called *cresoline* or *sanatol*.

Medical Properties. According to Dr. Jessner, the first report upon creolin was that of Dr. F. von Esmarch (*Centralb. für Bacteriologie*, Bd. ii., Nos. 10 and 11), who stated, as the result of experiments made with creolin and carbolic acid upon putrefactive bacteria and upon the bacteria of *cholera*, *typhoid fever*, and *anthrax*, that it was much more powerful than carbolic acid as a germicide, except in the case of the anthrax bacillus. It is claimed for creolin that it is not poisonous. Dr. Jessner (*Lond. Med. Rec.*, Aug. 1889) gave eight ounces (250 Gm.) to a cow without any effect; and daily doses of one hundred and twenty grains (7·77 Gm.) were given to a man without any bad general symptoms, or any noticeable effect except decrease of intestinal gases and limitation of the putrefactive processes in the intestine. The urine also required longer than usual for ammoniacal fermentation. In a case reported by Dr. Kortüm, nine hundred grains (60 Gm.) are said to have been taken without bad effects, whilst in a case reported by S. Korach (*Deutsch. Med. Wochen.*, xxi. 1895), seventy-five grammes of creolin were taken for suicidal purposes. Although both coma and collapse, with complete loss of corneal reflexes, and tracheal râles, also vomiting and diarrhœa, occurred, the patient finally recovered without permanent injury. It is true that Neudörfer (*Internat. Klinisch. Rundsch.*, April, 1888) has shown that injection of creolin into the venous circulation of dogs produces a marked effect, but this may be mechanical, connected with the insolubility of the remedy. Fatal human poisoning by creolin has, however, occurred. Dr. Bitter (*Brit. Med. Journ.*, 1890) has seen restlessness, anxiety, nausea, amblyopia, and a tendency to syncope, with a peculiar strong taste of tea or smoke, produced by the drug. The urine in some of these cases was dark and strongly albuminous, evidently acute nephritis having set in. Dr. Fliesburg (*Northwestern Lancet*, Dec. 1891) details a case of a three-weeks-old babe who was killed by thirty drops of undiluted creolin, the chief symptoms being those of violent irritation of the mouth and upper respiratory and digestive tracts. Death occurred chiefly through inflammation of the glottis.

Compared with other antiseptics, creolin seems to be innocuous. Externally, according to Neudörfer, the solution of 1 to 5 per 1000 is non-poisonous and very antiseptic. He claims that it does not affect the hands or instruments of the surgeon, and is the best of the antiseptics for practical purposes. *Creolin gauze*, as usually sold, contains from 5 to 10 per cent. of the creolin; Neudörfer believes that the 1 per cent. is sufficiently strong. He recommends, especially for local use, the creolin in a powder combined with asbestos, in the proportion of 5 to 100; and for the disinfection of catheters and other instruments, a 33 per cent. solution with olive oil.

Internally, creolin is probably a very important remedy when it is desired to check fermentation in

the alimentary canal. Locally applied, it has been largely used with great success in the treatment of *scabies*, in the form of a 5 per cent. ointment with vaseline. In *ammoniacal cystitis*, washing out the bladder with a half per cent. solution of creolin has yielded excellent results. It also seems to be a very effective local application in the treatment of *acute* and *chronic dysentery*, and also in the *cholera morbus of children*. In the case of adults, large enemas of a one-half of one per cent. solution may be used; in the case of infants the strength should be about one-half of this. As a local application in *gonorrhœa*, creolin has been used with alleged most excellent results, both in the form of bougies containing half a grain of creolin and the injection of creolin dissolved in olive oil (1 in 3). For washing out the uterus after *labor*, the strength of the creolin solution should be 1 per cent.

Creolin is recommended by Jaksch as a deodorant to iodoform; a mixture of from 1 to 2 per cent. of creolin with iodoform produces a compound *creolin-iodoform* of a faint aromatic odor, soluble in alcohol and ether, and believed to possess the therapeutic properties of iodoform. Water removes from it the creolin and leaves the iodoform.

Lysol is made by dissolving the fraction of tar oil which boils between 190° and 200° C. in fat, and subsequently saponifying with the addition of alcohol; it is a brown, oily looking, clear liquid, with a feebly aromatic, creosote-like odor. It is described as containing 50 per cent. of cresols, miscible with water (forming a clear, saponaceous, frothing liquid), also with alcohol, petroleum spirit or benzin, chloroform, carbon disulphide, and glycerin. To the aqueous solution of the saponified cresols and fat may be added any desired quantity of the higher phenols.

Lysol was introduced as a disinfectant by Dr. V. Gerlach (*Zeit. für Hygiene*, June, 1891), who, as the result of an elaborate research, found that both in pure cultures and in mixed masses of pathogenetic bacteria it is more powerful as a germicide than is carbolic acid or creolin; that its 1 per cent. solution has a soapy feeling, and can be used for the purpose of disinfecting the hands without the use of soap; that for the purposes of disinfecting sputa and stools it is by far the most powerful of the germicides; that it is free from irritating properties, unless in strong solution, so that wounds may be sprayed with a 3 per cent. solution and absolutely disinfected; and that comparatively it is much less poisonous than carbolic acid, corrosive sublimate, or even creolin. 1 or 2 per cent. solutions were said to produce some slight transient burning when brought in contact with the mucous membranes. According to Lemke and Straube, a 0·3 per cent. solution will, in fifteen minutes, completely arrest the development of pus organisms, and a 0·5 per cent. solution even remove the odor of putrefying flesh. The value of lysol as an antiseptic has been confirmed by Vulpius, by Michelsen, and other surgeons, and there can be little doubt as to its applicability to the needs of antisepsis, although various surgeons seem to find it a little more irritating than at first stated, and some condemn it as not superior to the older antiseptics. Szuman (*Nowiny Lekarskie*, June, 1891) affirms that a stronger than 1 per cent. solution produces irritation, and that even two parts to a thousand are irritating to the bladder. It does not injure the surgeon's hands or his metallic or rubber instruments; but celluloid articles are said to become friable and useless under its action. It is not free from poisonous properties, and may produce fall of temperature, and depression with nephritis.

Solveol and *Solutol* are said to be respectively solutions of sodium cresotate in excess of cresol, and of cresol in excess of sodium cresotate. They are affirmed to be about as poisonous as carbolic acid. Solveol has been especially praised, it being affirmed to be distinctly more powerful than carbolic acid as a germicide, and in a one-half to five per cent. solution a very valuable antiseptic, especially in major gynæcological operations. (See *Deutsch. Med. Wochen.*, Sept. 1892; *Journ. Méd. de Paris*, 1892.)

Paracresol is a patented disinfectant, to which the formula $C_6H_4 \begin{cases} CH_3\ (1) \\ OH\ (4) \end{cases}$ is ascribed. It is said to give with water in every proportion a pure, neutral, non-caustic, almost odorless solution, similar to that of carbolic acid, but more active and safer. It is evidently not paracresol, before described, as that has odor and is difficultly soluble in water.

Tricresol is a clear, colorless liquid, of a creosote-like odor, a specific gravity of from 1·042 to 1·049, and boiling between 185° and 205° C. It is soluble in cold water to the extent of from 2·2 to 2·5 per cent., and forms a clear solution; thus showing it to be free from neutral-oil, naphthalene, etc. It is said to be composed of orthocresol, 35 per cent.; metacresol, 40 per cent.; paracresol, 25 per cent.

The concurrent testimony of Grüber (*Archiv für Hygiene*, 1893), of Walter Reed, U.S.A. (*St. Louis Med. and Surg. Journ.*, 1894), of Charteris (*Lancet*, 1894), and other investigators and surgeons, show that tricresol is a very active germicide, which is probably three times as powerful as pure phenol. Its 1 per cent. solution even in the presence of albuminous fluids readily destroys pathogenetic bacteria. It may be used for all the purposes for which carbolic acid is employed. It is said to affect the skin of the operator much less than does carbolic acid, and to be much less irritating to wounds than either carbolic acid or bichloride solutions. It does not act on surgical instruments. For the ordinary purposes of surgery the 1 per cent. solution may be employed. It is probably less toxic than carbolic acid. Charteris, indeed, claims that it is only one-third as active a poison as is phenol.

Ethylenediaminetricresol or *Kresamin* is a mixture of tricresol with ethylenediamine. It is a colorless aqueous liquid, having a carbolic-acid-like odor, and after standing in the air becomes of a light yellow color without losing disinfecting power. According to H. Eckstein, it is an exceedingly powerful antiseptic, especially adapted to the preserving of specimens for microscopic use. As a local application the same author has found it very valuable in those cases of *eczema* in which there was a pronounced secondary infection of the skin, and also in *sycosis* and similar parasitic diseases. Bandages of it wet with a solution of from 1 to 4000 to 1 to 400 were kept applied to the part. In *lupus* and some similar conditions local protracted baths of from three to twelve hours' duration, with a concentration of 1 to 4000, were found efficacious. From 10 to 15 per cent. salves of it were also employed.

CRESOL IODIDE. *Iodocresol. Traumatol.* $C_6H_3.I.(CH_3)OH$. This is formed by the action of potassium iodide solution upon an emulsion of cresol and water. It contains but one atom of iodine, while losophan or cresol triiodide contains three atoms, and, consequently, a higher percentage of iodine. This is a violet-red, odorless, amorphous powder; insoluble in water, acids, and alcohol; dissolving with difficulty in ether, readily in alkaline solutions, and freely in chloroform. It contains 55 per cent. of iodine, and has been commended as powerfully antiseptic, non-irritant, and having local anæsthetic properties. It is used locally in *syphilitic* and other *ulcers*, *eczema*, especially when attended with much discharge, *intertrigo*, and various other skin diseases. Also as a substitute for iodoform in surgery. In *herpes* a 10 per cent. traumatol collodium has been found very useful, and a 5 to 10 per cent. traumatol zinc ointment has been highly commended. Pure traumatol may also be used as a dusting powder.

CRESOL-NAPHTOL. A brown, viscous, tarlike liquid, insoluble in, but emulsifying with, water. Guinard states that it is a very active germicide, and that it is impossible to produce poisoning in the lower animals by giving by the mouth, largely on account of its inducing vomiting at once. Its aqueous solution, like that of other creolin products, has the disadvantage of depositing in wounds.

CRESOL SALICYLATES. *Cresalols. Cresol Salols.* $C_6H_4\begin{cases}OH\\COC_6H_4.CH_3\end{cases}$. Salicylates may be prepared from ortho-, meta-, or para-cresol by a process similar to that used in the making of salol. They are insoluble in water, slightly soluble in cold alcohol, and are easily crystallized. The *meta-cresol salicylate* is the cresalol generally referred to by that name. It fuses at 74° C., and is easily soluble in alcohol and ether. Mr. Nencki states that the cresalols decompose in the alimentary canal, and are efficient substitutes for salol, and less poisonous. (*Compt-Rend.*, Feb. 1889.)

CRESOL TRIIODIDE. *Meta-cresol Triiodide.* (*Losophan.*) $C_6HI_3(CH_3)OH$. A fine, yellowish powder, with a rather strong, not altogether disagreeable smell; insoluble in water, soluble in alcohol, ether, and chloroform, exceedingly so in oil. Merck (*Jahresbericht*, 1892, 77) describes it as obtained in colorless needles, fusing at 121·5° C. It contains 78·39 per cent. of iodine. A specimen prepared by Friedrich Baeyer & Co. was found by Petersen (*Münch. Med. Wochensch.*, July, 1891) to yield its iodine with difficulty, passing through the alimentary canal almost without absorption; applied to the mucous membrane of the nose in *acute inflammation*, it was found to act very well in checking secretion and lessening inflammatory action.

CRESOTINIC ACID, or *Cresotic Acid*, $C_6H_3\begin{cases}CH_3\\OH\\COOH\end{cases}$, may exist as ortho, meta, or para modification, and is the homologue of salicylic acid, bearing the same relation to cresol that salicylic acid does to phenol. The cresotic acids may be made artificially from the cresols by a reaction analogous to that used in making salicylic acid.

Only the para compound is used in medicine. It crystallizes in white needles, melting at 151° C. As long ago as 1876 *sodium cresotate* was proposed as an antipyretic, but the commercial drug furnished was proved to be a mixture of varying composition, and has been replaced by the pure sodium paracresotate, a white, finely crystallized powder, having a somewhat bitter taste, forming a permanent solution in twenty-four parts of hot water. It is made as stated by the Kolbe process of heating the sodium paracresol with carbon dioxide under pressure. M. Charteris (*Brit. Med. Journ.*, March, 1891) found that ortho- and para-cresotic acids act upon rabbits as poisons, the lethal dose being less than half a grain (0·032 Gm.) of the ortho, and one grain (0·064 Gm.) of the para, acid per pound. According to the experiments of Demme (*Wiener Med. Blätter*, Feb. 1870), sixty grains (3·88 Gm.) of the sodium paracresotate may be taken by man without producing very distinct symptoms, except an antipyretic action in cases of fever. The same authority used the drug with asserted good results in *acute articular rheumatism*. In some of the cases marked collapse occurred, in others erythematous eruption.

CROCUS OF ANTIMONY. *Saffron of Antimony.* This compound is formed during the deflagration of a mixture of equal weights of antimony tersulphide and potassium nitrate, to which one-twelfth of hydrochloric acid has been added. Fused crocus of antimony is in masses of a liver-brown color; the unfused is a saffron-brown insoluble powder, containing about four-fifths of teroxide, one-fifth of tersulphide. It was formerly used in making tartar emetic. (*Lond. Pharm.*, 1836.)

CRYPTOCARYA AUSTRALIS. Bentham. (Nat. ord. Laurineæ.) From the bark of this Queensland tree, Dr. T. L. Bancroft (*Austral. Journ. Pharm.*, March, 1887) has separated an alkaloid which is said to be a powerful respiratory poison.

CUCUMBER OINTMENT. An emollient ointment, prepared from the common cucumber (fruit of *Cucumis sativus*, L., nat. ord. Cucurbitaceæ), has been considerably employed in *irritated states of the skin*. The following is the mode of preparing it, recommended by Prof. Procter. Take of green cucumbers 7 pounds avoirdupois, pure lard 24 ounces, veal suet 15 ounces. Grate the washed cucumbers to a pulp, express, and strain the juice. Cut the suet into small pieces, heat it over a water-bath till the fat is melted out from the membrane; then add the lard, and, when melted, strain through muslin into an earthen vessel capable of holding a gallon, and stir until thickening commences, when one-third of the juice is to be added, and the whole beaten with a spatula till the odor has been almost wholly extracted. The portion which separates is to be decanted, and the remaining two-thirds of the juice are to be consecutively incorporated and decanted in the same manner. The jar is then closely covered and placed in a water-bath, until the fatty matter entirely separates from the juice. The green coagulum floating on the surface is now removed, and the jar put in a cool place that the ointment may solidify. The crude ointment is then separated from the watery liquid on which it floats, melted and strained, and placed in glass jars, which must be kept closely sealed. A layer of rose-water upon its surface will favor its preservation. A portion may be triturated with a little rose water until white and creamy, and put into a separate jar for present use. (*A. J. P.*, xxv. 409.)

M. Emile Mouchon prepares the ointment by obtaining the juice mixed with a little alcohol, and incorporating this with benzoinated lard and stearin. He directs 16 parts of the cucumber to be reduced to a pulp, 1 part of alcohol of 36° B. to be added, and the mixture to be placed on the diaphragm of a percolator. Twenty-four hours afterwards 10 parts of the liquid are obtained of 19° B. Of this liquid 6 parts are to be incorporated with 37·5 parts of benzoinated lard and 12·5 of stearin; the fatty matters having been previously melted together by means of a water-bath, and beaten vigorously on cooling. The liquid is to be added before the completion of the beating, which should then be continued until the whole becomes as light and white as possible. The benzoin and alcohol enable the ointment to keep a long time. (*Journ. de Pharm.*, Juillet, 1854, 41.) We prefer to make this ointment by incorporating one part of distilled *spirit of cucumbers* with seven parts of benzoinated ointment. The spirit is made by distilling a mixture of one part of grated cucumbers with three parts of diluted alcohol, retaining the first two parts or distillate which come over. This spirit is permanent, and ointment or cream made from it keeps well.

CUCURBITA CITRULLUS. L. (*Citrullus vulgaris*, Schrad; *Citrullus Citrullus* (L.), Karst.) *Watermelon.* The seeds of the watermelon are employed, to a considerable extent, as a domestic remedy in *strangury* and other affections of the urinary passages. They have similar properties with the seeds of the other Cucurbitaceæ, of which four different kinds were formerly official under the name of the *greater cold seeds*,—viz., those of the *Cucurbita pepo*, L., or pumpkin, the *Cucurbita Lagenaria* (now *Lagenaria vulgaris*, Ser.), or gourd, the *Cucumis melo*, L., or muskmelon, and the *Cucumis sativus*, or cucumber. These when bruised and rubbed up with water form an emulsion, which was formerly thought to possess considerable virtues, and was much used in *catarrhal affections*, *disorders of the bowels* and *urinary passages.* Watermelon-seeds are also esteemed by some as a diuretic. The infusion of two ounces of the bruised seeds to a pint may be taken *ad libitum.* In the form of *Arbooznyi miod*, or *watermelon honey*, or as a freshly expressed juice, the Russian peasants are said to employ watermelon in the treatment of *dropsy*, *urino-genital affections*, *chronic hepatic congestion*, and *chronic intestinal catarrh.* Manassein (*Vrach*, Nov. 1881) found that the melon honey acts upon the lower animals as a very powerful diuretic, and causes when in sufficient dose fall of the arterial pressure, rapid pulse, and death from cardiac paralysis.

The pulp of the root of *Cucurbita Lagenaria*, or *gourd*, is said by Chapin to be a powerful and even drastic purgative, and to be used by the natives of the Sandwich Islands successfully in *dropsy.* (See *N. Y. Journ. of Med.*, 1855, 203.)

CULILAWAN. *Cortex Culilaban.* An aromatic bark, produced by *Cinnamomum Culilawan*, Blume (*Laurus Culilaban*, Linn.), a tree of considerable size, growing in the Molucca Islands, Cochin-China, and other parts of the East. It is usually in flat or slightly rolled pieces, several inches long, an inch or more in breadth, and one or two lines thick. Sometimes the bark is thinner and more quilled, bearing considerable resemblance to cinnamon. The epidermis is for the most part removed, but when present is of a light brownish-gray color, soft to the touch, and somewhat spongy. The color of the bark itself is a dull, dark, cinnamon-brown, the odor highly fragrant, the taste agreeably aromatic, and not unlike that of cloves. The active constituent is a volatile oil, smelling like a mixture of the oils of cajuput and cloves. Culilawan has the medical properties of the aromatics, but is scarcely used at present. (See *Cortex Caryophyllata.*)

CUMIN. Cyminum, *Lond.* Cuminum, *Ed.* *Cumin*, Fr. *Kreuzkümmel*, *Mutterkümmel*, *Römischer* (*langer*, *scharfer*) *Kümmel*, G. The so-called cumin seeds are the fruit of the *Cuminum Cyminum*, L., an annual umbelliferous plant, about six or eight inches high, having a round, slender, branching stem, with numerous narrow, linear, pointed, smooth, grass-like leaves, of a deep green color. The white or purple flowers are in numerous terminal umbels, which have very few rays, and are attended with general and partial involucres, consisting of three or four linear leaflets. The plant is a native of Egypt, but is cultivated for its fruit in Sicily, Malta, and other parts of Europe.

The cumin fruits (*seeds*) are elliptical, flat on one side, convex, furrowed, and rough on the other, about one-sixth of an inch in length, and of a light brown color. Each has seven longitudinal ridges. Two fruits are sometimes seen united together. Their odor is peculiar, strong, and heavy; their taste warm, bitterish, aromatic, and disagreeable. They contain much essential oil, which is lighter than water, yellowish, and has the sensible properties of the seeds. It consists of three distinct oils, one a hydrocarbon, *cymene*, $C_{10}H_{14}$, recognized now as *isopropyl-p-methyl-benzene*, another *cuminol*, $C_{10}H_{12}O$, which may be regarded as *cumin aldehyde*, $C_{10}H_{11}OH$, and the third a terpene, $C_{10}H_{16}$. Dumas, a long time since, obtained a cymene identical with that of oil of cumin seeds, by dehydrating camphor, and M. Paternó prepared it in a similar way from oil of turpentine. (*Journ. de Pharm.*, 4e sér., xx. 409.) In his discovery M. Paternó seems, however, to have been preceded by several chemists, Mr. C. R. A. Wright apparently having the priority. (*A. J. P.*, xlvi. 117; see especially *A. J. P.*, xliv. 452). Cumin aldehyde has also, together with cymene, been obtained from the seeds of *Cicuta virosa.* (Trapp, *Ann. Ch. Pharm.*, cviii. 386.) In medical properties cumin seeds resemble the other aromatic umbelliferous fruits. Dose, from fifteen grains to half a drachm (0·971–1·944 Gm.).

CUNILA MARIANA. L. (Now *C. origanoides.* (L.) Britt.) *American Dittany. Sweet Horsemint. Stone Mint.* A small indigenous perennial herb, growing on dry, shady hills, from New England to Georgia, and flowering in June and July. The whole herb has a warm pungent taste and a fragrant odor, dependent on an essential oil, which, according to Mr. Philip Milleman, of Chicago, is of reddish-amber color, becoming light yellow by exposure to light, of a delicate, fragrant odor, very similar to that of oil of monarda, of a warm, pungent taste, and of the sp. gr. 0·920. It is readily soluble in alcohol, ether, and chloroform. On spontaneous evaporation, it leaves a small crystalline residue. Iodine decomposes it, producing white vapors; by sulphuric acid it is reddened and decomposed, by nitric acid resinified, and by hydrochloric acid decolorized, though its color returns on exposure. It

is slightly rubefacient; in the dose of five or ten drops it is carminative, and of from fifteen to twenty drops diaphoretic. The same author found in the dried herb tannic acid, a trace of glucose, gum, bitter extractive, resin, and salts of potassa, lime, magnesia, and iron. (*A. J. P.*, Nov. 1866, 495.) American dittany is a gently stimulant aromatic, analogous to the mints.

CUPRI ACETAS. *U. S.* 1880. *Copper Acetate.* $Cu(C_2H_3O_2)_2\,H_2O$; 199·2. *Crystallized Verdigris. Crystals of Venus. Verdet, Cristaux de Vénus*, Fr. *Essigsaures Kupfer*, G. This salt may be prepared by dissolving verdigris in acetic acid, or by precipitating a concentrated solution of lead acetate with copper sulphate. It is the normal cupric acetate, as distinguished from the basic salts. "Deep-green, prismatic crystals, yielding a bright green powder, efflorescent on exposure to air, odorless, having a nauseating, metallic taste and an acid reaction. Soluble in 15 parts of water and in 135 parts of alcohol at 15° C. (59° F.), in 5 parts of boiling water and in 14 parts of boiling alcohol. When heated above 100° C. (212° F.), the salt loses its water of crystallization, and at a temperature above 200° C. (392° F.), it is gradually decomposed. The aqueous solution of the salt has a bluish-green color, which is rendered deep blue by an excess of ammonia. On heating the salt with sulphuric acid, acetous vapors are evolved. If the aqueous solution of the salt be treated with hydrosulphuric acid until all the copper is precipitated, the filtrate should leave no residue on evaporation (alkalies, alkaline earths, and iron). If the aqueous solution be heated to boiling with solution of soda in excess, it will yield a filtrate which should not be clouded by hydrosulphuric acid (abs. of lead, zinc)." *U. S.* 1880.

VERDIGRIS (*Impure Subacetate of Copper*, U. S. 1870; *Copper Subacetate; Aeruga*, P. G.; *Viride Æris, Ærugo*, Lat.; *Acétate de Cuivre brut, Vert-de-gris, Acétate basique de Cuivre, Verd-et-gris*, Fr.; *Grünspan, Spangrün, Basisches Essigsaures Kupfer* (*Kupferoxyd*), G.; *Verde Rame*, It.; *Cardenillo*, Sp.) is prepared in large quantities in the south of France, more particularly in the neighborhood of Montpellier. It is also manufactured in Great Britain and Sweden. In France the process is conducted in the following manner. Sheets of copper are stratified with the residue of the grape after the expression of the juice in making wine, and are allowed to remain in this state for a month or six weeks. At the end of this time the plates are found coated with a considerable quantity of verdigris. This is scraped off, and the plates are then replaced as at first, to be further acted on. The scrapings thus obtained form a paste, which is afterwards well beaten with wooden mallets, and packed in oblong leathern sacks, about ten inches in length by eight in breadth, in which it is dried in the sun, until the loaf of verdigris, as it is called, attains the proper degree of hardness. The rationale of the process is easily understood. The juice of the grape refuse undergoes the acetous fermentation, and the acetic acid attacking the copper forms the subacetate. In England a purer verdigris is prepared by alternating copper plates with pieces of woollen cloth steeped in pyroligneous acid. Verdigris comes to this country exclusively from France, being imported principally from Bordeaux and Marseilles. It occurs in masses of a pale green color, and composed of a multitude of minute silky crystals. Sometimes, however, it occurs of a bright blue color. Its taste is coppery. It is insoluble in alcohol, and, by the action of water, a portion of it is resolved into the neutral acetate which dissolves, and the tri-acetate which remains behind in the form of a dark green powder, gradually becoming black. It is hence evident that, when verdigris is prepared by levigation with water, it is altered in its nature. When verdigris is acted on by sulphuric acid, it is decomposed, vapors of acetic acid being evolved, easily recognized by their vinegar odor. It is soluble almost entirely in ammonia, and dissolves in hydrochloric and dilute sulphuric acids, with the exception of impurities, which should not exceed 5 per cent. When of good quality, it has a lively green color, is free from black or white spots, and is dry and difficult to break. The green rust, called in popular language verdigris, which copper vessels are apt to be coated with when not kept clean, is a copper carbonate, and should not be confounded with true verdigris. Verdigris, apart from its impurities, is a variable mixture of the basic copper acetates.

The *blue* variety has approximately the composition $(C_2H_3O_2)_2Cu,Cu(OH)_2 + 5H_2O$. When treated with water it is gradually decomposed into two parts, according to the reaction: $3(Cu(C_2H_3O_2)_2,Cu(OH)_2) = Cu(C_2H_3O_2)_2 + 2Cu(OH)_2$ and $2Cu(C_2H_3O_2)_2 + Cu(OH)_2$. The latter of these products constitutes the *green* variety of verdigris. (Flückiger, *Pharm. Chem.*, 758) The local and general action of verdigris upon the animal economy and the treatment of its poisoning are the same as those of copper sulphate. It is never used internally.*

CUPRI ARSENITUM. *Copper Arsenite. Scheele's Green.* This salt was brought forward for the purpose of treating *diarrhœa* on the homœopathic principle, in the *Symptomen Codex* of Jahn, in 1865, and has been greatly lauded by John Aulde and other regular practitioners in the treatment of *diarrhœa, entero-colitis, cholera morbus*, and *dysentery*. It is to be given in doses of from one-three-thousandth to one-two-thousandth of a grain (0·00013–0·00020 Gm.), at intervals of from ten to twenty minutes, until some effect is produced. It does not seem to be sustaining its first reputation.

CUPRI NITRAS. *Br.* 1885. *Nitrate of Copper. Cupric Nitrate.* $Cu(NO_3)_2,3H_2O$. "May

* *Linimentum Æruginis, Mel Ægyptiacum, Unguentum Ægyptiacum.* This is an old preparation, formerly official in Great Britain. The following is the process for it given in the old *London* Pharmacopœia. "Take of Verdigris (Subacetate of Copper), in powder, *an ounce;* Vinegar *seven fluidounces;* Honey *fourteen ounces.* Dissolve the Verdigris in the Vinegar, and strain through linen; then gradually add the Honey, and boil down to a proper consistence." The ounces used here are troyounces. It sometimes happens, during the boiling of the acetic solution of the verdigris, that a red deposit rapidly forms, consisting of the red or suboxide of copper (cuprous oxide); and that at the end of the process little or none of the metallic salt remains in the preparation. This happens especially when graular honey is employed. (Harley, *P. J. Tr.*, xi. 357.) The change is owing to the decomposition of the cupric oxide by the grape sugar of the honey, converting it into cuprous oxide. The inference is that, in making the preparation, so as to fulfil the objects of the original prescription, simple syrup should be used. It was formerly employed, either undiluted or mixed with some mild ointment, to destroy *fungous granulations* or to repress their growth. In the latter state it acts as a stimulant to *flabby, indolent*, and *ill-conditioned ulcers;* and, largely diluted with water, it has been used as a gargle in *venereal ulcerations* of the mouth and throat. It is sometimes also applied undiluted, by means of a camel's-hair brush.

be obtained by dissolving copper in diluted nitric acid and evaporating the solution until crystallization takes place on cooling to a temperature not lower than 70° F. (21·1° C.)." *Br.* 1885. This salt was introduced in the 1885 revision of the British Pharmacopœia, to be dropped in 1898. As obtained by the above process, the crystals are prismatic and of a deep blue color, and very deliquescent and corrosive. At a temperature below 70° F. (21·1° C.), with one-third of its weight of water it forms tabular crystals which have the composition $Cu(NO_3)_2,6H_2O$. The addition of a very little more water causes the crystals to form a styptic and caustic fluid. The diluted aqueous solution should show only a faintly acid reaction to litmus-paper. This salt has the physiological and medical properties of copper sulphate, and may be used in the same dose.

CUPRUM AMMONIATUM. *Ammoniated Copper. Cuprum Sulfuricum Ammoniatum*, P.G. *Ammonio-sulphate of Copper*, E. *Sulfate de Cuivre ammoniacal, Cuivre ammoniacal*, Fr. *Schwefelsaures Kupferoxyd-Ammoniak* (*Kupfer-Ammonium, Cuprammonium*), G. "Take of Copper Sulphate *half a troyounce;* Ammonium Carbonate *three hundred and sixty grains.* Rub them together in a glass mortar until effervescence ceases. Then wrap the Ammoniated Copper in bibulous paper, dry it with a gentle heat, and keep it in a well-stopped glass bottle." *U. S.* 1870.

When the two salts above mentioned are rubbed together, a reaction takes place between them, attended with the elimination of the water of crystallization of the copper sulphate, which renders the mass moist, and with the simultaneous escape of carbonic acid gas from the ammonium carbonate (sesquicarbonate), which occasions an effervescence. The color is at the same time altered, passing from the light blue of the powdered copper sulphate to a beautiful deep azure. The nature of the chemical changes which take place in the formation of what is commonly called "ammoniated copper" depends somewhat upon the conditions of action. When anhydrous cupric sulphate is exposed to the action of dry ammonia gas, the mass becomes heated, and a deep blue powder, $CuSO_4 + 5NH_3$, results, which on exposure to the air is capable of exchanging the 5 mols. of ammonia for a corresponding amount of water. If, on the other hand, one part of powdered cupric sulphate be added to three parts of ammonia solution (sp. gr. 0·960), and after the subsidence of any ferric hydrate present as impurity, six parts of alcohol be added to the clear liquid, crystals will be formed of the composition $CuSO_4 + H_2O + 4NH_3$. If this preparation be allowed to remain exposed to the air, it will lose ammonia and water, and be changed into a mixture of basic sulphates. Ammoniated copper sulphate loses one molecule of NH_3 at 200° C. (392° F.), and at 260° C. (500° F.), only anhydrous sulphate remains, which frequently, however, contains cuprous oxide.

This salt has a beautiful deep azure-blue color, a strong ammoniacal odor, and a styptic, metallic taste. It is soluble in water, and the solution has an alkaline reaction on vegetable colors; but, unless there is excess of ammonium sesquicarbonate, the solution deposits copper subsulphate if much diluted. When exposed to the air it parts with ammonia, and is said to be ultimately converted into ammonium sulphate and copper carbonate. This change is apt to occur, to a greater or less extent, while it is drying. It should not, therefore, be prepared in large quantities at a time, and should be kept in well-closed bottles. By heat the whole of it is dissipated, except the copper oxide. Arsenous acid precipitates a green copper arsenite from its solution. Potassa, soda, lime water, and the acids are incompatible with it. Ammoniated copper was formerly much employed in *epilepsy*, *chorea*, *hysteria*, etc. It is at present very seldom exhibited. In overdoses it produces vomiting, and the poisonous effects which result from the other preparations of copper. Dose, in pill or solution, a quarter or half a grain (0·016 or 0·03 Gm.), twice a day, and gradually increased to four or five grains (0·26 or 0·33 Gm.).

CURCUMA. *U. S.* 1870. *Turmeric. Curcuma Longa.* L. (Nat. ord. Scitamineæ.) The root of this plant is perennial, tuberous, palmate, and internally of a deep yellow or orange color. The leaves are radical, large, obliquely nerved, sheathing at their base, and closely embrace each other. The scape or flower-stem, which rises from the midst of the leaves, is short, thick, smooth, and constitutes a spike of numerous imbricated bracteal scales, between which the flowers successively make their appearance. The plant is a native of the East Indies and Cochin-China, and is cultivated in various parts of Southern Asia, particularly in China, Bengal, and Java, whence the root is exported. The best is said to come from China.

The dried root (*Safran des Indes, Souchet des Indes*, Fr.; *Kurkuma, Gelbwurz*, G.; *Curcuma*, It., Sp.; *Zirsood*, Arab.; *Huldie*, Hindoo) is in cylindrical or oblong pieces (*Curcuma longa*), about as thick but not as long as the finger, tuberculated, somewhat contorted, externally yellowish brown or greenish yellow, internally deep orange-yellow, hard, compact, breaking with a fracture like that of wax, and yielding a yellow or orange-yellow powder. Another variety (*Curcuma rotunda*), comparatively rare, is round or oval, about the size of a pigeon's egg, and marked externally with numerous annular wrinkles. Sometimes it comes cut into two transverse segments. The two varieties have a close resemblance in sensible properties, and are thought to be derived from the same plant, though formerly ascribed to different species. The odor of turmeric is peculiar; the taste warm, bitterish, and feebly aromatic. It tinges the saliva yellow. Analyzed by Pelletier and Vogel, it was found to contain lignin, starch, a peculiar yellow coloring matter called *curcumin*, a brown coloring matter, gum, an odorous and very acrid volatile oil, and a small quantity of calcium chloride. Curcumin was obtained, mixed with a little volatile oil (about 1 per cent.), by digesting the alcoholic extract of turmeric in ether, and evaporating the ethereal tincture. It has been obtained, by F. A. Daube, in deep yellow crystals, of a diamond lustre, by a process which may be found in the *A. J. P.* (1871, 308). C. L. Jackson and Menke have submitted turmeric root to a thorough examination, and give the following results. The turmeric oil is first removed from the ground root by treatment with ligroine, then the curcumin mixed with a large quantity of resin is extracted with ether, and finally purified by crystallization from alcohol. The oil extracted by ligroine was dark yellow, and amounted to 11 per cent. of the root. The purified curcumin amounted

to 0·3 per cent., and melted at 178° C. (352·4° F.). Analyses of the pure curcumin, of several of its salts, and of derivatives, show its formula to be $C_{14}H_{14}O_4$. (*Am. Chem. Journ.*, iv. 77.) It is brown in mass, but yellow in the state of powder, without odor or taste, insoluble in benzin, scarcely soluble in water, but very soluble in alcohol, ether, and the oils. It is a diatomic monobasic acid. When treated with weak oxidizing agents it yields vanillin. The alkalies rapidly change its color to a reddish brown; and paper tinged with tincture of turmeric is employed as a test of their presence. When treated with a mixture of sulphuric and boric acids it yields a product called *rosocyanin*, because it dissolves in alcohol with a fine red color, and is turned blue by alkalies. Its alcoholic solution produces colored precipitates with lead acetate, silver nitrate, and other salts. Turmeric is used for dyeing yellow; but the color is not permanent. Mr. James Cook has found in turmeric an alkaloid, which forms crystallizable salts with sulphuric and nitric acids, and, separated from these acids by ammonia, yields a semi-crystalline precipitate. He observed also indications of a second base. (*P. J. Tr.*, Nov. 1870.) Ivanow Gajewsky also states that there is an alkaloid in the root. (*Pharmacographia*, 641.)

This root is a stimulant aromatic, bearing some resemblance to ginger in its operation, and is much used in India as a condiment. It is a constant ingredient in the curries so generally employed in the East. In former times it had some reputation in Europe as a remedy in *jaundice*; but at present it is employed only to impart color to ointments and other pharmaceutic preparations.

Turmeric paper, used as a test, is prepared by tingeing white unsized paper with a tincture or decoction of turmeric. The tincture may be made with one part of turmeric to six parts of proof spirit; the decoction, with one part of the root to ten or twelve of water. The access of acid or alkaline vapors should be carefully avoided.

AFRICAN TURMERIC. Dr. Wm. F. Daniell has brought into notice a product, much used by the native Africans of Sierra Leone in dyeing, consisting of rhizomes, closely resembling the East Indian turmeric, having a similar odor and taste, and in like manner tingeing the saliva yellow, and imparting their coloring matter readily to alcohol and water. He found it to be derived from a Canna, supposed to be the *C. speciosa* of Roscoe (now *C. indica*, L.). (*P. J. Tr.*, 1859.)

CURRY LEAVES. *Currie.* The leaves of the *Murraya Koenigii*, Spreng. (nat. ord. Rutaceæ), a tree of India, are very largely used in that country as an aromatic, stomachic stimulant; when powdered and mixed with spices and other substances it forms *curry powder*, which is much used for seasoning food, rice, cooked dishes, etc.; it is also employed in *dyspepsia*, *diarrhœa*, and even *dysentery*. According to Mr. J. G. Prebble (*Pharmacographia Indica*, vol. i.), curry leaves yield to distillation a small quantity of volatile oil, and also contain a greenish-black resin, and a glucoside, *Koenigin*. The clear oil extracted from the seeds is known as *Simabolee oil*.

CUTTLE-FISH BONE. *Os Sepiæ*, *Os de Sèche*, Fr. *Sepie*, *Weisses Fischbein*, G. This is a calcareous body, situated underneath the skin, in the back of the *Sepia officinalis*, or *cuttle-fish*, of European seas. It is oblong-oval, from five to ten inches long, and from one and a half to three inches broad, somewhat convex on both sides, with thin edges, of a rather firm consistence upon the upper surface, very friable beneath, and composed of numerous layers, loosely connected, so as to give to the mass a porous consistence. It is lighter than water, of a white color, a feeble sea odor, and a saline taste. It contains, according to John, from 80 to 85 per cent. of calcium carbonate, besides animal matter, a little common salt, and traces of magnesia. Its fine powder may be given as an antacid, and it is sometimes used as an ingredient of tooth-powders. Small pieces of it are often put into bird-cages that the birds may rub their bills against them; and the powder is employed for polishing. Another product of the cuttle-fish is a blackish-brown liquor, secreted by a small gland into an oval pouch, communicating externally near the rectum by a long excretory duct, through which the animal is said to have the power of ejecting it at will. This, when taken from the fish, is dried, and used in making the water-colors *sepia* and *India ink*.

CYCLAMEN EUROPÆUM. L. *Pain de Pourceau*, *Arthanite*, Fr. *Erdscheibe*, *Erdbrot*, *Schweinebrot*, G. *Sow-bread.* This is an herbaceous, perennial, stemless plant, belonging to the natural order Primulaceæ, which is indigenous in the south of Europe, and cultivated in gardens for the beauty of its purple flowers with reflected petals. The root is globular, with many branched fibres, almost black without, and white within, inodorous, and, when fresh, of a bitter, acrid, burning taste. By drying it loses much of its acrimony, and is said to be rendered edible by roasting. Hogs are said to root it up from the ground and to eat it with impunity; and hence its common French name. The root is a drastic cathartic, and is used to cause abortion, but has in such cases produced fatal gastro-enteritis. Its active principle appears to be *arthanitin* of Saladin, *cyclamin* of S. De Luca. This is a poisonous glucoside, which, when boiled with diluted acids, splits into *cyclamiretin*, $C_{15}H_{22}O_2$, and glucose. It is white, amorphous, inodorous, and, when held a short time in the mouth, intensely acrid, extending its action even to the throat. With cold water it swells and becomes gelatinous, but is readily dissolved, and forms a solution which froths like soap and water, and is coagulated by a heat of about 65·5° C. (150° F.). Alcohol dissolves it with difficulty when cold, but freely when hot; it is soluble in glycerin with the aid of heat; and is insoluble in ether, chloroform, disulphide of carbon, and the essential oils. Its formula, according to an analysis by Klinger, is $C_{20}H_{34}O_{10}$, although Kobert (*Chem. Centr.*, 1893, i. 32) makes it one of the class of saponins, and gives it the formula $C_{20}H_{32}O_{10}$, which is the same as that of sarsaparil-saponin and smilacin. Dr. T. W. C. Martius recommends the following method of preparing it. The tubers, collected in the autumn, dried and powdered, are mixed with animal charcoal, and exhausted at a boiling heat by alcohol of 0·825; the tincture is filtered, concentrated, and set aside for six or eight weeks, when the cyclamin is deposited. This should be washed on a filter with alcohol till it passes colorless; and if the filtrate be concentrated, and set aside, it will deposit a further quantity in a few weeks. The whole is then mixed with animal charcoal and treated with boiling alcohol, which

will slowly deposit the pure cyclamin on cooling. The dose of the powdered root is said to be from twenty to forty grains (1·29–2·59 Gm.).

CYDONIUM. *Quince Seed. Semen Cydoniæ*, P. G. *Semences (Pépins) de Coing, Semences de Coing*, Fr. *Quittenkerne, Quittensamen*, G. *Semi di Cotogno*, It. *Simiente de Membrillo*, Sp. The *Cydonia vulgaris*, Pers. (now *Pyrus Cydonia*, L.), or common quince-tree, is characterized as a species by its downy deciduous leaves. It is supposed to be a native of Crete, but grows wild in Austria, on the banks of the Danube. The fruit is about the size of a pear, yellow, downy, of an agreeable odor, and a rough, astringent, acidulous taste; and in each of its five cells contains from eight to fourteen seeds. Though not eaten raw, it forms a very pleasant confection; and a syrup prepared from it may be used as a grateful addition to drinks in sickness, especially in looseness of the bowels, which it is supposed to restrain by its astringency. The seeds, which were formerly official, are ovate, angled, reddish brown externally, white within, inodorous, and nearly insipid, being slightly bitter when long chewed. Their coriaceous envelope abounds in mucilage, which is extracted by boiling water. "About a quarter of an inch (6 Mm.) long, oval or oblong, triangularly compressed, brown, covered with a whitish, mucilaginous epithelium, causing the seeds of each cell to adhere. With water the seeds swell up, and form a mucilaginous mass. The unbroken seeds have an insipid taste." *U. S.* 1880. Two drachms of the seeds will render a pint of water thick and ropy. (*A. J. P.*, 1876, 35.) It has been proposed to evaporate the decoction to dryness, and powder the residue. Three grains of this powder form a sufficiently consistent mucilage with an ounce of water. According to M. Garot, one part communicates to a thousand parts of water a semi-syrupy consistence. (*Journ. de Pharm.*, 3e sér., iii. 298.) Dr. Pereira considers the mucilage as peculiar, and proposes to call it *cydonin*. It differs from arabin in not yielding a precipitate with potassium silicate, and from bassorin and cerasin in being soluble in water both hot and cold. Tollens and Kirchner (*Ann. d. Chimie*, clxxv. 205–226) assign to it the formula $C_{18}H_{28}O_{14}$, regarding it as a compound of gum, $C_{12}H_{20}O_{10}$, and cellulose, $C_6H_{10}O_5$, less one molecule of water. Quince mucilage is very bland, and may be used for the same purposes as other mucilaginous liquids. The U. S. P. 1880 gave the following formula for its preparation. "Cydonium, *two parts* [or thirty-six grains]; Distilled Water, *one hundred parts* [or four fluidounces]. Macerate the Cydonium for half an hour, in a covered vessel, with the Distilled Water, frequently agitating. Then drain the liquid through muslin, without pressure. This preparation should be freshly made, when required for use."

CYNANCHUM VINCETOXICUM. Pers. *Asclepias Vincetoxicum.* Linn. (Now *Vincetoxicum Officinale*, Moench.) *White Swallow-wort. Vincetoxicum. Dompte-venin, Hirundinaria*, Fr. *Schwalbenwurz, Giftwende*, G. A perennial, herbaceous European plant, the root of which was formerly esteemed a counterpoison, and hence the botanical name. It has a bitterish, acrid taste, and, when fresh, a disagreeable odor, which is diminished by drying. Taken internally, especially in the recent state, it excites vomiting, and is capable, in larger quantities, of producing dangerous if not fatal inflammation of the stomach. It is said to be useful in *cutaneous diseases* and *scrofula*. Feneulle found in the root a principle analogous to emetin.

CYNARA SCOLYMUS. L. (Now *C. Cardunculus.* L.) *Garden Artichoke.* This is a perennial composite plant, indigenous in the south of Europe, and cultivated as a culinary vegetable. The receptacle and the lower portion of the fleshy leaflets of the flower-heads are eaten. When young, the heads are cut up raw and eaten as salad; when older, they are boiled, and dressed variously. The flowers are said to curdle milk, and the plant to yield a good yellow dye. The leaves and their expressed juice are very bitter, and have been thought to be actively diuretic. They have been used in *dropsies* and *rheumatic affections*.

CYNOGLOSSUM OFFICINALE. L. *Hound's Tongue. Langue de Chien*, Fr. *Hundszunge*, G. A biennial plant of the nat. ord. Boraginaceæ, common both in Europe and in this country. The leaves and root have been employed, but the latter has been generally preferred. The fresh plant has a disagreeable narcotic odor, resembling that of mice, which is dissipated by drying. The taste is nauseous, bitterish, and mucilaginous. Different opinions as to its powers have been entertained, some considering it nearly inert, others as a dangerous poison. Diedülin, of St. Petersburg, Russia, affirms that an extract of this plant will paralyze the motor nerves in vertebrate animals; and J. Setschenow, of Grätz, states that, upon introducing a piece of the extract, about as large as the head of a pin, which he had received from Dr. Diedülin, into the dorsal lymph sac of each one of four frogs, he produced total paralysis of motion in from five to ten minutes; the heart continuing to beat, the irritability of the muscles continuing, and sensation remaining undisturbed. (See *Med. and Surg. Reporter*, 1868, 153.) Hound's tongue has been used as a demulcent and sedative in *coughs, catarrh, spitting of blood, dysentery*, and *diarrhœa*. The *pilulæ de cynoglosso* owe their properties chiefly to opium.

CYPERUS ARTICULATUS. *Adrue.* (Nat. ord. Cyperaceæ.) This *Guinea rush* is said to be largely used in its native country as an antiemetic and tonic. Dose, of fluid extract, thirty minims (1·85 C c.). (*New Mat. Med.*)

CYPRESS OIL. An oil derived from the *Cupressus sempervirens*, L. (nat. ord. Coniferæ), has been strongly recommended by Bravo in *whooping-cough;* it is used by sprinkling the clothes, bed, etc., about the patient.

CYTISUS LABURNUM. L. (Now *Laburnum vulgare.* Grisebach.) *Laburnum.* The laburnum is a small tree, indigenous in the higher mountains of Europe, and cultivated, throughout the civilized world, for its flowers, which appear early in the spring in rich pendent yellow clusters. All parts of the plant are probably poisonous. In fifty-eight boys poisoned simultaneously by the roots, the symptoms were intense sleepiness, vomiting, convulsive movements, coma, slight frothing at the mouth, and unequally dilated pupils. (*Med. Times and Gaz.*, vol. ii., 1875.) In some cases the diarrhœa has been severe. The convulsions have at times been markedly tetanic; wide-spread anæsthesia has been noted, and also excessive mydriasis, with loss of the pupillary reflex, elevation of temperature, delirium, and cyanosis. After death there have been found erosion of the colonic mucous

membrane, extreme hyperæmia of the brain, and nephritis. (*Deutsch. Med. Wochensch.*, xxi. 1895.) For cases, see also previous editions of the *U. S. D.*; *Arbeiten Pharm. Instit. Dorpat*, ii., 1888; *Le Mouvement Méd.*, 1875, No. 28; *Dub. Quart. Journ.*, 1863, 248; *Méd. Times and Gaz.*, Sept. 1862; *Lancet*, Aug. 1870.) Caventou found in the flowers an odorous fixed oil, gum, lignin, gallic acid, and traces of calcium sulphate and chloride. Chevallier and Lassaigne discovered in the seeds of *cytisus* a white, amorphous, deliquescent, non-nitrogenous substance, of a bitter nauseous taste, soluble in water and weak alcohol, and insoluble in ether. In small doses it produced, in animals, vomiting, convulsions, and death. (Mérat and De Lens.) Husemann and Marmé isolated in 1864 an alkaloid, *cytisine*, a white, crystalline solid, of a bitter somewhat caustic taste, soluble in water and alcohol, but scarcely at all soluble in ether, chloroform, benzol, or carbon disulphide. A second alkaloid, *laburnine*, was also announced by them. (*Chem. News*, July 16, 1869, 36.) Partheil (*Arch. der Pharm.*, 1892, 448) has since studied cytisine, and gives it the formula $C_{11}H_{14}N_2O$, which has been adopted by other authorities. He considers it to be identical with the *ulexine* of the *Ulex europœus*, L. (nat. ord. Leguminosæ). When cytisine is distilled with soda lime, a pyridine derivative is obtained, besides a base, $C_9H_{13}N$, which is possibly a hydroquinoline. Cytisine is stated to be found also in arnica flowers.

According to the researches of P. C. Plugge (*Archiv der Pharm.*, 1895), cytisine is a very widely distributed alkaloid. He has found it in eight species of the genus Cytisus, two of the genus Genista, two of the genus Sophora, two of the genus Baptisia, and in other plants. He asserts that *ulexine* of Gerrard, from *Ulex europœus*, L.; *sophorine* of H. C. Wood, from *Sophora speciosa*, Benth. (now *S. secundiflora*, Lag.), and *baptitoxine* of Von Schroeder, from *Baptisia tinctoria*, R. Br., are identical with cytisine. Prof. Plugge also believes that the alkaloid of *Euchresta horsfieldii*, Benn. (nat. ord. Leguminosæ), a Javanese pea, whose seeds are used as a contra-poison by the natives, is identical with cytisine. Kobert and Radziwillowicz (*loc. cit.*) find that in the lower animals the symptoms of poisoning by cytisine resemble somewhat those of strychnine-poisoning, but are attended by much vomiting of centric origin; that the alkaloid depresses even in the living organism ozonizing properties of the red corpuscles; that it first excites and afterwards paralyzes the centre of respiration, and probably in this way causes death; that it also powerfully stimulates the vaso-motor centres, producing a marked elevation of blood-pressure which is independent of the heart and is followed, if the dose have been large enough, by a gradual fall of pressure, due to paralysis of the vaso-motor centres. The motor side of the spinal cord is also strongly excited by small, and finally paralyzed by large, doses. The peripheral ends of the motor nerves are paralyzed in a curare-like method. The alkaloid also seems to have a distinct action upon the uterus, and has frequently produced abortion. Therapeutic trials were made with the alkaloid in hypodermic doses of 0·005 Gm., or by the mouth in from one- to three-drop doses of the 1 per cent. solution, in conditions of *depression*, without much effect. Dr. Gray (*Journ. de Pharm.*, 1862) found laburnum to produce in man narcotic effects, and commends it in *vomiting*, *bronchitis*, *whooping-cough*, and *asthma*.

DAMIANA. Under this name have been sold in the American market as aphrodisiacs several distinct Mexican drugs. According to Mr. Wellcome, there were in 1875 (*A. J. P.*, xlvii.) at least three of these, each claiming to be genuine.

Of these various drugs, one had a smooth, dark green, broadly lanceolate, dentate leaf, usually having six teeth on each side, heavy midrib, and ribs extending to the point of the teeth, from two to five lines in width and from six to twelve in length; the stem was red and woody, and the leaves gave a minty flavor when chewed. The second variety had a light green, obovate, deeply toothed leaf, having three and occasionally four teeth on each side, with a heavy midrib, and branching ribs extending to the edge. The surface was rough, and both sides were covered with short hairs. It was from two to five lines in width and five to eight in length. The stem was very woody, and near the apex it was quite hairy; on chewing it yielded a sage-like flavor. In the third variety the leaf was light green, lanceolate, having three teeth on each side, which terminated in hard, sharp points; it had a distinct midrib, and was rather indistinctly veined; was from one and a half to three lines in width and four to ten in length. It was quite thick and had a rough surface, with occasional black dots. To the naked eye the leaf appeared to be covered with shining scales, which, under the glass, appeared as minute resin-like globules. This was the only specimen accompanied by flowers. They were compound, with yellow florets and white pappus; the stem was woody, with green epidermis, and covered with resinous secretion. In 1882 there were two damianas in the Philadelphia market. One was chiefly composed of pieces of stems and branches, but contained enough of floral heads and leaves to show that it was the third variety of Wellcome, and was the product of one of the Compositæ, *Bigelowia veneta*, Gray (*Aplopappus discoideus*, De C.). (*Med. and Surg. Rep.*, xxxiv. 180.) The second variety was that considered by the introducers as *genuine damiana*. It was the leaves and terminal twigs of a Turnera (nat. ord. Turneraceæ), supposed by some to be a new species, *T. aphrodisiaca*, L. F. Ward (now *T. diffusa*, Willd.), but which is probably only a variety of *T. microphylla*, De C. It is this drug which constitutes the damiana of commerce. The leaves are from three to eight lines long, one to three lines broad, obovate to lanceolate, eight to ten sharp-toothed, smooth or with a few hairs on ribs below, midrib marked with, in some cases, strong, straight veins running to the edge between the teeth; in other cases veins branched and sending a final vein into the tooth; stems fine, woody, reddish, ends of branches hairy. F. W. Rantzer (*A. J. P.*, 1887, 69) obtained from the leaves of *Turnera aphrodisiaca* about one-half per cent. of an amber-colored volatile oil, with a heavy aromatic odor, and a warm, camphoraceous, and bitter taste; also tannin, two tasteless resins, and extractive.

The published reports as to the value of the drug vary greatly, some having had great success with it in *sexual atony*, most finding it useless; it is probably nothing more than a feeble tonic. An ounce (31·1 Gm.) of the leaves, either in the form of infusion or fluid extract, may be given daily.

DANAIS FRAGRANS. Gaertn. f. (Nat. ord. Rubiaceæ.) In this Madagascar plant, whose root is said to be tonic and antiperiodic, Heckel and Schlagdenhauffen found a glucoside, *danain.* (*A. J. P.*, 1886.)

DAPHNANDRA. The bark of several species of Australian trees belonging to the genus Daphnandra (nat. ord. Monimiaceæ) is asserted to be rich in poisonous alkaloids. (*P. J. Tr.*, Oct. 1887.) Dr. Bancroft states that the active alkaloid is soluble in water, and to some extent is antagonistic to strychnine.

DELPHINIUM. It is probable that most if not all of the species of this genus of Ranunculaceæ are actively poisonous. Rochebrune (*Toxicol. Africaine*, i.) has separated alkaloids believed by him to be identical with *delphinine* from the *D. peregrinum*, L., and *D. mauritanicum*, Coss.; whilst Thomas C. Hopkins, of Baltimore, found in the seeds of the *D. consolida*, L., or *Larkspur* (*Lark's claw*, *Knight's spur*), *delphinine* ($C_{24}H_{35}NO_2$), volatile oil, fixed oil, gum, resin, chlorophyll, gallic acid, and salts of potassa, lime, and iron. (*A. J. P.*, xi.) From the expressed juice of the larkspur *aconitic acid* was obtained by W. Wicke (*Journ. de Pharm.*, 1854.) Moreover, the seeds of the indigenous *D. exaltatum*, Art. (now *D. urceolatum*, Jacq.), are stated to have a similar physiological action with those of the larkspur. The larkspur (*D. consolida*) is a showy annual, whose leaves are divided into linear segments, widely separated, and forked at the summit. The flowers are usually of a beautiful azure-blue color, and disposed in loose terminal racemes, with peduncles longer than the bracts. The nectary is one-leaved, with an ascending horn nearly equalling the corolla. The seeds are contained in smooth, solitary capsules. The species has been introduced from Europe into the United States, where it has become naturalized, growing in the woods and fields, and flowering in June and July. The flowers are bitter and acrid. In large doses the seeds produce violent vomiting and purging, and are said also to be diuretic. They were formerly in the Secondary List of the U. S. Pharmacopœia, and a tincture (℥i to Oi diluted alcohol) has been used in spasmodic *asthma* and *dropsy*; dose, ten drops (0·6 C.c.) gradually increased. Mr. Brett has found that *D. peregrinum*, L., when growing is very effective in the destruction of grasshoppers. (*P. J. Tr.*, vol. xxi., 1891.)

DERMATOL. (See *Bismuthi Gallas.*)

DERMOL is said to be obtained by treating bismuth oxide with chrysophanic acid. It is used principally in ointment for skin diseases.

DIABETIN is a proprietary saccharine body nearly identical with levulose. It is intended for the use of diabetic patients.

DIALYSIS. This name was given by the late Prof. Graham, Master of the Mint, London, to a process based upon the different diffusibility of liquids, by which mixed substances may often be separated from each other. For a brief history, see p. 1781. *U. S. D.*, 16th edition.

DIANTHUS CARYOPHYLLUS. L. *Clove Pink.* (Nat. ord. Caryophyllaceæ.) Of the ordinary garden pink those specimens should be selected for medicinal use which have the deepest red color and the most aromatic odor. The petals should not be collected till the flower is fully blown, and should be employed in the recent state. They have a fragrant odor, thought to resemble that of the clove. Their taste is sweetish, slightly bitter, and somewhat astringent. Both water and alcohol extract their sensible properties, and they yield a fragrant essential oil by distillation. In Europe they are employed to impart color and flavor to a *syrup*, used as a vehicle. The Edinburgh Pharmacopœia directed this to be made by macerating one part of the flowers, without their claws, in four parts of boiling water for twelve hours, then filtering, and adding seven parts of sugar.

DIAPHORETIC ANTIMONY. *Antimonium Diaphoreticum. Potassii Biantimonias.* This compound is directed, in the French Codex, to be formed by deflagrating in a red-hot crucible, and keeping red-hot for half an hour, a mixture of pure antimony with twice its weight of potassium nitrate, both being in fine powder. The product, washed with water and dried, is *washed diaphoretic antimony.* For improved process, see 14th edition of *U. S. D.*, p. 1640. Dose, from two to three drachms (7·77–11·66 Gm.). Weak, variable, rarely used.

DIAPHTHOL. *Quinaseptol. Orthoxyquinoline-metasulphonic Acid.* Occurs in yellowish-white crystals slowly soluble in cold water. It is an antiferment said to be without toxicity.

DICTAMNUS ALBUS. L. *White Fraxinella. Bastard Dittany.* (Nat. ord. Rutaceæ.) The aromatic bitter bark of the root of this European plant was formerly used. Störck gave it in *intermittents*, *worms*, *amenorrhœa*, *hysteria*, and *epilepsy.* Dose, from a scruple to a drachm (1·29–3·88 Gm.).

DIDYMII NITRAS. *Didymium Nitrate.* $Di_2(NO_3)_6\ 12H_2O$. This salt occurs in rose-colored crystals soluble in water and alcohol. It has been used as an antiseptic, preventing the growth of bacteria when used in solutions of the strength of 1 in 2000. (*Centralb. Bact. und Parasiten*, xxi.)

DIERVILLA TRIFIDA. Moench. *D. Canadensis.* Muhl. *D. Diervilla.* (L.) MacM. *Bush Honeysuckle.* A low, erect, indigenous shrub, growing especially in rocky places throughout the Northern States. The whole plant is supposed to be possessed of diuretic and astringent properties, and is given in infusion by the "eclectics" in diseases of the urinary passages.

DI-ETHYL-KETONE. *Propione*, $C_2H_5.CO.C_2H_5$, is obtained by the dry distillation of *calcium propionate*, $(C_3H_5O_2)_2Ca$. A transparent liquid, soluble in twenty-four parts of water, mixing with water, alcohol, and ether, boiling at 101° C.; recommended by Albanese and Barabini in 1892 as inducing sleep in animals. It has been used by Giovanni in the treatment of *maniacal* and *hysterical excitement* in doses of from eight to twenty grains (0·5–1·3 Gm.). It should be administered in dilute solution.

DINITROCRESOL. $C_6H_2(NO_2)_2\left\{\begin{matrix}CH_3\\OH\end{matrix}\right.$.

Commercial *Saffron Substitute* is a mixture of the potassium salts of dinitro-ortho- and para-cresols. It is said to have been sold for saffron in Berlin, with fatal results. (*Rundschau*, Prague, 1887.)

DIONINE. *Hydrochlorate of mono-ethyl-ester of morphine.* This substance is a white, somewhat bitter, micro-crystalline powder, soluble in seven parts of water, one and a half parts of alcohol, and twenty parts of syrup; insoluble in ether and chloroform; precipitated from its solutions by most of the alkaloidal reagents. It was first brought forward by Ludwig Hesse (*Pharm. Centralb.*, xl.) It

has been studied therapeutically by Schroder and Korte and by Von Mering. Its action is said to be very similar to that of codeine, but somewhat stronger and more prolonged. It appears not to be comparable with morphine as an analgesic, but to be of especial service in quieting cough. It is said to increase rather than decrease expectoration in *phthisis* and other pulmonic affections, and to be of especial value in the lessening of night-sweats. The dose is from one-sixth to one-fourth of a grain (0·012–0·016 Gm.) every four or five hours, or a single dose of half a grain (0·032 Gm.) at bedtime.

DIOSCOREA VILLOSA. L. *Wild Yam-root. Colic-root. Rheumatism-root.* (Nat. ord. Dioscoreaceæ.) An indigenous perennial creeper, with long, branching, contorted, fibrous, ligneous roots. It grows from Ontario to Wisconsin, and south to Florida and Texas. For an excellent illustrated microscopical description of the plant, by Prof. E. S. Bastin, see *West. Drug.*, 1885, 203. The roots are used by the "eclectics," who consider them efficacious in *bilious colic*, and by the Southern negroes in *rheumatism*. W. C. Kalteyer found saponin in it in considerable quantity. (*A. J. P.*, 1888.) A substance, improperly called *dioscorein*, obtained by precipitating the tincture with water, is used in a dose of from one to four grains (0·064–0·259 Gm.). Dose, from four to eight fluidounces (118·2–236·5 C.c.) of decoction (℥i–Oi); ten minims to one fluidrachm (0·62–3·69 C.c.) of fluid extract.

Dioscorea hirsuta, Bl., grows in the island of Java, where it is known as *Gadoeng*. In 1894 W. G. Boorsma (*Mededeelingen uit's Lands Plantentuin*, xiii.) separated from it an alkaloid to which he gave the name of *dioscorine*. This alkaloid has been elaborately studied chemically and physiologically by Plugge and Schutte (*Arch. Internat. d. Pharmacod.*, iv., 1897), who obtained it in crystals having the formula $C_{13}H_{19}NO_2$, and found it to be a convulsant poison, resembling closely in its action picrotoxin, but much more feeble. *Dioscorea bulbifera*, L., grows in the Gaboon country of tropical Africa. Heckel and Schlagdenhauffen found in the tuber a glucoside, together with wax, chlorophyll, saccharose, and resin.

DIOSPYROS. *Persimmon. Date-plum. Fruits de Plaqueminier de Virginie*, Fr. *Persimmonfrüchte, Dattelpflaumen*, G. The *Diospyros Virginiana*, L. (nat. ord. Ebenaceæ), or persimmon, is an indigenous tree, rising sometimes in the Southern States to the height of sixty feet, with a trunk twenty inches in diameter; but seldom attaining more than half that size near its northern limits, and often not higher than fifteen or twenty feet. The stem is straight, and in the old tree covered with a furrowed blackish bark. The branches are spreading; the leaves ovate-oblong, acuminate, entire, smooth, reticulately veined, alternate, and supported on pubescent footstalks. The buds are smooth. The male and female flowers are on separate trees. They are lateral, axillary, solitary, nearly sessile, of a pale orange color, and not conspicuous. The fruit is a globular berry, dark yellow when ripe, and containing numerous seeds in a soft yellow pulp. The dried, roasted, and ground seeds are used in some parts of Georgia as a substitute for coffee. (*Med. and Surg. Reporter*, 1873, 437.)

This tree is very common in the Middle and Southern States, but, according to Michaux, does not flourish beyond the forty-second degree of north latitude. The flowers appear in May or June; but the fruit is not ripe till the middle of autumn. While green, the fruit is excessively astringent, and in this form was formerly included in the U. S. Secondary List; but, when perfectly mature, and after being touched by the frost, it is sweet and palatable. The unripe fruit, according to Mr. B. R. Smith, of Philadelphia, contains tannic acid, sugar, malic acid, coloring matter, and lignin. (*A. J. P.*, xviii. 167.) The tannic acid was considered by Mr. John E. Bryan not to be of the kind existing in galls and oak-bark. (*Ibid.*, xxxii. 215.) Charropin (*Pharmacographia*, 403), however, believes the tannic acid to be identical with that of nutgalls, and finds besides an abundance of pectin, glucose, and a yellow coloring matter insoluble in water, but dissolving freely in ether. Wm. Schleif, Jr. (*A. J. P.*, 1890, 390), has extracted from persimmon-bark a resinoid principle, in the form of crystalline masses, soft and waxy when freshly crystallized from alcohol or ether, drying to a brownish mass of peculiar odor and slightly astringent taste, soluble in alcohol, ether, chloroform, very slightly in water. Heated to 258° C. it darkens considerably, and is decomposed at 262° C. The persimmon has been used by Mettauer in *diarrhœa, chronic dysentery*, and *uterine hemorrhage*. The dose of the vinous tincture (an ounce of the fresh green fruit to two fluidounces of dilute alcohol) is a fluidrachm (3·69 C.c.) or more for infants, and half a fluidounce (14·7 C.c.) or more for adults. The bark is astringent and very bitter.

DIOXYNAPHTHALENE ($C_{10}H_8O_2$) may exist in several modifications, the best known being the *α-* and *β-hydronaphthoquinones*. They are diatomic phenols in character. Lépine (*La Semaine Méd.*, No. 31, 1887) finds that dioxynaphthalene produces in dogs and guinea-pigs violent convulsions, alteration in the color of the blood, due to the formation of methæmoglobin, and blackening of the urine. He asserts that in asthenic persons three grains (0·194 Gm.) a day increase power.

DIPPEL'S ANIMAL OIL. *Oleum Cornu Cervi.* This oil was formerly produced in the process of obtaining ammoniacal products from bone or horn. (See early editions of *U. S. D.*)

DIRCA PALUSTRIS. L. *Leather Wood.* (Nat. ord. Thymelaceæ.) An indigenous shrub, usually very small, but sometimes attaining the height of five or six feet, growing in boggy woods, and other low wet places, in almost all parts of the United States. The berries, which are small, oval, and of an orange color, are said to be narcotic and poisonous. The tough bark, in the fresh state, has a peculiar rather nauseous odor, and an unpleasant acrid taste, and when chewed excites a flow of saliva. It yields its acrimony completely to alcohol, but imperfectly to water even by decoction. Six or eight grains of the fresh bark produce violent vomiting, preceded by a sense of heat in the stomach, and often followed by purging. Applied to the skin it slowly excites redness and ultimately vesicates. It is analogous to mezereon in its medical as well as botanical characters.

DITA. *Ecorce de Dita*, Fr. *Ditarinde*, G. This is the bark of a tree, *Alstonia Scholaris*, R. Br. (*Echites Scholaris*, L.), belonging to the family of Apocynaceæ, and growing in the Philippine Islands. It occurs in pieces from three to six

inches long and three to four lines thick, sometimes flat, sometimes slightly curved; its internal surface is fibrous and of a brown sepia tint; its section has the color of leather, and its external surface is of the same tint, with brown spots. It is compact, but readily pulverized; is without odor, and has a taste at first slight, afterwards decidedly bitter. M. Gruppe extracted from it, by a process similar to that used for quinine, an uncrystallizable, hygroscopic, bitter principle, *ditaine*. (*Journ. de Pharm.*, 4e sér., xviii. 225; xix. 84; *P. J. Tr.*, Aug. 1875.) Harnack (*Ber. Chem. Ges.*, 1878) first obtained ditaine in pure crystallized form, and gave it the formula $C_{20}H_{30}N_2O_4$. According to Erich Harnack (*Ditaine*, Leipsic, 1877), *ditaine* in the frog acts as a paralyzant upon the motor nerve-centres and the motor nerve-trunks, and also upon the vagi. Upon mammals its influence resembles closely that of curare. The peripheral nerve-endings are paralyzed by it, as are also the peripheral vagi and the vaso-motor nerves. O. Hesse (*P. J. Tr.*, Oct. 23, 1880) finds in dita the following principles. Three alkaloids: *ditamine*, $C_{16}H_{19}NO_2$, the relative amount of which he estimates at 0·04 per cent.; *echitamine*, $C_{22}H_{28}N_2O_4 + H_2O$ (identical, according to Hesse, with Harnack's ditaine); and *echitenine*, $C_{20}H_{27}NO_4$. Of these, the second is the strongest base, and resembles ammonia in its chemical characters. Hesse considers the compound given above with one molecule of water as the hydroxide of a strong basic radical, *echitammonium*, $C_{22}H_{29}N_2O_4$. The solutions of *echitammonium hydroxide* are so strongly basic that they precipitate the hydrates of copper, iron, aluminum, and lead, and decompose sodium and potassium chlorides, liberating the corresponding hydrates. Hesse considers echitammonium the most strongly basic of all the alkaloids. Hesse also obtained by extraction with petroleum benzin *echicaoutchin*, *echiretin*, *echicerin*, *echitin*, and *echitein*, of which the three last mentioned are crystalline. (See *A. J. P.*, 1895, 166.) Dita bark has been used as a tonic and in *dysentery*. Dose, of fluid extract, from eight to ten minims (0·5–0·61 C.c.). For microscopic characters, see *Newer Mat. Med.*

DITANA DIGITIFOLIA. This alleged medical plant seems to be a myth. (H. H. Rusby, *T. G.*, iii. 588.)

DITHIO-CALCIUM CARBONATE. *Dithiocarbonate of lime.* $CaCOS_2$. This orange-red crystalline, hygroscopic powder, slightly soluble in water, less so in alcohol, has been especially employed by Tommasoli and Vicini (*Monatssch. f. Prakt. Dermatol.*, 1892) as a local application in *eczema*, *psoriasis*, *lupus*, *purulent venereal* and other *skin diseases*, in the form of a 5 per cent. salve or a somewhat stronger aqueous solution. A 20 per cent. solution produced distinct burning irritation and even pustulation. Sabbatini states that the 1 per cent. solution inhibits, but does not kill pyogenic micro-organisms. On exposure, its aqueous solution undergoes decomposition with the separation of sulphur and hydrogen sulphide.

DITHION. *Sodium Dithio-salicylicum.* An energetic antiseptic for wounds, it is used in the form of a solution, powder, or ointment.

DITHIO-SALICYLIC ACID. $\begin{matrix}C_6H_3(OH)COOH.S\\C_6H_3(OH)COOH.S\end{matrix}>$. According to *Oest. Zeitsch. f. Pharm.* (1889, 298), dithio-salicylic acid, a proposed substitute for salicylic acid, is made by heating equal molecules of *sulphur chloride* and salicylic acid to from 120°–150° C., dissolving the light yellow fusion in sodium hydrate, and precipitating the acid, by addition of HCl, as a resinous straw-colored mass, forming, after pulverization, a light yellow powder, easily soluble in alcohol, benzol, and glacial acetic acid. The sodium salt of the acid, *Sodium dithio-salicylate*, is said by Lindenborn (*Rép. de Pharm.*, Sept. 1889) to be preferable in the treatment of *rheumatism* to salicylic acid, because more energetic and less apt to disturb the digestion. It is asserted that, as an antiseptic, it is fully equal to *sodium salicylate*. Dose, three grains (0·194 Gm.), repeated according to circumstances. Ten grains (0·647 Gm.) are said to produce nausea, tinnitus aurium, and sweating.

DOUNDAKÉ. *Quinquina Africaine. Kina du Rio Nunez.* The *Sarcocephalus esculentus*, Afzel (nat. ord. Rubiaceæ), of Africa yields a bark which is said to be an astringent and tonic febrifuge. For a description of the bark and its chemical characteristics, see *P. J. Tr.*, vol. xvi. 49. Heckel and Schlagdenhauffen do not believe that doundaké contains an alkaloid, but attribute its power to three distinct principles of a resinous nature, the first of which is of an orange-yellow color and very bitter, soluble in water, alcohol, and potash; the second light yellow in color, soluble in potash but not in water; the third soluble in potash, insoluble in water and in alcohol. (*Journ. Soc. Chem. Indus.*, 1886, 435.)

DRACONTIUM. *Skunk Cabbage. Skunk Weed. Polecat Weed. Racine de Pothos fétide*, Fr. *Stinkende Drachenwurzel*, G. *Symplocarpus fœtidus.* Nutt. *Dracontium fœtidum.* L. *Ictodes fœtidus.* Bigelow. *Spathyema fœtida.* (L.) Raf. The rhizome is perennial, large, abrupt, and furnished with numerous fleshy fibres, which penetrate to the depth of two feet or more. The spathe, which is the first part of the plant to appear, is ovate, acuminate, obliquely depressed at the apex, auriculated at the base, folded inward at the edges, and of a brownish-purple color, varied with spots of red, yellow, and green. Within the spathe, the flowers, which resemble it in color, are placed in great numbers upon a globose peduncled spadix, for which they form a compact covering. After the spathe has decayed, the spadix continues to grow, and when the fruit is mature, has attained a size exceeding several times its original dimensions. At the base of each style is a roundish seed about the size of a pea, immersed in the spadix, and speckled with purple and yellow. The leaves, which appear after the flowers, are numerous and crowded, oblong-cordate, acute, smooth, strongly veined, and attached to the rhizome by long petioles, which are hollowed in front, and furnished with colored sheathing stipules. At the beginning of May, when the leaves are fully developed, they are very large, being from one to two feet in length, and from nine inches to a foot in breadth. The plant is abundant in wet places throughout the northern and middle sections of the Union. Its flowers appear in March and April, and in the lower latitudes often so early as February. The fruit is usually quite ripe and the leaves are decayed before the end of August. All parts of it have a fetid odor, dependent upon an extremely volatile principle, which is rapidly dissipated by heat. The rhizome should be collected in autumn, or in early spring, and dried with care.

The rhizome occurs either whole or in transverse slices. When entire, it is cylindrical or in the shape of a truncated cone, two or three inches long by about an inch in thickness, externally dark brown and very rough from the insertion of the radicles, internally white and amylaceous. The rootlets are of various lengths, about as thick as a hen's quill, very much flattened and wrinkled, white within, and covered by a yellowish or red-dish-brown epidermis, considerably lighter colored than the body of the rhizome. The odor is fetid, the taste acrid; both are lessened by drying and progressively diminish with time, so that the dried rhizome should not be kept longer than a single season. This acrimony is entirely absent in the decoction. The radicles are said to have less acrimony than the caudex. The seeds are very acrid, and, though inodorous when whole, give out, when bruised, the peculiar odor of the plant.

The rhizome is affirmed to be antispasmodic and narcotic; occasioning nausea and vomiting, with headache, vertigo, and dimness of vision. It has been used with alleged success in *asthma*, *chronic catarrh*, *chronic rheumatism*, *chorea*, *hysteria*, and *dropsy*. Dose of powder, from ten to twenty grains (0·647–1·29 Gm.), increased till some evidence of action is afforded.

DRAGON'S BLOOD. *Sanguis Draconis. Sang-dragon*, Fr. *Drachenblut*, G. This is a resinous substance obtained from the fruit of several species of *Calamus*, especially *C. Rotang*, L., and *C. Draco*, Willd. (now *Dæmonorops Draco*, Blume), small palms, growing in Siam, the Moluccа Islands, and other parts of the East Indies. On the surface of the fruit, when ripe, is an exudation, which is separated by rubbing, or shaking in a bag, or by exposure to the vapor of boiling water, or finally by decoction. The finest resin is procured by the two former methods. It comes in two forms: sometimes in small *oval masses*, of a size varying from that of a hazelnut to that of a walnut, covered with the leaves of the plant, and connected in a row like beads in a necklace; sometimes in *cylindrical sticks*, eighteen inches long and from a quarter to half an inch in diameter, thickly covered with palm leaves, and bound round with slender strips of cane. In both these forms it is of a dark reddish-brown color, opaque, and readily pulverizable, affording a fine scarlet powder. It sometimes comes also in the form of a reddish powder, and in small irregular fragments or tears. An inferior kind, said to be obtained by boiling the fruit in water, is in *flat circular cakes*, two or three inches in diameter and half an inch thick. This also yields a fine red powder. A fourth variety, much inferior even to the last mentioned, is in *large disks*, from six to twelve inches in diameter by an inch in thickness, mixed with various impurities, as pieces of the shell, stem, etc., and supposed to be derived from the fruit.

According to the British Resident at Pontianak (1891), dragon's blood is sent into commerce from Pontianak, first, in flat cakes of various dimensions; second, in small cakes from three to seven inches long and an inch wide; third, in long pipes; whilst the regular cakes of dragon's blood, three inches wide, three inches long, and a quarter-inch thick, are manufactured at Singapore. One substance known by the name of dragon's blood is derived by exudation from the trunk of *Dracæna Draco*, L. (nat. ord. Liliaceæ), a large tree inhabiting the Canary Islands and the East Indies, and another from *Pterocarpus Draco*, L. (nat. ord. Leguminosæ), a tree of the West Indies and South America, by incision into the bark: these, however, are little known in commerce. *Drop Dragon's Blood* is the product of the *Dracæna schizantha*, Baker (nat. ord. Liliaceæ), of Socotra. It is occasionally seen in the London market. It is in small tears and fragments, seldom exceeding an inch in length, has a clean glassy fracture, and in thin pieces is transparent and of a splendid ruby color. It may be distinguished from true dragon's blood by the absence of shell-like scales, and by not evolving the irritating fumes of benzoic acid when heated.

Dragon's blood is inodorous and tasteless, insoluble in water, but soluble in alcohol, ether, and the volatile and fixed oils, with which it forms red solutions. According to Herberger, it consists of 90·7 parts of a red resin, which he calls *draconin*, 2·0 of fixed oil, 3·0 of benzoic acid, 1·6 of calcium oxalate, and 3·7 of calcium phosphate. Johnston (*Journ. Pract. Chem.*, xxvi. 145) gives the formula $C_{10}H_{10}O_2$ to the resin, while Dobbie and Henderson (*A. J. P.*, 1884, 327) give $C_{18}H_{18}O_4$ as the formula of the same. By distilling the resin, *toluene*, $C_6H_5CH_3$, and *styrene*, C_8H_8, have been obtained. *Cinnamic acid* has also been noted by Hirschsohn. By distillation with caustic potash, it yields *phloroglucin protocatechuic acid*, and *paraoxybenzoic* and *oxalic acids* (*Pharmacographia*, 674). It was formerly employed in medicine as an astringent, but is nearly or quite inert, and is now never given internally. It is sometimes used to impart color to plasters, but is valued chiefly as an ingredient of paints and varnishes.

Messrs. Dobbie and Henderson have found that the dragon's blood resins are chemically of several varieties. (See *Journ. Chem. Soc.*, April, 1884, or *A. J. P.*, 1884, 327.)

DROSERA. *Sundews. Herba Rorellæ. Rossolis. Rosée du Soleil*, Fr. *Sonnenthau*, G. *D. rotundifolia*, L., and *D. longifolia*, L. (nat. ord. Droseraceæ), are said to be useful in *phthisis*, but they are probably of no value. (See *Proc. A. P A*, xxvii. 225.)

DUBOISIA. *D. myoporoides*, R. Br. (nat ord. Solanaceæ), is a tall, glabrous shrub or small tree, with alternate obovate-oblong or oblong-lanceolate entire leaves, which are from two to four inches long, about an inch wide, and contracted into the petiole. The small flowers are of a white or pale lilac color, arranged in terminal panicles. The berry is nearly globular. The tree is a native of Australia, and has been found in New South Wales, New Caledonia, and Queensland. The medical properties of the leaves of this plant were made known by Baron von Mueller, who received them from Dr. J. Bancroft, with the statement that they would be found to act like stramonium leaves. The alkaloid *duboisine* was discovered in the leaves by A. W. Gerrard (*P. J. Tr.*, viii. 787). For his method, see 16th ed. *U. S. D.*; also, for an account of the chemical and medicinal properties of this alkaloid, and its relations to atropine and hyoscyamine, see *Belladonna*, in PART I.

According to the researches of Jos. Lanterer (*Lancet*, 1896), the old leaves and twigs of *Duboisia myoporoides*, R. Br., contain hyoscyamine, the fresh young leaves scopolamine, the dried leaves being stronger than are belladonna leaves, and yielding 0·97 per cent. of alkaloid. *Duboisia leich-*

hardtii, F. Muell., is said to be still richer in alkaloid which is chiefly amorphous scopolamine; whilst the leaves of *Brugmansia arborea*, Stend. (now *Datura arborea*, L.), and *B. knightii*, Hort. (now *Datura cornigera*, Hook.), natives of South America acclimatized in Queensland, contain a mixture of hyoscyamine and atropine.

D. Hopwoodii, F. Muell., is the source of *Pituri*, a narcotic stimulant largely used by the natives of Central Australia. The drug itself is a fine powder, composed of the leaves and twigs which are gathered during the month of August, while the flower is in bloom, and are put up in various forms of circular mats about six inches in diameter. The natives smoke and chew the pituri, and it is alleged to have a powerful stimulating effect, assuaging hunger, and enabling those who are its devotees to perform much labor and go long journeys with but little food. Pituri yielded to Mr. A. W. Gerrard minute quantities of an alkaloid which he believed to be identical with nicotine, but Prof. Liversidge has shown that the liquid, acrid alkaloid, *piturine*, $C_{12}H_{16}N_2$, is distinct from nicotine. (*Proc. Roy. Soc. N. S. Wales*, 1880.) The pituri contains from 1 to 2½ per cent. of the alkaloid.

EGGS. The egg of the ordinary hen consists of an exterior covering, the shell; a white, semi-opaque membrane, lining the internal surface of the shell; the white; and the yolk.

The shell—*testa ovi* or *putamen ovi*—consists, according to Vauquelin, chiefly of calcium carbonate, with animal matter, and a minute proportion of calcium phosphate, magnesium carbonate, ferric oxide, and sulphur. When exposed to a high degree of heat in the open air, the carbonic acid is driven off, the animal matter consumed, and the lime left nearly pure. The membrane lining the shell appears to be of an albuminous nature. The white—*ovi albumen*, Br. 1883—is a glairy viscid liquid, contained in very delicate membranes, without odor or taste, readily soluble in water, coagulable by the stronger acids, by alcohol, and by a heat of 56° C. (132·8° F.). Exposed in thin layers to a current of air, it becomes solid, retaining its transparency and solubility in water. By coagulation it is rendered sapid, white, opaque, and insoluble. At a temperature of 100° C. (212° F.), one part of it renders one thousand parts of water in which it has been dissolved opaque. It contains, according to Dr. Bostock, in 100 parts, 85 of water, 12 of pure albumen, 2·7 of mucus or uncoagulable matter, and 0·3 of saline substances, including soda with traces of sulphur. The white of egg is precipitated by stannous chloride, gold chloride, lead subacetate, copper sulphate, corrosive sublimate, and tannin. When kept in the fluid state it soon putrefies; but if carefully dried without coagulation it may be long preserved unaltered, and may be applied in solution to the same purposes as in its original condition.

The yolk—*ovi vitellus*, Br. 1883—is inodorous, of a bland oily taste, and forms an opaque emulsion when agitated with water. By heat it is coagulated into a granular solid, which yields a fixed oil by expression. The researches by Gobley and others have established the constitution of the yolk about as follows: water, 51·8 per cent.; vitellin, 15·8 per cent.; nuclein, 1·5 per cent.; palmitin, stearin, and olein, 20·3 per cent.; cholesterin, 0·4 per cent.; phosphoglyceric acid, 1·2 per cent.; lecithin, 7·2 per cent.; cerebrin, 0·3 per cent.; coloring matter, 0·5 per cent.; salts, 1·0 per cent. (König, *Nahrungs- und Genussmittel*, 180.) Vitellin belongs to the class of globulins, and, while not precipitated from its solution by sodium chloride, is precipitated completely on saturation of its solution with ammonium sulphate. Chevreul states that there are two coloring principles, one reddish containing iron, the other yellow and similar to the coloring matter of bile. The former is more difficultly soluble in ether than the latter. (*Neues Repert.*, 1867, xvi. 697.) It is said that the yolk may be kept for a considerable time without observable change by adding to it 5 per cent. of sodium sulphate, in powder or concentrated solution. Granules have been found, with the aid of the microscope, in the yellow of the egg, which are rendered blue by iodine, and have all the other properties of the starch granules. (*Journ. de Pharm.*, Oct. 1868, 261.)

Eggs are applied to various purposes in medicine and pharmacy. The shells, powdered and levigated, have been used as an antacid in *diarrhœa*, in doses of from five to ten grains (0·33–0·65 Gm.).

The *white* of egg is used chiefly for the clarification of liquids, which it effects by involving, during its coagulation, the undissolved particles, and rising with them to the surface, or subsiding. It is highly recommended as an antidote for corrosive sublimate and copper sulphate, with which it forms insoluble and comparatively inert compounds. It is sometimes also used for the suspension of insoluble substances in water, but is inferior for this purpose to the yolk, and even to mucilage of gum arabic. Agitated briskly with a lump of alum, it coagulates, at the same time dissolving a portion of the alum, and thus forming the so-called *alum curd*, which is used between folds of gauze over the eye, in some states of *ophthalmia*. It is also used in the official pepsin valuation.

The *yolk* in its raw state is thought to be laxative. In pharmacy, the yolk is highly useful as an intermedium between water and insoluble substances, and is to be preferred to the white in preparing emulsions.

ELEMI. *Gum Elemi.* The botanical source of this concrete resinous exudation is not positively determined, and it is, indeed, probable that the drug usually known by the name of *elemi* is derived from several different trees. That known to the ancients is said to have been obtained from Ethiopia, and all the elemi of commerce was originally brought from the Levant. The tree which afforded it was not accurately known, but was supposed to be a species of Amyris. At present the drug is said to be derived from three sources,—namely, Brazil, Mexico, and Manila. The Brazilian is believed to be the product of a plant mentioned by Marcgrav under the name of *icicariba*, and called by De Candolle *Icica icicariba* (now *Protium icicariba* (D.C.), L., March), of the nat. ord. Burseraceæ. It is a lofty tree, with pinnate leaves, consisting of three or five pointed, perforated leaflets, smooth on their upper surface and woolly beneath. It is erroneously stated in some works to be a native of Carolina. The elemi is obtained by incisions into the trees, through which the juice flows and concretes upon the bark. The Mexican is said by Dr. Royle to be obtained from a species of Elaphrium, which that author has described from dried specimens and proposes to name *E. elemiferum*. (*Mat. Med.*, Am. ed., 339.)

The Manila elemi is conjecturally referred to *Canarium commune* (L.). (*Ibid.*, 340.)

Elemi is in masses of various consistence, sometimes solid and heavy like wax, sometimes light and porous; unctuous to the touch; diaphanous; of diversified colors, generally greenish with intermingled points of white or yellow, sometimes greenish white with brown stains, sometimes yellow like sulphur; fragile and friable when cold; softening by the heat of the hand; of a terebinthinate somewhat aromatic odor, diminishing with age, and resembling to some extent that of lemon and fennel; of a warm, slightly bitter, disagreeable taste; entirely soluble, with the exception of impurities, in boiling alcohol; and affording a volatile oil by distillation. "Moistened with rectified spirit, it breaks up into small particles, which, when examined by the microscope, are seen partly to consist of acicular crystals." *Br.*, 1885. A variety examined by M. Bonastre was found to consist of 60 parts of resin, 24 of a resinous matter soluble in boiling alcohol, but deposited when the liquid cools, 12·5 of volatile oil, 2 of extractive, and 1·5 of acid and impurities. M. Baup found the resin to be of two kinds, one amorphous, the other crystallizable; the latter of which, as obtained from West India elemi, he proposes to call *elemin*, and considers identical with the crystallizable resin *amyrin*, obtained from Manila elemi. (*Journ. de Pharm.*, 3e sér., xx. 331.) Elemi is sometimes adulterated with colophony and turpentine. Dr. Emil Mannkoff obtained from Brazilian elemi about 6 per cent. of a colorless volatile oil, insoluble in water, but easily dissolved both by alcohol and ether, of a not unpleasant odor, and a somewhat acrid and bitter taste. (*B. and F. Medico-Chir. Rev.*, July, 1859, 170.) Prof. Flückiger obtained as much as 10 per cent. of essential oil from Manila elemi. He found it to be a fragrant, colorless, neutral oil, of sp. gr. 0·861 at 15° C. (59° F.), and strongly dextrogyrate. Deville, on the other hand, obtained an oil equally strongly lævogyrate. Flückiger thus sums up the constituents of elemi: essential oil, $C_{10}H_{16}$; *amyrin*, $3(C_{10}H_{16}) + H_2O$; amorphous resin, $2(C_{10}H_{16}) + 2H_2O$; *bryoidin*, $2(C_{10}H_{16}) + 3H_2O$; *elemic acid*, and bitter extractive.

Medical Properties and Uses. Elemi has properties analogous to those of the turpentines, but is exclusively applied to external use. In the United States it is rarely employed even in this way. In the pharmacy of Europe it enters into the composition of numerous plasters and ointments. We are told that it is occasionally brought to this country in small fragments mixed with the coarser kinds of gum arabic from the Levant and India. *Unguentum Elemi*, Br. Ph. 1885, was of the strength of about 20 per cent.

EMBELIA RIBES. Burm. f. (Nat. ord. Myrsinaceæ.) The small peppercorn-like, very aromatic fruit of this East India plant is said by Harris to be a powerful tænicide. From one to four drachms (3·88–15·5 Gm.) of the powder is given in milk, early in the morning. C. H. Warden has isolated from it *embelic* acid. (*Lancet*, July, 1887; *P. J. Tr.*, Jan. 1888.)

EMERY. *Lapis Smiridis, s. Smiris. Emeri, Corindon granuleux ferrifère, Fr. Smirgel, Schmirgel*, G. A very hard mineral, the powder of which is capable of wearing down all other substances except the diamond. It was formerly derived almost solely from the island of Naxos, in the Grecian Archipelago. According to Landerer, it has been found in Asia Minor and the Morea, and it occurs in Chester, Hampden County, Mass. (See J. Lawrence Smith, *Amer. Journ. Sci. and Arts*, 1866, xlii.) Emery is pulverized by grinding it in a steel mill, and the powder is kept in the shops of different degrees of fineness. It is used for polishing metals and hard stones. Compact corundum is now ground extensively for the manufacture of emery-wheels, etc. The corundum is found abundantly in Northern Georgia, in North Carolina, and in Chester Co., Pa. The production of emery in the United States amounted in 1896 to 1550 tons, valued at $108,500, and in 1897 to 1500 tons, valued at $105,000. The value of the imported emery in these years amounted to $148,158 and $129,882 respectively. Emery is being steadily replaced in use by the new product of the electric furnace, *carborundum*.

EMODIN. This compound, now recognized as *trioxymethylanthraquinone*, $C_{14}H_4(CH_3)(OH)_3O_2$ (see *Rheum*, 1160), as prepared from aloes, forms orange-red needles, melting at 216° C. It may be prepared from barbaloïn by extraction with ether, in which the emodin is soluble, while the aloïn is left undissolved. This ethereal extract turns red on the addition of ammonia (Borntraeger's reaction for oxymethylanthraquinones).

According to Professor Tschirch, aloe-emodin is a certain, moderate purge in man, in doses of one and three-tenths grains (0·08 Gm.), frangula emodin having about the same purgative strength. In view of the fact that in Barbadoes aloes there is only 2 per cent. of aloe-emodin, that in rhubarb there is only 2 per cent. of rhubarb-emodin with 4 or 5 per cent. of chrysophanic acid, and that in senna the percentage of emodin is much less than these figures, the belief of Prof. Tschirch that emodin is the active principle of these drugs seems highly improbable. It constitutes only a fraction of aloïn, but has to be given in four or five times the dose of aloïn to have purgative effect. In Prof. Tschirch's estimation, the superior activity of crude drugs is due to the presence in them of educts produced by oxidation or hydrolysis from the oxymethylanthraquinone. The experiments of Dr. Asher, upon which Tschirch bases his belief that in the emodin group the purgation is caused by local stimulation of the nerve-endings in the intestinal mucous membranes and reflexly excited peristalsis, were certainly not sufficient in number or thoroughness to establish the correctness of the theory.

EOSIN. $C_{20}H_8Br_4O_5$. A dye obtained by the action of phthalic anhydride upon phenols. When phthalic anhydride acts upon resorcin, $C_6H_4(OH)_2$, in the presence of a dehydrating agent like sulphuric acid or stannic chloride, at a temperature of 120° C., there is formed a compound *Resorcinphthalein*, $C_{20}H_{12}O_5$, better known as *Fluorescein*. By the action of bromine upon this is formed *tetrabrom-fluorescein* or *Eosin*, $C_{20}H_8Br_4O_5$. Soluble eosin is the potassium salt of this compound, $C_{20}H_6Br_4O_5K_2$. It forms a bronze-colored crystalline powder having a strong green reflection. Its solution in water is a red liquid having a fine green fluorescence. On the addition of hydrochloric acid the fluorescence is destroyed, the liquid becoming yellow. Eosin is largely used at present as a dye: to make a brilliant red ink, dissolve 5 grains of eosin and 10 grains of gum arabic in a fluidounce of water.

EPHEDRA VULGARIS. (L.) Prof. Nagai has extracted from this Japanese gentianaceous plant an alkaloid, *ephedrine*, which, according to M. Kinnossuke, produces in the lower animals acceleration of the pulse, with lowering of the blood-pressure, elevation of the rectal temperature, dilatation of the pupils, convulsions, and death by arrest of the heart and respiration. (*Berlin. Klin. Wochensch.*, No. 38, 1887.) Scriba found that a 10 per cent. solution dilates the pupil with certainty, in from forty to sixty minutes, without irritation; the dilatation not being complete, and the accommodation not at all or only slightly affected; and the pupils returning to normal in from five to twenty hours. An alkaloid has also been discovered in the *Ephedra monostachya*, Linné (now *E. distachya*, L.), a shrub whose branches and root are used in Siberia as a powerful remedy in *gout* and *syphilis*. According to Kobert, this alkaloid is essentially different from *ephedrine*, in not being mydriatic or poisonous. P. Spehr (*A. J. P.*, 1892, 234) considers that *E. vulgaris* contains two alkaloids, *ephedrine* and *pseudo-ephedrine*, isomeric and of the formula $C_{10}H_{15}NO$, while *E. monostachya* contains a distinct alkaloid having the formula $C_{13}H_{19}NO$. This latter, as stated by Kobert, is not mydriatic or poisonous. According to Günsberg, pseudo-ephedrine is a powerful mydriatic, its 10 per cent. solution causing in fifteen minutes dilatation of the eye through excitement of the sympathetic.

Ephedra antisyphilitica, S. Wats. (now *E. nevadensis*, S. Wats), which grows abundantly in the Nevada mountains at a height of from 4000 to 6000 feet, is much used in Arizona as a remedy in *gonorrhœa*. Prof. Loew thinks that its virtues reside in a peculiar tannin. Dose, of fluid extract, from one to two fluidrachms (3·69–7·39 C.c.).

EPIDERMIN. A surgical dressing made by fusing 15 Gm. of white wax, and triturating in a warm mortar with 15 Gm. of powdered acacia until uniform, and adding a boiling mixture of 15 Gm. each of water and glycerin, and stirring until cold. Valentine and Schwarz have given the name epidermin to an ointment vehicle said to be composed of fluorxylol and difluordiphenyl.

EPIGÆA REPENS. L. *Trailing Arbutus. Ground Laurel. May-flower. Gravel-plant.* This is a small trailing ericaceous plant, with woody stems from six to eighteen inches long, entire, cordate-ovate leaves, and small, very fragrant flowers, which appear early in the spring. It is found in the woods, and affects the sides of hills with a northern exposure. Dr. Darlington states that the plant has been supposed to be injurious to cattle, when eaten by them. (*Flora Cestrica*, 259.) Mr. Jefferson Oxley has found in this plant *arbutin*, $C_{12}H_{16}O_7$, *ursone*, $C_{20}H_{32}O_2$, *ericolin*, $C_{34}H_{56}O_{21}$ (the same constituents as are in uva ursi), tannic and formic acids, and a principle allied to gallic acid. (*A. J. P.*, xliv. 253.) Thal gives the simpler formula $C_{26}H_{30}O_3$ to ericolin. Dr. Eli Ives, of New Haven, Connecticut, in 1849, highly commended epigæa as a substitute for uva ursi, and we now know that the two drugs contain the same active principles. The decoction of the leaves and stem may be used freely.

EPILOBIUM ANGUSTIFOLIUM. L. (Now *Chamænerion angustifolium* (L.). Scop.) *Willow-herb. Herbe de St. Antoine*, Fr. *Weidenroschen, Antonskraut*, G. (Nat. ord. Onagraceæ.) There are several indigenous species of Epilobium, which have the common name of willow-herb from the resemblance of their leaves to the willow, and probably have nearly identical properties. The *E. angustifolium*, L., is the largest of them. Its leaves and roots are said to be demulcent, tonic, and astringent, and yield their virtues to water and alcohol. They are used by the "electics," generally and locally, in decoction, infusion, or cataplasm, as astringents. Oliver reports (*Brit. Med. Journ.*, ii. 1897) violent poisoning with epileptiform convulsions caused by the berries of *E. hirsutum*.

EQUISETUM HYEMALE. L. *Horsetail. Scouring Rush. Prêle*, Fr. *Schachtelhalm*, G. An indigenous equisetaceous plant, with slender annual stems from a foot and a half to three feet high, growing abundantly in the Northern States, and preferring wet places, as the banks of streams, etc. The plant derives its name of scouring rush from its use in scouring, for which it is fitted by the silicious character of the stems. Examined by F. J. Young (*A. J. P.*, 1886, 419), it yielded to petroleum benzin as a solvent 1·4 per cent. of a brownish-green, semi-liquid, fixed oil, which was readily saponified. It also contained a green semi-solid resin, sugar, and mucilage. The infusion of the whole plant has the reputation of being diuretic, and is used sometimes in *dropsical* and *renal diseases*.

ERECHTHITES HIERACIFOLIA. (L.) Raf. *Fireweed.* An annual indigenous composite plant, growing in moist woods and recent clearings, and having a rank somewhat aromatic odor. Its taste is bitterish, slightly acrid, and disagreeable. It yields to water. It has been especially recommended in *dysentery*. It is apt to infest the peppermint fields of Michigan; and its oil is said sometimes to deteriorate the oil of peppermint from that region. It has been shown, however, that *Erigeron Canadense* is far more injurious.

ERGOTINOL. *Liquor Ammonii Ergotinatis*, a preparation of ergot made by Vosswinkel, sixteen minims (1 C.c.) corresponding to eight grains (0.5 Gm.) of extract of ergot. The dose for subcutaneous injection is sixteen minims (1 C.c.). It is recommended in excessive *menorrhagia*.

ERIGERON. *Fleabane. Scabious. Sweet Scabious. Daisy Fleabane. Herbe d'érigeron, Herbe de Vergerette*, Fr. *Berufkraut*, G. Under this name the U. S. Pharmacopœia of 1870 recognized the herbal portions of *E. heterophyllus*, Muhl (now *E. annuus* (L.) Pers.), and *E. Philadelphicus*, L. (Nat. ord. Compositæ.)

E. heterophyllus, Muhl., is a biennial herbaceous plant, belonging both to North America and to Europe. It has a branching root, with several erect, roundish, striated, pubescent stems, much divided near the top, and two or three feet high. The lower leaves are ovate, acute, deeply toothed, with long winged footstalks; the upper are lanceolate, acute, deeply serrate in the middle, and sessile; the floral leaves are lanceolate and entire; all, except the radical, are ciliate at the base. The flowers are in terminal corymbs. The florets of the disk are yellow; those of the ray numerous, very slender, and of a white, pale blue, or pale purple color. The flowering period is from June to October.

E. strigosum, Muhl. (now *E. ramosus* (Walt.), B. S. P.), grows with *E. annuus*, and is frequently collected with it. It is distinguished by its leaves being nearly entire, and by both stems and leaves

being almost smooth or furnished only with minute appressed hairs.

Erigeron Philadelphicus. L. *Philadelphia fleabane* is perennial and herbaceous, with a branching yellowish root, and from one to five erect stems, which rise two or three feet in height, and are much branched at top. The whole plant is pubescent. The lower leaves are ovate-lanceolate, nearly obtuse, ciliate on the margin, entire or marked with a few serratures, and supported on very long footstalks; the upper are narrow, oblong, somewhat wedge-shaped, obtuse, entire, sessile, and slightly embrace the stem; the floral leaves are small and lanceolate. The flowers are numerous, radiate, and disposed in a panicled corymb, with long peduncles bearing from one to three flowers. They resemble those of the preceding species in color, and make their appearance about the same period.

The three species are abundant in the middle portions of the United States, grow in open fields, and are probably of identical medical value. They are popularly known as *scabious*. The whole herb is used, and should be collected while the plants are in flower. It has a feebly aromatic odor and bitterish taste, and imparts its properties to boiling water. Mr. F. L. John, of Philadelphia, obtained from *E. Philadelphicus* a volatile oil by distillation, but in exceedingly small proportion, forty-five pounds of the herb having yielded only half a drachm of the oil. As described by Prof. Procter, this is of a greenish-yellow color, a powerful penetrating, aromatic odor, and a bitterish, pungent, disagreeable taste. It is more viscid than the oil of *E. Canadense*, L., has a higher sp. gr. (0·946), and contains more oxygen. (*A. J. P.*, xxvii. 105.) Fleabane is diuretic and stomachic, and has been used in *gravel* and in *dropsy;* infusion (℥i to Oi), one pint in twenty-four hours.

The U. S. Pharmacopœia also formerly recognized *Erigeron Canadense.* L. (now *Leptilon Canadense* (L.), Britt.). *Horseweed. Mare's tail. Fireweed. Butter-weed. Colt's-tail. Canada fleabane* is an indigenous annual plant, with a stem from two to six feet high, covered with stiff hairs, and divided into many branches. The leaves are linear-lanceolate, and edged with hairs; those at the root are dentate. The flowers are very small, numerous, white, and arranged in terminal panicles. They differ from those of the other species of Erigeron in having an oblong calyx, the rays very minute and more numerous than the florets of the disk, and the seed-down simple. Hence by some botanists the plant is placed in a sub-genus with the title *Cænotus*, Raf. Another variety of *E. Canadense*, which Mr. Nuttall makes a distinct species, with the title *E. pusillus*, is not more than from four to six inches high, and has an erect smooth stem, less branched than the preceding, with all its leaves entire, and scabrous on the margin. The panicle is simple, and the peduncles filiform, nearly naked, divaricate, each bearing two or three flowers.

Canada fleabane is very common throughout the northern and middle sections of the United States, and has become naturalized in many parts of Europe. It abounds in neglected fields, and is reported to be a very troublesome weed on the peppermint plantations of the West. It blooms in July and August. The plant, all parts of which are medicinal, should be collected while in flower. The leaves and flowers are said to be the most active parts. It has an agreeable odor, and a bitterish, acrid, somewhat astringent taste. Among its constituents, according to De Puy, are bitter extractive, tannin, gallic acid, and volatile oil. Both alcohol and water extract its virtues. Its acrimony is diminished by decoction, in consequence, probably, of the escape of the oil, upon which its virtues in part depend. (See *Oleum Erigerontis Canadensis.*) According to De Puy, Canada fleabane is diuretic, tonic, and astringent; and useful in *dropsical complaints* and *diarrhœa.* It has been given in substance (dose, a drachm, or 3·88 Gm.), infusion, tincture, or extract (dose, ten grains, or 0·647 Gm.), but the oil is the only proper preparation. The oil is certainly of value in *uterine, pulmonary,* and other *internal hemorrhages,* in doses of from five to fifteen drops (0·25–0·75 C.c.) every two hours.

ERIOBOTRYA JAPONICA. Lindl. *Loquat.* (Nat. ord. Rosaceæ.) The seeds and leaves of this tree are said to contain amygdalin and emulsin, and to yield hydrocyanic acid in poisonous quantities. (*P. J. Tr.*, Aug. 1885.)

ERODIUM CICUTARIUM. L'Herit. *Storksbill.* An annual hairy plant, belonging to the Geraniaceæ. It is highly recommended by W. Abbotts Smith in *dropsy.* (See *Am. Journ. of Med. Sci.*, 1865.)

ERYNGIUM AQUATICUM. L. *Button Snakeroot. Corn Snakeroot. Rattlesnake's Master.* The *button snakeroot* or *water eryngo* is an indigenous umbelliferous plant, with a perennial tuberous root, and a stem two or three feet high (sometimes, according to Pursh, six feet), generally branching by forks, but trichotomous above. The leaves are very long, linear-lanceolate on the upper part of the stem, sword-shaped below, with bristly spines at distant intervals upon their margin. The floral leaves are lanceolate and dentate. The flowers are white or pale, and in globose heads, with the leaflets of the involucrum shorter than the head, and, like the scales of the receptacle, entire. This plant is found in low wet places, as far south as Florida and Texas. The root, which is the medicinal portion, has a bitter, pungent aromatic taste, provoking, when chewed, a flow of saliva. It is said to be diaphoretic, expectorant, in large doses emetic, and has been used as a substitute for senega. (Bigelow.)

ERYTHRINA BROTEROI. An Australian tree of the nat. ord. Leguminosæ, the bark of which yields an alkaloid, *erythrinine*, which is asserted to be identical with the alkaloid *erythrine* obtained from *E. corallodendron*, L., a Brazilian plant. The name erythrin is also applied to a dye-stuff.

ERYTHROL TETRANITRATE. $C_4H_6(NO_3)_4$. Erythrol tetranitrate is solid and crystalline, and melts at 61° C. (142° F.). When pure it is colorless, and if kept in a dark and moderately cool place is fairly stable. If exposed to warmth, and especially sunlight, it rapidly undergoes decomposition, turning yellow and giving off nitrous fumes. It is also capable of rapid decomposition, and death has been caused by the explosion following its trituration in a mortar with glucose. (*Brit. Med. Journ.*, i. 1896.) Its solubility in water is slight, but it dissolves readily in alcohol and in ether. It is a vaso-dilator, and belongs to the group of which glycerol trinitrate (glonoin) is the representative. Blood-pressure experiments show that the nitrates of erythrol and mannitol have a less marked but more prolonged action than those of glycerol and glycol. In man the effects of the

remedy are said not to be apparent in less than half an hour and to last for over an hour. It may be used in all cases for which glonoin is employed, and has been especially commended in *angina*. Its alcoholic solution is explosive, so that it should always be used in tablets, in whose preparation great care is necessary. Dose, from a half to one grain (0·03–0·064 Gm.).

ERYTHRONIUM AMERICANUM. Ker. (*E. lanceolatum*, Pursh.) This is an indigenous, perennial, liliaceous plant, sometimes called, after the European species, *dog's-tooth violet*. The bulb (corm), which is brown externally, white and solid within, sends up a single naked slender flower-stem, and two smooth, lanceolate, nearly equal leaves, sheathing at their base, with an obtuse, callous point, and of a brownish-green color diversified by numerous irregular spots. The flower is solitary, nodding, yellow, with oblong-lanceolate petals obtuse at the point, a club-shaped undivided style, and a three-lobed stigma. The Erythronium grows in woods and other shady places from Nova Scotia to Florida and west to Minnesota and Arkansas. It flowers in the latter part of April or early in May. All parts of it are active. In the dose of twenty or thirty grains (1·29 or 1·94 Gm.) the recent bulb is emetic. The leaves are said to be more powerful. The activity of the plant is diminished by drying.

ESCHSCHOLZIA CALIFORNICA. *Chamisso.* Attention has been brought to this Californian member of the Papaveraceæ, as a powerful soporific and analgesic, which is free from the disadvantages of opium. It was analyzed many years ago by Prof. G. F. Walz, who found in it *sanguinarine* and two new alkaloids. It is stated also that in 1862 Walz found succinic acid in it. Bardet and Adrian (*Gaz. Hebdom. Méd. et Chir.*, Nov. 1888) assert that they have obtained a glucoside, an alkaloid, and morphine in the proportion of from five to six grains in two pounds of the dried product. The narcotic power of the drug seems to be very weak, since, according to Bardet, three drachms were necessary to kill a rabbit. Ter-Zakariant (*Gaz. Méd. de Paris*, Feb. 1889) states that the alcoholic extract acts as a respiratory depressant and narcotic, affecting in toxic dose also the spinal cord. Dujardin-Beaumetz has used the extract in commencing doses of twelve and three-tenths grains (0·8 Gm.), increasing to one hundred and eighty-five grains (12 Gm.) a day, and affirms that it is a harmless soporific and analgesic.

ETHOXYCAFFEINE ($C_{10}H_{14}N_4O_3$) is prepared by boiling 3 parts of bromocaffeine with 2 parts of potassium hydrate and 10 parts of alcohol. It forms crystals fusing at 140° C; is difficultly soluble in water and ether, easily soluble in hot alcohol, insoluble in alkalies, soluble without decomposition in cold dilute hydrochloric acid; on warming it is decomposed. Filehne (*Archiv für Anat. und Phys.*, 1886) finds that ethoxycaffeine has upon frogs and rabbits a narcotic effect. From seven to ten grains of it produced in man vertigo, intellectual torpor, and sometimes pain in the head. Dujardin-Beaumetz (*Bull de Thérap.*, March, 1886) finds that it acts in the guinea-pig as a narcotic and diuretic, and has given it for *headache* in doses of from three to fifteen grains (0·194–0·971 Gm.) a day, in capsules or dissolved in water by means of sodium salicylate. Cases of painful *zona*, *migraine*, and *nervous headaches* were relieved. The larger doses produced gastric irritation.

ETHYL BROMIDE. *Bromide of Ethyl. Hydrobromic Ether. Bromic Ether. Æther Bromatis. Bromure d'éthyle, Ether hydrobromique*, Fr. *Bromäthyl, Bromwasserstoffäther*, G. C_2H_5Br. This ether was discovered by Sérullas in 1827, who prepared it by acting on alcohol with bromine in the presence of phosphorus. (*Ann. Ch. Phys.*, xxxiv. 99.) Personne suggested the use of amorphous phosphorus, as less dangerous than ordinary phosphorus, and more convenient to manipulate. (*Compt.-Rend.*, iii. 468.) A process was also recommended by Prof. Remington, based upon Personne's suggestion. (*Proc. A. P. A.*, 1877.) De Vrij proposed to decompose potassium bromide with sulphuric acid in the presence of alcohol, and a modification of his method is now generally employed. We have obtained good results from the following.

Take of potassium bromide (not powdered) 58 parts; sulphuric acid, sp. gr. 1·838, 44 parts; alcohol (clean), 95 per cent., 44 parts; water, 28 parts. Pour the water into a flask having double the capacity of the liquid ingredients above, and gradually add the acid; when the liquid has become cool, add the potassium bromide, and having placed the flask in a sand-bath, adjust a thermometer, and with a bent glass tube connect the flask with a well-cooled condenser; insert a narrow glass tube in the cork of the flask, and by means of a short rubber tube connect it with a narrow glass tube which is terminated by a siphon; the shorter limb of this siphon is inserted in the bottle containing the alcohol, which is elevated three feet or more above the flask. Heat the contents of the flask to 116° C. (240 8° F.), and having attached a screw pinch-cock to the short rubber tube of the siphon, allow the alcohol to drop or flow in a small stream into the flask, carefully regulating the rate or flow so that the temperature shall not fall below 100° C. (212° F.), nor rise above 116° C. (240 8° F.). When all the alcohol has passed into the flask, continue the distillation until the temperature rises to 116° C. (240·8° F.), and then disconnect the receiving flask. Agitate the distillate with an equal bulk of distilled water, to which has been added five parts of solution of soda (or sufficient to render the liquid slightly alkaline), and when the mixture has clearly separated into two layers, pour off the uppermost layer, and, having introduced the heavier liquid into a clean flask containing a few fragments of calcium chloride, redistil it. For other methods of manufacture, see *N. R.*, 1877, 200; 1879, 8; *A. J. P.*, 1879, 292; 1880, 248, 280, 298; also *Pharm. Centralh.*, xxviii., 1887, 122. For Dr. L. Wolff's process for making it economically, see *A. J. P.*, 1880.

Ethyl bromide is a colorless, very volatile liquid, not inflammable, having an agreeable odor, and a hot, saccharine taste. Its sp. gr. is 1·450. It boils at from 38°–39° C. (100·4°–102° F.). It is very sparingly soluble in water, freely soluble in strong alcohol and ether. When a small portion is evaporated from a porcelain plate by causing it to flow to and fro over the surface, little or no foreign odor is yielded as the last portions pass off, and the plate is covered with a slight deposit of moisture.

The ethyl bromide prepared from alcohol and bromine in the presence of amorphous phosphorus should not be used in medicine because of the possible presence of organic compounds of sulphur and arsenic. Shaken with distilled water, the latter should not show any acid reaction from hydrobromic

acid, nor should it cause any appreciable turbidity with silver nitrate. Shaken with an equal volume of pure concentrated sulphuric acid, no color should develop even after an hour's time; otherwise ethylene bromide may be present. Dropped slowly into potassium iodide solution, the drops of the ethyl bromide should settle to the bottom of the vessel without developing any appearance of violet color, which would indicate free bromine. Ethyl bromide should be kept in amber-colored glass bottles, completely filled and well stoppered. (Fischer, *Die Neuere Arzneimittel*, 6te Aufl., 74.)

Some years ago ethyl bromide was proposed and largely used as an anæsthetic. In a series of experiments made with it at that time, Dr. H. C. Wood found that its action upon the heart is the same as that of chloroform, and that injected into the jugular vein it causes cardiac arrest. The occurrence of two deaths from it, one of them distinctly syncopal, partly arrested its successful career, although it certainly acts very promptly and agreeably, and its influence passes off with extraordinary rapidity. Recently, professional attention has been strongly redirected to the bromide, and it is asserted that the evil effects produced in its early use were due to the presence of impurities, especially of ethylene bromide. Hamecker (*Internat. Klin.*, Dec. 20, 1891) affirms that in experiments upon the lower animals, made with pure ethyl bromide, death always occurred through arrest of the respiration, the heart continuing to beat from fifteen to nineteen minutes after cessation of the breathing.

In accordance with this, Dr. Gilles asserted in 1892 that in twenty thousand successive administrations with the ethyl bromide in Germany there had been no fatal results when a chemically pure bromide had been used. Since this assertion a number of deaths (five or six) have been reported, in which it has been distinctly proved that a pure ethyl bromide was given. Gurlt (*Arch. f. Klin. Chir.*, lv.) puts the mortality-rate at 1 in 5896 inhalations, and the studies of Wood and Cerna indicate that it is about as dangerous as chloroform. Moreover, it has been shown by Hennicke that the ethyl bromide undergoes decomposition with the liberation of bromine compounds from the system. We have at present no definite knowledge as to the action of these bromine compounds, but it is probable that they are capable of producing secondary changes in the organic structure, especially since cases have been reported by Reich and by Hatten of death from acute fatty degeneration after ethyl bromization. It has been largely used as a practical anæsthetic. (*S. J.*, Bd. cclvii. 234; Bd. cclx. 18.) The narcosis is said to be produced almost abruptly, with practically no stage of preliminary excitation, and to be accompanied by little tendency to muscular relaxation. Its effects pass off so suddenly as to endanger their continuance during the operation. On account of its loss by evaporation it is a very expensive anæsthetic. Ethyl bromide has been especially recommended for use in *parturition*, it being stated that it suspends the pain of the uterine contractions without influencing their force, and has been employed to a considerable extent in cases when a brief anæsthetic is required. In using it, from two to four drachms may be put upon an Allis inhaler or upon a napkin.

ETHYL CHLORIDE. *Chlorethyl.* This ether was discovered by Rouelle, but first obtained in sufficient quantities to permit the examination of its properties by Basse. It may be procured by several processes, but the following is the best. Distil a mixture of equal measures of concentrated hydrochloric acid and alcohol, and receive the product, by means of a curved glass tube, in a tubulated bottle, half filled with water at a temperature between 21·1° C. (70° F.) and 26·6° C. (80° F.), and connected by means of a second tube with another bottle, loosely corked, and surrounded by a mixture of common salt with snow or pounded ice. The ether, as it enters the first bottle, is mixed with alcohol and acid, which are retained by the water; while the pure ether passes forward, and is condensed in the refrigerated bottle. It must be kept in strong bottles, well secured with ground stoppers covered with leather. Before being opened, the bottle should be cooled to the freezing point.

Ethyl chloride is a colorless liquid, having a strong, slightly saccharine, alliaceous taste, and a penetrating, ethereal, alliaceous smell. Its sp. gr. at the temperature of 0° C. (32° F.) is 0·9214. It is extremely volatile, entering into ebullition at 10° C. (50° F.), so that in summer it may be collected in the gaseous state, in bell-glasses over water. Its sp. gr. in the state of vapor is 2·22. When kindled as issuing from a fine orifice, it burns with an emerald-green flame, without smoke, diffusing a strong odor of hydrochloric acid; but, when set on fire in quantities, it burns with a greenish-yellow, smoky flame. Water dissolves one-fiftieth of its weight of this ether, and acquires a sweetish, ethereal taste; and alcohol unites with it in all proportions. These solutions are not precipitated by silver nitrate, showing that the chlorine present is in a peculiar state of combination. Like common ether and ethyl nitrite, it dissolves sulphur and phosphorus, the fixed and volatile oils, and many other substances. It consists of one atom of chlorine combined with the monatomic radical or group C_2H_5, *ethyl*, and its composition is sufficiently shown by the reaction for its production:

$$C_2H_5,OH + HCl = C_2H_5,Cl + H_2O.$$

Owing to its extreme volatility, it cannot be kept readily. It may, however, be preserved in a cool cellar, the temperature of which does not rise above 7·2° C. (45° F.) or 10° C. (50° F.), being well secured in bottles, which should be placed reversed. Advantage has been taken of the great volatility of ethyl chloride for practical use as a local anæsthetic by freezing. It is now furnished for dental and other use, in hermetically sealed tubes, so made that when the end is broken off, and the tube held in the hand, the liquid comes out in a fine stream which may be directed upon the gum to be frozen. Drs. H. C. Wood and David Cerna (*Dental Cosmos*, 1892) find that ethyl chloride taken into the blood acts very much like chloroform. On account of its great inflammability it should not be used near a light or flame. *Alcoholic muriatic ether*, or a solution of ethyl chloride in an equal bulk of alcohol, has been used as an internal stimulant. Dose, from ten to thirty drops.

ETHYL FLUORIDE. *Fluoride of Ethyl*, C_2H_5F, is said to cause in animals violent excitement, followed quickly by death. For properties and method of preparation, see *Chem. News*, Jan. 1889, also *Bull. Acad. de Méd.*, Mars, 1890.

ETHYL FORMATE. *Formic Ether. Ethyl-formic ether.* A liquid with a peach-kernel odor, sp. gr. 0·937, soluble in ten parts of water. This

ether is reputed to be useful in the treatment of infectious diseases of the respiratory organs.

ETHYL IODIDE. *Hydriodic Ether. Iodide of Ethyl. Iodure d'éthyle, Ether hydriodique,* Fr. *Jodäthyl, Jodwasserstoffäther,* G. C_2H_5I. This ether may be obtained by gradually and cautiously mixing five parts of alcohol, ten of iodine, and one of phosphorus, and distilling. The residue of the distillation, as ascertained by D. K. Tuttle, is ethyl-phosphoric acid. The best method of proceeding, in order to avoid danger, according to Soubeiran, is to melt the phosphorus with a gentle heat under the alcohol, contained in a wide-mouthed matrass, and to add the iodine gradually through a tube, sealed at the lower end, but perforated at the same end with a number of small holes. The tube is made to pass through a grooved cork, to give exit to the vapors, and is so adjusted as to reach nearly to the surface of the melted phosphorus. The matter in the matrass is distilled to the extent of four-fifths, the distillate is washed with water to separate alcohol, and the decanted ether is dried by the addition of a few pieces of calcium chloride. Dr. de Vrij recommends the following method for procuring this ether on a large scale. Absolute alcohol is to be saturated with dry hydrochloric acid gas, the liquid being kept well cooled; and the amount of the acid is to be determined by a sample. The liquid thus saturated is to be put into a retort, with as much potassium iodide as may be necessary to form potassium chloride; the mixture is to stand for a day, and is then to be submitted to distillation. Finally, the ether which comes over is to be washed and rectified. (See *A. J. P.*, 1859, 170.) Personne (*Comptes-Rendus*, 51, 468) proposed to use amorphous phosphorus instead of the ordinary kind, thus avoiding danger. Reith and Beilstein (*Ann. Chem. Pharm.*, 126, 250) propose the following process. Mix 10 parts amorphous phosphorus with 50 parts alcohol of sp. gr. 0·83; add 100 parts dry iodine in small portions. The mixture should be allowed to stand twenty-four hours before distillation, and the distillation decolorized by a solution of soda, and deprived of water by redistilling in contact with calcium chloride. Hydriodic ether is a colorless non-inflammable liquid, insoluble in water, with a penetrating ethereal odor and pungent taste. Its density is 1·92, and boiling point from 71°–72° C. (160°–161·6° F.). Exposed to the air it becomes red from the liberation of iodine; the change in color is prevented by adding to the bottle containing it a globule of mercury. M. Huette has proposed this ether, placed under a layer of water, as a medicine, to be used by inhalation. Fifteen or twenty inspirations suffice to impregnate the system with iodine. It acts as a powerful anæsthetic, when sufficiently long inhaled. It is said to increase the appetite, render the pulse fuller, and give vivacity to the feelings and activity to the intellect. (See *A. J. P.*, xxiii. 156.) Mr. James Turnbull, of Liverpool, and Dr. Henry Fisher, of New York, have used this ether by inhalation with satisfactory results in *chronic bronchitis* and *phthisis*. The dose is fifteen drops, three or four times a day, inhaled from a handkerchief. Hydriodic ether often has an unpleasant smell from the presence of foreign substances, which renders it offensive to patients. Phosphorus is a common and injurious impurity.

According to Linosier and Lannois (*Semaine Méd.*, 1897), ethyl iodide affords an excellent method of affecting the general system by external application. Absorption of the iodine is rapid; the liquid should be applied with a brush and then covered with paraffined paper: after applying two fluidrachms they recovered thirteen grains of iodine from the urine.

ETHYLENE BROMIDE. *Brom-ethylene. Æthylenum Bromatum.* $C_2H_4Br_2$. This is a colorless oily liquid smelling like chloroform, with a sweet burning taste. It boils at 131·6° C., and solidifies at 0° C. to a crystalline mass; sp. gr. at 20° C. 2·178. It is insoluble in water, miscible with alcohol in all proportions. The chief medical importance of this agent grows out of its liability to be confounded with the ethyl bromide. One death has in this way been produced. Ten drachms of it were inhaled without the production of anæsthesia, followed by uncontrollable vomiting and complete suppression of urine. On account of its containing over 85 per cent. of bromine, Prof. Donath has used it in *epilepsy*. He gives it in an emulsion with oil, or mixed with almond oil in capsules. Children from eight to ten years begin with from ten to twenty drops of a 5 per cent. solution; the adult dose is six drops of ethylene bromide, three times a day. (See also *P. J. Tr.*, xxi. 1068.)

EUCAINE. *Eucaine Hydrochlorate. Alpha-Eucaine, Beta-Eucaine.* Under the name of Eucaine Hydrochlorate, manufacturers have introduced into practical medicine two distinctly different substances, distinguishing them as Eucaine Hydrochlorate A, or *Alpha-Eucaine*, and Eucaine Hydrochlorate B, or *Beta-Eucaine*, producing much confusion in clinical reports, as it is often impossible to be certain which substance the writer of the article has worked with. The difficulty has been increased by the extraordinary "puffing" of the article for commercial purposes.

Eucaine Hydrochlorate A, or *Alpha-Eucaine*, was first described, and should have had the name of Eucaine confined to it. It is *n-methyl-benzoyltetramethyl-y-oxypiperidincarboxylicmethylester*. Eucaine Hydrochlorate B, or *Beta-Eucaine*, is *benzoylvinyldiacetonalkamine*. The first of these has the formula $C_{19}H_{27}NO_4.HCl + H_2O$, and is a derivative of triacetonamine. This triacetonamine is changed by treatment with hydrocyanic acid, followed by boiling with water, into oxymethyl piperidincarbonic acid, and this by the introduction of the benzoyl and methyl groups into the base eucaine, which is then crystallized out as the hydrochlorate. Eucaine B, on the other hand, is the benzoyl derivative of *vinyl-diaceton alkalamine*. It is asserted to be free from irritating properties and less toxic than Eucaine A. Its formula is $C_{15}H_{21}NO_2.HCl$.

As the manufacturers themselves, when the name Eucaine Hydrochlorate is used, supply Alpha-Eucaine, and as it was the first brought forward, we shall consider it in this article as the proper *Eucaine Hydrochlorate*, $C_{19}H_{27}NO_4.HCl + H_2O$. It is a white, neutral, crystalline powder, soluble in ten parts of cold water,—*i.e.*, about 9 per cent.

Physiological Action. The physiological action of eucaine has not been sufficiently studied to allow certainty of knowledge. According to Ver Eecke, it produces in the frog violent convulsions, followed by paralysis of peripheral origin; and in the warm-blooded animals convulsions resulting in death from asphyxia. It is affirmed by the observer mentioned to lower the blood-pressure by

diminishing peripheral resistance, although acting at the same time on the heart directly both upon the intra-cardiac ganglia and the muscle structure. It is said also to increase diuresis, with, after toxic doses, glycosuria. (*Bull. Roy. Acad. Méd.*, Belgium, 1897.)

In practical medicine the only value of eucaine hydrochlorate is as a local anæsthetic. There can be no doubt but that it is endowed with distinct local anæsthetic powers, but its superiority over cocaine seems to be more than doubtful. It has been affirmed that it is free from toxic properties. This is incorrect, but it is less toxic than cocaine. The disagreeable symptoms which have occasionally followed its use are very similar to those seen after cocaine. It is more irritant than cocaine, so that when dropped into the eye it produces much smarting. The anæsthesia is said to be complete in five minutes after application to the eye, and to last not over twenty-five minutes; in relative strength eucaine is stated to be to cocaine as seven is to ten. Its influence upon the blood-vessels is entirely different from that of cocaine, it causing dilatation rather than contraction, so that it fails in rhinoscopic surgery to lessen the turbinated bodies, and is not hæmostatic.

In the Jefferson College Surgical Clinic it has been very largely tested as a surgical anæsthetic. In no case have any toxic symptoms been produced, and the anæsthetic action of the eucaine has been very satisfactory; but in a number of cases a peculiar slow, persistent sloughing has followed its use, especially when, as in the removal of an ingrowing nail, fatty tissues, bursa, or tendon sheaths are concerned in the operation. Its employment in diseases of the bladder has not unusually been followed by pronounced inflammation. (J. Chalmers Da Costa.) In minor surgery a 5 per cent. solution is to be used; for dental purposes 4 to 9 per cent.; for diseases of the nose, throat, and ear 2 to 8 per cent.; for infiltration anæsthesia $\frac{1}{10}$ to 1 per cent.

Eucaine Hydrochlorate B ($C_{15}H_{21}NO_2.HCl$) is a white, neutral, crystalline powder, soluble in from 27 to 28 parts of cold water,—*i.e.*, to the amount of from 3 to 4 per cent. at the ordinary temperature of the room. To make more concentrated solutions it must be slightly warmed. Such concentrated solutions remain perfectly clear quite long enough for the completion of an operation. If precipitation occurs after prolonged standing, the solution may be clarified by moderately warming it. It is much less irritant than either Eucaine A or cocaine; its anæsthetic action appears to be equally powerful with, and its toxic action is only half as strong as, that of Eucaine A. It has been especially used in ophthalmic practice.

EUCALYPTUS MANNA. *Australian Manna.* This substance exudes during the summer months from punctures made in the bark and leaves of the Australian trees *Eucalyptus mannifera*, A. Cunn (*E. viminalis*, Labill). It occurs in small rounded opaque masses, and is said medically to resemble ordinary manna.

EUCASIN is a casein ammonia compound which is obtained by passing ammonia gas over casein. It is a grayish-white powder, having an odor somewhat like buttermilk, readily soluble in hot water. It has been brought forward by Salkowski as a very easily digested food. It may be given in broths, or with cocoa; and, according to Feustell (*Deutsche Medicin. Wochensch.*, xxii. 1896), is a valuable food in cases of great failure of digestion. From thirty to forty grains of eucasin correspond to twenty-four to thirty-two grains of albumen.

EUDERMOL. *Nicotine Salicylate.* A colorless, odorless crystalline salt soluble in water, containing 54 per cent. of nicotine. It is used externally in skin diseases in the form of an ointment.

EUGALLOL. *Pyrogallol-mono-acetate.* A thick transparent mass, brownish yellow in color, soluble in water and in its own weight of acetone. A 33 per cent. acetone solution is used externally as a substitute for pyrogallol in the treatment of psoriasis.

EUGENIA CHEQUEN. Molina. *Myrtus Cheken.* Spreng. *Cheken. Chekan. Chequen.* The leaves of this myrtaceous evergreen shrub, indigenous to Chili, are used in their native country as a remedy in *chronic respiratory catarrh*, and have been strongly recommended by Dr. Murrell and others in *chronic bronchitis*. Their virtues appear to reside in the tannin, and especially in the volatile oil that they contain. Fritz Wein (*Arch. de Pharm.*, 1888, 665) examined cheken leaves proximately; he found a volatile oil and three crystalline bodies, *chekenon*, *chekenin*, and *chekenetin*, and an amorphous bitter principle. The volatile oil is probably the proper preparation for use. The dose of the fluid extract is from one to three fluidrachms (3·7–11 C.c.).

EUGENIA JAMBOLANA. Lam. *Jambul. Jamboo. Java Plum.* This is a large tree belonging to the Myrtaceæ, growing in East India and also in Queensland; well known on account of its popular edible fruit. Jambul bark is a dense, hard bark, of a pinkish-brown or reddish-brown color, with a whitish-gray mottled epidermis adherent to portions of its outer surface; the inner surface is of a somewhat silky lustre, frequently coarsely marked by waving lines or ridges; the fresh fracture varies from pinkish or purplish to fawn color, sometimes distinctly but shortly fibrous, more commonly absolutely abrupt; the thickness of the bark varies from a quarter to nearly one inch. The taste is somewhat bitter, astringent, after a time distinctly pungent. The seeds are grayish black or blackish gray, having a shape resembling that of the cut-off ends of a cylinder, being abruptly truncated at the base, above rounded or dome-shaped. They are about a third of an inch in diameter and three-eighths of an inch long; so hard and dense that they cannot be chewed, and are almost tasteless. The analysis of the seeds by Mr. Thomas Christy yields the following results. Essential oil, a trace; chlorophyll and fat, 0·37; resin soluble in alcohol and ether, 0·30; gallic acid, 1·65; albumen, 1·25; colored extractive soluble in water, 2·70; moisture, 10·00; insoluble resin, 83·73.

In the experiments made by Mr. Thomas Christy, of London (*P. J. Tr.*, 1888), it was found that when sufficient diastatic matter was mixed with fifty grains of starch to convert 45 per cent. of the latter in fifty minutes into sugar, the addition of twenty-five grains of powdered jambul seeds reduced the conversion of the starch to 12 per cent. We have no knowledge of the effect of jambul or its active properties upon the general organization, but Prof. Binz (*Verhandl. der Kongr. für Innere Med.*, Wiesbaden, 1886) found that when dogs were made diabetic by the administration of phlorizin, according to the method of Von Mering, the exhibition of jambul reduced the excretion of sugar from

50 to 90 per cent. without the production of any evidences of poisoning by the jambul. In India, jambul has long been used as a stomachic astringent and carminative in *diarrhœa*, and also in the treatment of *diabetes*. The first therapeutic trials in Europe appear to have been made by Clacius, who found that the drug notably reduced the excretion of sugar in diabetic patients. The practice has been largely followed, and there would seem to be no doubt that in occasional cases of glycosuria jambul does good. Dr. H. C. Wood has seen the sugar of the urine entirely disappear under its use. No cases of poisoning or of disagreeable results from it have been reported. The best preparation appears to be the fluid extract. The commencing dose may be ten minims (0·62 C.c.), three times a day, given in emulsion or in capsules, rapidly increased to a fluidrachm (3·69 C.c.).

EUGENOL ACETAMIDE. $C_{10}H_{11}O_2.(CO.CH_2NH_2)$. This substance occurs in shining scales or needles, soluble in alcohol and water, melting at 110° C. According to Merck, it is a local anæsthetic and at the same time antiseptic.

EUGENOL IODIDE. *Iodo-eugenol.* $C_6H_2I(C_3H_5)(OCH_3)OH$. A yellowish, inodorous, insoluble powder obtained by acting on eugenol-sodium with iodine. It is used as an antiseptic, and said to resemble aristol.

EULACHON OIL. The fish known by the Indians of the North Pacific under the name of *Eulachon* or *Oulachon*, and by the English as *Hoolakins* or *Candle fish*, the *Thaleichthys Pacificus* of scientists, yields a great abundance of an oil which has been proposed as a substitute for cod-liver oil. According to the editor of *N. R.* (1881, 356), this oil first begins to congeal and become opaque at —7° C. (19·4° F.), although authorities state that at ordinary temperatures it grows solid and lard-like. Specific gravity at 60° F. 0·907; mixed with one-half its volume of nitric acid, specific gravity 1·37, it develops a beautiful pink color which fades slowly to amber, and after standing fifteen hours it is considerably thickened and changed to a deep amber color of a reddish cast. It contains about 20 per cent. of palmitic acid and stearic acid, and 60 per cent. of oleic acid and 13 per cent. of an unsaponifiable substance, which resembles the similar constituent of sperm oil. (*Therap. Gaz.*, Sept. 15, 1884.)

EUPHORBIA. *Wild Ipecac. Wild Hippo. Euphorbe*, Fr. *Wolfsmilch*, G. The genus Euphorbia (nat. ord. Euphorbiaceæ) contains numerous species, having the common property of yielding a milky juice. They are herbaceous or shrubby, with or without leaves; and the leafless species, which are chiefly confined to the African deserts, have fleshy, naked, or spiny stems, like those of the Cactus. They nearly all afford products which act powerfully as emetics and cathartics, and in overdoses occasion dangerous if not fatal prostration, with symptoms of inflamed gastro-intestinal mucous membrane. Their milky juice, which concretes on exposure, usually possesses these properties in a high degree, and, in addition, that of powerfully irritating the skin when applied to it. The U. S. Pharmacopœia formerly recognized the indigenous species *E. corollata*, L., and *E. ipecacuanha*, L. In a full dose, the root of *E. corollata*, L., operates actively and with sufficient certainty as an emetic, producing ordinarily several discharges from the stomach, and sometimes acting with considerable energy upon the bowels. In quantities insufficient to vomit, it excites nausea, almost always followed by brisk purging. In still smaller doses it is diaphoretic and expectorant. It is, however, too harsh and uncertain in its action for practical use, and has passed entirely out of vogue. The dose of the dried root as an emetic is from ten to twenty grains (0·647–1·29 Gm.), as a cathartic from three to ten grains (0·194–0·647 Gm.). The recent root, bruised and applied to the skin, produces vesication. C. Petzolt found in the root of *E. ipecacuanha*, L., fixed oil, resin, starch, glucose, and various salts. The resinous matter was a dark mass, of a taste slight at first but after a time nauseous and pungent, readily dissolved by alcohol, but insoluble in ether and benzin, and, when swallowed, producing in half-grain doses watery stools, and in one-and-a-half or two-grain doses nausea and vomiting. It gave no evidence of the presence of an alkaloid. (*A. J. P.*, 1873, 255.) The medical properties of *E. ipecacuanha*, L., resemble those of *E. corollata*, L., though it is said to be somewhat milder. The indigenous *E. hypericifolia*, A. Gray (*E. nutans*, Lag.), and *E. maculata*, L., are said by Zollickoffer to be a valuable remedy in *dysentery*, *diarrhœa*, *menorrhagia*, and *leucorrhœa*. (See 16th ed. *U. S. D.*, also *Am. Journ. Med. Sci.*, xi.) Dr. B. J. D. Irwin, U. S. A., states that, under the name of *gollindrinera*, the native Mexican uses the *Euphorbia prostrata*, Ait., in New Mexico and Arizona as a remedy for *snake-bites*. (*Am. Journ. Med. Sci.*, 1861.) In Chili the juice of the *Euphorbia chilensis*, C. Gay (now *E. portulacoides*, L.), is said to be used as a drastic purgative. (*A. J. P.*, 1866, 102.) The juice of the *Euphorbia drummondii*, Boiss., is said in Australia to kill annually a great many sheep and cattle, and in 1886 Dr. John Reid (*Australasian Med. Gaz.*, No. 61) announced the discovery in it of a new anæsthetic alkaloid, *drummine*, which he obtained in colorless crystals almost insoluble in ether, but freely soluble in chloroform and in water. The report of Dr. Alexander Ogsden (*Brit. Med. Journ.*, Feb. 1887) throws, however, very grave doubts upon the anæsthetic power of this new alkaloid. The *E. ocellata*, Durand and Hilgard, of the Pacific coast is used as an antidote for *snake-bites*, and is said to contain 2·82 per cent. of resin, besides gallo-tannic acid; whilst *Euphorbia cremocarpus* of the same region is employed for the purpose of catching fish in still pools and streams, and is said to contain a volatile oil, besides acid and resins. (See *Proc. California Coll. Pharm.*, 1885.) The oil of *E. lathyris*, L., is stated to physiologically resemble croton oil. (*Proc. A. P. A.*, xxvi. 305.)

The *E. heterodoxa*, Muell. Arg., *alveloz* or *aveloz*, a Brazilian species, has been used with asserted extraordinary advantage against *cancerous* and *syphilitic ulcers*. It is a powerful irritant, and even mild caustic. The milky juice, preserved with salicylic acid, or a resin obtained by precipitating with water is employed. The ointment of the resin may be made 3 parts in 100 with vaseline.

Euphorbia pilulifera. L. A prostrate or ascending branched annual, found in almost all tropical countries; is furnished with leaves which are opposite, shortly stalked, ovate to ovate-lanceolate or oblong, from three-quarters to one and a half inches long, denticulate, very oblique and narrow below, or with a semi-cordate base. Stipules minute, linear, inserted on a transverse raised line. The flower-heads are minute, numerous, crowded in head-like

cymes, globular, and are borne on a short stalk in one axil only of each pair of opposite leaves. The involucre is about one-third of a line long, small, entire, and without petal-like appendages. According to De Candolle, the seeds are reddish, acutely oblong, four-sided, and transversely wrinkled, the ridges uniting irregularly. It is to be distinguished from *E. parviflora* (L. ?), which is sometimes substituted for it, by the flower-head of the latter having but few flowers, by the glands of the involucre being furnished with a white, obovate-orbicular appendage, and seeds which are minutely papillose. Levison found in it (*A. J P.*, 1885, 147) several glucoside resins, wax, and volatile matter.

A physiological study of Euphorbia pilulifera led A. Marsset (*T. G.*, 1885) to the conclusion that the active principle acts directly upon the heart and respiration; that it is not an irritant to the skin, but in large dose it is to the gastric mucous membrane. It has been used by Dujardin-Beaumetz and a number of other clinicians with asserted excellent results in the treatment of *asthma* and *asthmatic bronchitis*, also in *chronic bronchitis*, and in *advanced* or *subacute bronchitis*. The best preparation is the fluid extract, the dose of which is from a half to one fluidrachm (1·8–3·6 C.c.) three or four times a day.

EUPHORBIUM. *Euphorbium*, P.G. *Euphorbe, Gomme-résine d'Euphorbe*, Fr. *Euphorbiumharz*, G. The concrete resinous juice of one or more species of Euphorbia (nat. ord. Euphorbiaceæ); but its precise source is uncertain. It has been ascribed to *E. officinalis*, Jack. (now *E. resinifera*, Berg.), growing in the north of Africa and at the Cape of Good Hope, *E. canariensis*, L., a native of the Canary Islands and Western Africa, and *E. antiquorum* (L. ?), inhabiting Egypt, Arabia, and the East Indies, and supposed to be the plant from which the ancients derived this resinous product. These species of Euphorbia bear some resemblance in form to the *Cactus*, having leafless, jointed, angular stems, divided into branches of a similar structure, and furnished with double prickles at the angles. When wounded they yield an acrid milky juice, which concretes on the surface, and constitutes the euphorbium of commerce.

Euphorbium occurs in the shape of tears, or in oblong or roundish masses, about the size of a pea or larger, often forked, and perforated with one or two small conical holes, produced by the prickles of the plant, around which the juice has concreted, and which sometimes remain in the holes. The masses are occasionally large and mixed with impurities. The surface is dull and smooth, bearing some resemblance to that of tragacanth; the consistence somewhat friable, the color light yellowish or reddish; the odor scarcely perceptible; the taste at first slight, but afterwards excessively acrid and burning. The color of the powder is yellowish. The sp. gr. of euphorbium is 1·124. Triturated with water it renders the liquid milky, and is partially dissolved. Alcohol dissolves a larger portion, forming a yellowish tincture, which becomes milky on the addition of water. Its constituents, according to Pelletier, are resin, wax, calcium malate, potassium malate, lignin, bassorin, volatile oil, and water. Brandes found caoutchouc. It contains no soluble gum. The proportions of the ingredients are variously stated by different chemists, and probably vary in different specimens. The most abundant is resin, and the remainder consists chiefly of wax and calcium malate. The resin is excessively acrid, is soluble in alcohol, and, when exposed to heat, melts, takes fire, and burns with a brilliant flame, diffusing an agreeable odor, and has, according to Flückiger, the formula $C_{10}H_{16}O_2$. Flückiger also found a substance analogous to lactucon, which he names *euphorbon*. It is neutral, fusible above 106° C. (223° F.), readily dissolved by boiling alcohol, and soluble in ether, benzin, amylic alcohol, chloroform, acetone, and glacial acetic acid. From its solution in ether and benzin it separates on spontaneous evaporation, in feathery needles. Its solution in sulphuric acid, spread on a plate, is colored violet by nitric acid. Its composition is $C_{18}H_{22}O$. While the acrid resin constitutes 38 per cent. of euphorbium, euphorbon constitutes 22 per cent. (*A. J. P.*, 1868, 393; from *Schweizerische Wochenschrift.*) Hesse (*Ann. Chem. Pharm.*, cxii. 182) has prepared pure euphorbon, and gives it the formula $C_{15}H_{24}O$, fusing point from 113°–114° C., making it isomeric with lactucon. It is lævo-rotatory.

Euphorbium taken internally is a very irritant emetic and cathartic, and in large doses acts as a violent gastro-intestinal irritant poison. In consequence of the severity of its action, its internal use has been entirely abandoned. Applied to the mucous membrane of the nostrils, it excites violent irritation, attended by incessant sneezing and sometimes bloody discharges. Persons who powder it are under the necessity of guarding their eyes, nostrils, and mouth against the fine dust which rises. Largely diluted with wheat flour or starch, it has been used as an errhine in *amaurosis* and *deafness*. Externally applied, it inflames the skin, often producing vesication. It enters into some epispastic preparations, and is especially employed in veterinary practice as a vesicant.

EUPHORIN. *Phenyl Urethane.* $CO<\begin{matrix}OC_2H_5\\NH(C_6H_5)\end{matrix}$. This combination is a white, crystalline powder, melting at 51° C., with a faint aromatic odor, and a taste which, at first scarcely appreciable, subsequently becomes more marked, and resembles cloves; soluble with great difficulty in cold water, very soluble in alcohol and in dilute alcohol. Dr. Sansoni (*Therap. Monatshefte*, Nov. 1890) has found that in enormous doses this drug produces in rabbits collapse, progressive weakness, anæsthesia, and suppression of reflexes. Methæmoglobin is stated never to be found in the blood, though the drug escapes from the body as paramidophenol. Dr. Sansoni has employed euphorin with satisfaction as an antipyretic, antiseptic, analgesic, and antirheumatic. Dose, seven and a half grains (0·48 Gm.), equivalent to fifteen grains (0·97 Gm.) of antipyrin, in capsule or vinous solution.

EUPHRASIA OFFICINALIS. L. *Eyebright. Euphraise*, Fr. *Augentrost*, G. (Nat. ord Scrophularineæ.) A small annual plant, common to Europe and the United States, without odor, and of a bitterish, astringent taste. Enz (*Viertelj. f. Prakt. Pharm.*, viii. 175) obtained a little volatile oil, an acrid and bitter principle, mannite and glucose, and a tannic acid, the lead salt of which showed on analysis the formula $C_{32}H_{20}O_{17}.5PbO$ and had a bright green color. It was formerly used in *toothache*. G. M. Garland (*A. J. P.*, 1890) states that ten drops of a concentrated tincture every two hours is a specific in acute *nasal catarrh*.

EUPHTHALMINE HYDROCHLORIDE. This is the mandelic acid derivative of Eucaine B,

just as homatropine is the mandelic acid derivative of the base tropine. A permanent snow-white crystalline powder, very soluble in water and soluble in about two parts of boiling absolute alcohol, separating again on addition of ether in crystalline aggregates. The salt is anhydrous; it melts at from 183°–184° C. and begins to run together at 181° C. The salicylate, $C_{17}H_{25}O_3N,C_6H_4(OH)COOH$, prepared by mixing ether solutions of the base and of salicylic acid, and recrystallizing from absolute alcohol and ether, melts at from 115°–116° C. and is very readily soluble in water. The *hydrochlorate* of the unstable *n-methyl-vinyl-diacetone-alkamine* is a colorless crystalline powder, freely soluble in water, to which Treutler and Vossius have called attention as a powerful local mydriatic. From two to three drops of a 2 per cent. solution will produce in from twenty to thirty minutes pronounced mydriasis, which disappears after two or three hours (seven hours, Winselmann) and is not accompanied by pain or other unpleasant secondary effects. There is no irritation of the cornea, or local anæsthesia, and accommodation is said to be less affected than with the mydriatics in common use. (*Therap. Wochenschr.*, 1897; *Berichte*, xxxi. 665; *Pharm. Journ.*)

EUQUININE. *Quinine Ethyl Carbonic Ether.* $CO<^{O.C_2H_5}_{O.C_{20}H_{23}N_2O}$. Euquinine is made by the action of chloro-carbonic ethyl-ether on quinine. It occurs in the form of fine needle-like white crystals, melts at 95° C., is scarcely soluble in water, but easily so in alcohol, ether, and chloroform. It forms crystalline salts. A solution in sulphuric or nitric acid fluoresces with a blue color like quinine. The thalleioquin reaction of euquinine is the same as that of quinine, but there is no herapathite reaction. The euquinine hydrochlorate dissolves readily in water, the sulphate much less easily, while the tannate is almost insoluble.

It has been alleged that it is possible by the use of euquinine to obtain the beneficial effects of quinine without unpleasant accompaniments of cerebral congestion and irritation, although tinnitus aurium is produced. Euquinine has been employed with asserted satisfactory results by C. von Noorden (*Centralb. f. Innere Med.*, 1896) in *pneumonia*, *pleurisy*, and various other acute diseases, as a substitute for quinine; and the results have been confirmed by Goliner (*Allge. Med. Central-Zeitung*, 1897) and by Overlach (*Deutsche Med. Ztg.*, 1897); whilst Panegrosso (*Gaz. degli ospedali*, Oct., 1897) has used it in *malaria* with results which seem to have been decided but inferior to those obtainable with quinine. The necessary doses are larger than those of quinine; in ordinary acute diseases thirty grains may be given daily; in malaria forty grains.

EUROBIN. *Chrysarobin triacetate* is used as a substitute for chrysarobin; it is soluble in chloroform, acetone, and ether, insoluble in water.

EUROPHEN. *Di-isobutyl-ortho-cresol-iodide.* $2\left(\begin{matrix}C_4H_9\\CH_3\end{matrix}\right\}C_6H_3O\Big)HI$. This is a yellow amorphous powder, of a specific aromatic odor, which has been proposed as a substitute for iodoform. It contains 28·1 per cent. of iodine. It is asserted that it is five times lighter than iodoform, and can be used in much larger bulk; that it is equally efficacious with iodoform; also that it is decomposed more slowly than iodoform, and is, therefore, less poisonous. (See *Pharm. Zeitung*, July, 1891; also *Therap. Monats.*, July, 1891.) This substance is made by the action of iodine upon isobutylorthocresol in a solution of potassium iodide. It occurs as a fine, soft, amorphous powder, light yellow, tasteless, and having but a faint odor. It is soluble in ether, chloroform, collodion, alcohol, and fixed oils; insoluble in water and glycerin; melting at 230° F. Its solution undergoes decomposition when exposed to light or heat.

Europhen contains about 28 per cent. of iodine, which element is slowly liberated from its alcoholic and ethereal solutions. It is incompatible with metallic oxides and mercurial salts, and undergoes slight change in the presence of organic matter. Taken internally it is said to pass out in great part from the alimentary canal with the fæces unchanged, though some absorption takes place. It is asserted that it is non-toxic, two or three drachms having been given to dogs and fifteen grains to human beings without effect. As a microbicide it is affirmed to be about equivalent to iodoform. (*Revue Méd. de l'Est*, Feb. 1892.)

It has been used by a number of clinicians with asserted good results as a local application to *chancres*, *syphilitic ulcers*, *burns*, *psoriasis*, *eczema*, *lupus*, and various *skin diseases*. It is usually applied in an ointment varying in strength, according to the individual cases, from 1 to 10 per cent. A stronger ointment is distinctly irritant. It has also been employed in *rhinitis*, *laryngeal tuberculosis*, and other inflammatory disorders of the preliminary air-passages. Internally it has been used, especially hypodermically, dissolved in oil, in *constitutional syphilis*, with not very encouraging results. Dose, from a half to one and a half grains (0·03-1·1 Gm.),

Under the name of *europhen-aristol* a mixture of europhen and aristol has been put upon the market.

EURYBIN. A glucoside obtained from a New Zealand plant, *Eurybia moschata*. (*Merck's Bericht*, 1893, 12.)

EVODIA. Several species of this genus are stated to have medicinal properties. *E. febrifuga* of Brazil is astringent and tonic, *E. glauca* of Japan contains berberine, whilst *E. longifolia* of the Feejee Islands is to prevent abortion.

EXALGINE. *Methylacetanilid.* $C_6H_5N(CH_3)COCH_3$ or $C_9H_{11}NO$. This substance, which was discovered by Brigonnet, is one of the three isomeric methyl derivatives of acetanilid (*Compt.-Rend.*, cviii. 571), and is made by warming together monomethylaniline and acetylchloride. It occurs in needles, or in long tablet-like crystals, according as it is obtained by crystallization or from the mass after fusion. It is sparingly soluble in cold water, quite soluble in hot water, and readily soluble in very dilute alcohol, or in water to which a small amount of alcohol has been added; it fuses at 101° C., and boils between 240° and 250° C. without decomposition. The hot aqueous solution is said by Upton to retain most of its exalgine on cooling.

According to Dr. Brigonnet, hypodermic injections of exalgine produce in the lower animals violent epileptiform convulsions, profuse salivation, cyanosis, disturbance of breathing, fall of temperature, and alteration of the blood, which becomes dark prune-colored and contains an abundance of methæmoglobin. The muscles at the seat of the injection are said to be locally paralyzed, and

although small doses increase slightly the blood-pressure, after the toxic dose the pressure suddenly falls. The urine does not become albuminous or bloody. When given to man in full, non-poisonous doses, it produces some slight amblyopia, vertigo accompanied in some patients by vomiting, tinnitus aurium, headache, drowsiness, and vaso-motor disturbances, such as sweating. After large doses, cyanosis is pronounced, but no eruption upon the surface of the skin seems as yet to have been noticed. No fatal poisoning by it has been reported, but in a case of Mr. A. C. Hartley's, eighteen grains in divided doses produced a general motor paralysis, with dyspnœa, intense pallor, dilated pupils, and pronounced palpitation of the heart. In a second case, two doses of three grains each produced in a boy fourteen years old a sudden almost lethal heart-failure, with dilated pupils and dyspnœa. In a case reported by Gillespie (*Med. Press and Circ.*, March, 1892) there were violent convulsions. (See also *Bull. de Thérap.*, March, 1891, and *Brit. Med. Journ.*, Feb. 1890.)

Therapeutically, exalgine seems to be an antipyretic, but it has been used almost exclusively as an analgesic and antispasmodic; it being claimed for it that as such it acts much more certainly and powerfully than antipyrin and other drugs of this class. According to Moncorvo, it is very well borne in children; he has used it extensively in *chorea*, *polyuria*, and for the relief of *pain*. He believes that its analgesic effect is at least five times as strong as that of antipyrin; his dose, to a child five years old, is one and a half grains. The dose for the adult is from three to six grains (0·194–0·389 Gm.), not more than twelve grains being administered in the twenty-four hours, and the smaller dose being always used at first.

EXODYNE. A commercial compound said by Goldman to consist of acetanilid 90 per cent., sodium bicarbonate 5 per cent., and sodium salicylate 5 per cent. It is used as an antipyretic.

EXTRACTUM CARNIS. *Extract of Flesh. Extract of Meat. Extract of Beef. Extrait de Viande de Liebig*, Fr. *Liebig's Fleischextrakt*, G. The object of this preparation is to obtain the nutritive matters of the flesh of animals in a concentrated state, in which they may be long kept without change. Two great advantages are thus gained, cheapness of carriage, and the facility of transfer from places, however remote, where meat is plentiful, to others where it is most needed. Thus, the cattle so abundant on the plains of South America, Australia, and Russia may be made to contribute to the support of the people of Europe and North America; and this object has already been in some degree accomplished, as factories are in operation in these regions by which, in the condition of *extract of flesh*, beef is very largely prepared; and South American extract of beef is well known all over the world. Though to Liebig belongs the credit of setting this movement on foot, and his process is probably most extensively used, others have employed processes of their own, and some are perhaps equal if not superior to his.

Liebig's extract of beef, besides what is made by various independent operators, who, employing his process, take advantage of the popularity of his name in spreading their products abroad, is now very largely prepared by a company which, under his supervision, established itself in South America. For methods of preparation, see 16th ed. *U. S. D.* It is said that 100 parts of meat yield 2·5 of extract. The preparation keeps well, contains neither fat nor gelatin, and is rich in the nitrogenous principles. It is of a reddish-brown color, a slightly acrid taste, and an odor that is not agreeable; so that when dissolved in hot water to make soup, it is necessary, in order to make a savory dish, to add leguminous fruits to the extract. To avoid this flavor it would be necessary to effect the evaporation out of contact with the air, and if possible altogether in a vacuum. The varying quality of the extract is ascribed, in part at least, to the character of the meat.

Essence of Beef, or *Beef tea*, and *Essence of Mutton* are similar in their powers to the extracts, but are much preferable to them. They may be used with advantage as stimulants in low fevers, etc., in doses of from half an ounce to two ounces, and are prepared as follows. The flesh, having been deprived as far as possible of fatty matter, and cut into very small pieces, is introduced without water into a convenient long-necked bottle (a common quart porter-bottle will answer the purpose very well) until this is filled; the bottle is then placed upright

in a pot of boiling water, so that the top of the bottle shall be above the surface of the liquid, and is exposed to a boiling heat for an hour or more, the mouth of the bottle being closed with a cork so tightly as to prevent the escape of vapor, but not so as to endanger the breaking of the vessel. At the end of the process the liquid is to be poured out of the bottle, and, when sufficiently cool, is ready for use.

Under the name of *Johnston's Fluid Beef*, a preparation, made in Philadelphia, has been introduced, which differs from other extracts in the fact that albumin is replaced by the finely powdered dried residue of the meat; the muscular fibre is plainly visible under the microscope. The name *fluid* beef is a misnomer, as it is of extractiform consistence; it is, however, a good extract. *Wyeth's Beef Juice* is a dark red fluid, sp. gr. 1·225, with an acid reaction, which, when mixed with cold water, forms an unaltered brownish-red liquid. When heated, albumin is separated, a pulpy mass being formed. Fresenius's analysis shows that it contains of organic substances 25·61 per cent., mineral constituents 15·54 per cent., water 58·85 per cent., the organic substances being composed of nitrogenous substance 19·95 per cent., fat ·065 per cent., lactic acid ·604 per cent., nitrogen-free substances 4·991 per cent.; the mineral constituents are mainly sodium and potassium chlorides and phosphates.

For a table of analyses of some of the best-known meat preparations, mainly from A. Stutzer, see p. 1654. (*Rep. Anal. Chem.*, v. 217, 218.)

The extract of meat by no means represents the nutritive qualities of the meat itself, as the two most nutritious ingredients of flesh, albumin and fibrin, are usually wanting; and efforts are made as far as possible to get rid of fat, and in most instances of gelatin also, though, in relation to the latter principle, with, in our opinion, questionable propriety. In low fevers it is recommended by some as possessing, in addition to its slightly nutritious qualities, the somewhat stimulant properties characteristic of the meat essences.

FABIANA IMBRICATA. Ruiz and Pavon. *Pichi.* (Nat. ord. Solanaceæ.) This is a shrub growing in Chili and the Argentine Republic, attaining the height of about six feet, with its smaller branches covered with very thick, almost scale-like, ovate leaves, about one-twelfth of an inch in length, having their bases and margins whitened with a resinous deposit. The appearance of the plant is almost that of a conifer, but it has white flowers. The wood is uniformly yellowish, hard, heavy, and very fine grained. The thin bark is light gray, minutely roughened by small, sharp, longitudinal ridges, and minute gland-like protuberances, which exhibit under the lens a peculiar resinous lustre. For microscopic structure, see *Proc. A. P. A*, 1889.

Dr. A. B. Lyons first obtained a fluorescent body resembling æsculin, a neutral crystalline principle, some volatile oil, resin, and apparently traces of an alkaloid. (*A. J. P.*, 1886, 65.) G. A. Deitz succeeded in crystallizing the fluorescent principle, but found no alkaloid. He also obtained the neutral crystalline principle referred to, but did not examine it further. This was done by Henry Trimble and J. M. Schroeter (*A. J. P.*, 1889, 407), who considered it to be a resin, and gave it the formula $(C_{18}H_{31}O_2)x$. It crystallizes in white acicular needles from hot alcohol, turns brown at 240° C., and decomposes without melting at 270° C. H. C. Loudenbeck (*A. J. P.*, 1891, 432) examined the fluorescent principle, and found it to be a glucoside. It forms light, nearly white crystals, which have a bitter taste, fluoresce intensely blue with ammonia, changing to a paler rose fluorescence with acids, melt at 180° C. to a yellow liquid, and decompose at a slightly higher temperature.

Pichi appears to be a terebinthinate diuretic, to which also are attributed tonic and cholagogue properties. It has been used to a considerable extent in the treatment of *acute* and *chronic vesical catarrh*, giving especially favorable results in cases in which the urinary irritation is kept up by *gravel*. It is said even to calm the irritability and aid in the expulsion of *renal*, *urethral*, or *cystic calculi*. It has been further recommended in the treatment of *jaundice* and *dyspepsia*, with lack of biliary secretion. It is somewhat irritating, and is usually said to be contra-indicated by the existence of organic disease of the kidneys; but cases have been reported in which *renal hemorrhage* connected with Bright's disease has been greatly benefited by the remedy. It has also been employed in *gonorrhœa* and in *gonorrhœal prostatitis*. The solid extract may be used in the dose of from two to ten grains (0·13–0·65 Gm.); the fluid extract, in the dose of from ten to forty minims (0·6–2·5 C.c.). It is probable that the resinoid precipitate, made from a strong tincture by means of water, would be the best preparation of the drug. The fluid extract does not mix with water unless the solution be made alkaline. It may be administered in capsules or aromatized emulsion.

FARINA TRITICI. Under this name the Br. Pharmacopœia formerly recognized ordinary wheat flour. *Bran* is the husk separated from the wheat during the process of grinding, and constitutes from 25 to 33 per cent. of the whole yield.

Flour is white, inodorous, and nearly insipid. Its chief constituents are starch, gluten, albumen, saccharine matter, and gum, the proportions of which are not constant. Clifford Richardson (*Bulletin No. 9, U. S. Department of Agriculture*, 1886) gives as the average of 27 analyses of wheat the following composition: moisture, 9·25; ash, 1·84; oil, 2·30; sugar, 3·50; dextrin and soluble starch, 2·30; starch, 67·88; albuminoids soluble in 80 per cent. alcohol, 3·58; albuminoids insoluble in 80 per cent. alcohol, 7·45; fibre, 1·90; total, 100. The gummy substance found in wheat flour is not precisely identical with ordinary gum, as it contains nitrogen, and does not yield mucic acid by the action of nitric acid. The starch, which is by far the most abundant ingredient, is much employed in a separate state. (See *Amylum*.) The gluten, however, is not less important, as it is to the large proportion of this principle in wheat flour that it owes its superiority over that from other grains for the preparation of bread. The gluten here referred to is the substance first noticed as a distinct principle by Beccaria. It is the soft, viscid, fibrous mass which remains when wheat flour enclosed in a linen bag is exposed to the action of a stream of water and at the same time pressed with the fingers till the liquor comes away colorless. But this has been ascertained to consist, in fact, of two different substances. When boiled in alcohol, one portion of it is dissolved, while another remains unaffected. Einhof ascertained that the part of the glutinous mass left behind by

alcohol is identical with *vegetable albumen*, while the dissolved portion only is strictly entitled to the name of *gluten*, which had been previously applied to the whole mass. As these two principles are contained in numerous vegetable products, and as they are frequently referred to in this work, it is proper that they should be briefly noticed. They both contain nitrogen, and both, when left to themselves in a moist state, undergo putrefaction. From these circumstances, and from their close resemblance to certain proximate animal principles in chemical habitudes and relations, they were sometimes called, in old works on chemistry, *vegeto-animal substances*. They are separated from each other by boiling the gluten of Beccaria, above referred to, with successive portions of alcohol, till the liquid, filtered while yet hot, ceases to become turbid on cooling. The proper gluten dissolves, and may be obtained by adding water to the solution and distilling off the alcohol. Large cohering flakes float in the liquor, which, when removed, form a viscid, elastic mass, consisting of the substance in question with slight impurity. The part left behind by the alcohol is coagulated albumen.

Pure *gluten*, sometimes called *vegetable fibrin*, is a pale yellow, adhesive, elastic substance, which by drying becomes more deeply yellow and translucent. It is almost insoluble in water, and quite insoluble in ether and in the oils, both fixed and volatile. Hot alcohol dissolves it much more readily than cold; and from its solution in boiling alcohol it separates unchanged when the liquor cools. It is soluble in dilute acids, and in caustic alkaline solutions, in consequence of forming soluble compounds with the acids and alkalies. With the earths and metallic oxides it forms nearly insoluble compounds, which are precipitated when earthy or metallic salts are added to the solution of gluten in solution of potassa. Corrosive sublimate precipitates it from its acid as well as alkaline solutions, and, added in solution to moist gluten, forms a compound with it, which, when dry, is hard, opaque, and incorruptible. Gluten is precipitated by infusion of galls. Its name originated in its adhesive property. It exists in most farinaceous grains and in the seeds of some leguminous plants.

Vegetable albumen is destitute of adhesiveness, and, when dried, is opaque and of a white, gray, or brown color. Before coagulation, it is soluble in water, but insoluble in alcohol. By heat it coagulates and becomes insoluble in water. It is dissolved by solutions of the caustic alkalies. Most of the acids, if added to its solution in excess, precipitate compounds of the acids respectively with the albumen, which, though soluble in pure water, are insoluble in that liquid when acidulated. It is not, however, precipitated by an excess of phosphoric or acetic acid. Its relations to the earthy and metallic salts are similar to those of gluten. Corrosive sublimate precipitates it from its solutions, except from those in phosphoric and acetic acids, and, when added in a state of solution to moist albumen, forms with it a hard, opaque compound. It is also precipitated by infusion of galls. This principle derived its name from its very close resemblance to animal albumin. It is associated with gluten in most of the farinaceous grains, is a constituent of all the seeds which form a milky emulsion with water, and exists in all the vegetable juices which coagulate by heat.

The mixture of vegetable fibrin and albumen which constitutes the gluten of Beccaria exercises an important influence over starch, which, with the presence of water, and the aid of a moderate heat, it converts partly into gum and partly into sugar. The production of saccharine matter in the germination of seeds, and in malting, which is an example of germination, is thus explained. The gluten becomes acid in the process, and loses the property of reacting on starch.

It is thought by some chemists that *vegetable albumen* is identical in all respects with *animal albumin*, and the *gluten* of vegetables with animal *fibrin*, and that both these principles, as well as another named *casein*, found also both in the animal and in the vegetable kingdom, belong to a class of compounds termed *proteids*. *Proteids* consist of nitrogen, carbon, hydrogen, oxygen, and sulphur, and their average composition may be expressed by the empirical formula $C_{72}H_{112}N_{18}O_{22}S$.

A poisonous alkaloid has been detected by Mr. Ballaud in flour which had been kept in sacks for twelve or eighteen months. (*P. J. Tr.*, 1885, 868.)

It is scarcely necessary to state that bread is formed by making flour into a paste with water, with the addition of yeast, setting it aside to ferment, and then exposing it to the heat of an oven. The fermentation excited by the yeast is accompanied by the extrication of carbonic acid gas, which, being retained by the tenacity of the gluten, forms innumerable little cells throughout the mass, and thus renders the bread light.* Alcohol is also generated during the fermentation, most of which is driven off from the bread in baking; but a small portion remains, averaging, according to Mr. Thos. Polas, 0·314 per cent. (*Chem News*, May 30, 1873.)

Medical Properties and Uses. Wheat flour in its unaltered state is seldom used in medicine. It is sometimes sprinkled on the skin in erysipelatous inflammation, and in various itching or burning eruptions, particularly the nettle-rash; though rye flour is generally preferred for this purpose.

Bread is more employed. An infusion of toasted bread in water is a nutritive drink well adapted to febrile complaints. Within our experience, no drink has been found more grateful in such cases than this infusion, sweetened with a little sugar,

* *Adulteration of bread.* Among the adulterations of bread practised by the bakers, alum, employed to cause whiteness and thus cover defects in the flour, is perhaps the one which has most attracted notice, and which, being sometimes noxious, it is most important to be able to test. One of the means of detection recommended is that of incineration, by which the bread is consumed, while the alum, if there be any, is left behind. But this method is somewhat tedious; and logwood has been recommended as being at once most convenient and, according to Mr. John Horsley, "*perfectly reliable*," if applied as he directs. The following is Mr. Horsley's method, by which in the county of Gloucester, England, alone, in the course of two surveys, he succeeded in obtaining two hundred convictions out of some thousands of cases examined by him. He first makes a tincture of logwood by digesting, for eight hours, two drachms of freshly cut chips in five ounces of methylated spirit and filtering; next makes a saturated solution of ammonium carbonate in distilled water; then mixes a teaspoonful of each solution with a wineglass of water in a white-ware dish, thus forming a pink-colored liquid; and lastly immerses a portion of the suspected bread, "for five minutes or so," in the mixed fluids. If alum be present, the bread, placed on a plate to drain, will in the course of an hour or two assume a blue color; if not present, the pink color will fade away. The appearance of a greenish color on drying will indicate the presence of copper. (*Chem. News*, May 17, 1872, p. 1872.) For some modifications of this method by Herz, see *Archiv de Pharm.*, 1886, 676.

and flavored by lemon-juice. Boiled with milk, bread forms a good emollient poultice, which may be improved by the addition of a little perfectly fresh lard. Slices of it steeped in lead water, and the crumb mixed with the fluid and confined within gauze, afford a convenient mode of applying this preparation to local inflammations. The crumb (*mica panis*) is, moreover, frequently used to give bulk to minute doses of very active medicines administered in the form of pill. It should be recollected that it always contains common salt, which is incompatible with certain substances, as, for example, silver nitrate.

Bran is sometimes used in decoction, as demulcent in catarrhal affections and complaints of the bowels. When taken in substance, it is laxative, and may be used with advantage to prevent costiveness. Bran bread, made from the unsifted flour, is an excellent laxative article of diet in some dyspeptic cases. The action of the bran is probably mechanical, consisting in the irritation produced upon the mucous membrane of the bowels by its coarse particles. Bran also forms an excellent demulcent bath.

FERRATIN. This is a light brown powder containing from 6 to 8 per cent. of iron in a form soluble in alkaline liquids. It is an albuminous compound, originally prepared by Schmiedeberg from the liver of the hog, and believed to be the natural compound of iron as it exists in the system, and therefore of especial value in therapeutics. It is now made by the reaction of the albumin with a double tartrate of iron and an alkali. It is almost insoluble in water, soluble in alkalies, and contains 7 per cent. of iron in organic compounds. Soluble sodium ferratin has also been put upon the market.

Ferratin may be given in doses of from three to five grains (0·19–0·3 Gm.) three times a day. It appears to be capable of acting as a chalybeate, but there is no sufficient reason for believing it to be superior to the older preparations of iron.

FERRI ALBUMINAS. *Ferric Albuminate.* This preparation has come into some prominence, more particularly in Europe, on account of its asserted advantages over various other compounds of iron, Démarquay, Chrisnard, and others recommending its employment in chlorosis and anæmia as being more readily absorbed. Friese, Kobligk, Bernbeck, Biel, Holdermann, Nierck, Donitz, and Hager have each proposed methods for preparing either the solution or dry salt. Prof. C. L. Diehl, however, after a careful review of the processes of these investigators, offers the following. 4 troy-ounces of white of eggs are diluted with 8 fluidounces of water; 50 minims of official solution of ferric chloride diluted with 4 fluidounces of water are added, and the solution filtered. The filtrate is now mixed with 10 fluidounces of a saturated solution of sodium chloride, the precipitate collected on a wet muslin strainer, washed with a mixture of 1 volume of the saturated solution of sodium chloride and 3 volumes of water, until the washings give but a faint reaction for iron. The washed ferric albuminate is, after draining, powerfully pressed to get it as dry as possible, and then exposed to a dry atmosphere, and finally powdered. This salt contains the equivalent of 5 per cent. of ferric oxide, or 10 per cent. of ferric chloride. For other processes, see *A. J. P.*, 1880, 177. As thus obtained, ferric albuminate is a cinnamon-brown powder, having a slight taste of common salt (due to the presence of a small quantity), soluble in water, particularly if slightly acidulated with hydrochloric acid. It is best administered in doses of from twenty to thirty grains (1·3–1·95 Gm.) in simple aqueous solution, which should be freshly prepared. It may also be given in the form of a pill, either alone or combined with strychnine, quinine, etc. For method of preparing *iron and potassium albuminate*, and *iron and sodium albuminate*, see 16th ed. *U. S. D.*

FERRI BROMIDUM. *Bromide of Iron. Ferrum Bromatum. Bromure ferreux*, Fr. *Eisenbromür, Ferrobromid*, G. $FeBr_2$. This bromide is obtained by heating gently, in thirty parts of water, two parts of bromine and one of iron filings. When the liquid has become greenish, it is filtered and evaporated to dryness in an iron vessel; and the dry mass, again dissolved and evaporated to dryness, furnishes the bromide. Ferrous bromide is a yellowish, deliquescent salt, very soluble, and extremely styptic. For medical employment it should be in aqueous solution, protected by sugar. Mr. Dillwyn Parrish has proposed the following formula. Take of bromine two hundred grains; iron filings eighty-five grains; distilled water four and a half fluidounces; sugar three ounces. Make a solution in the manner directed for preparing solution of ferrous iodide. (See *Ferri Iodidum.*) For other formulas, see *P. J. Tr.*, 3d ser., v. 67, 162. This solution has been used with alleged success as an alterative tonic in *chorea*, and in various *scrofulous* and *erysipelatous affections.* (See 16th ed. *U. S. D.*) The dose of ferrous bromide is from one to three grains (0·064–0·19 Gm.), three times a day, gradually increased until its effects are manifested.

FERRI ET BISMUTHI CITRAS. *Iron and Bismuth Citrate.* A solution of this so-called salt has been used in *dyspepsia.* It is made by dissolving bismuth citrate in an aqueous solution of ammonia, and adding the ferric ammonio-citrate. It is a mere mixture. (*A. J. P.*, xliv.)

FERRI ET MAGNESII CITRAS. *Iron and Magnesium Citrate.* This double salt, introduced by Van der Corput, is made by dissolving two ounces of freshly precipitated ferric hydrate in a moderately heated solution of three ounces of citric acid, and saturating the liquor with magnesium carbonate. The solution, after filtration, is evaporated by means of a water-bath to a syrupy consistence, and spread on glass to dry in scales. Three and a quarter ounces of ferrous sulphate will furnish by decomposition the necessary hydrated oxide for three ounces of the acid. (See formula for *Ferri Oxidum Hydratum.*) This salt is in transparent, greenish-yellow scales, having a slightly ferruginous, somewhat acid taste. It is very soluble in water, but insoluble in alcohol and ether. Dose, from five to ten grains (0·323–0·647 Gm.). (See *A. J. P.*, 1850, 315.)

FERRI IODIDUM. *Iodide of Iron. Ferrous Iodide. Ferrum Iodatum*, P. G. *Iodure de Fer*, Fr. *Eisenjodür, Jodeisen*, G.

"Take of Fine Iron Wire *one ounce and a half* [avoirdupois]; Iodine *three ounces* [avoird.]; Distilled Water *fifteen fluidounces.* Put the Iodine, Iron, and twelve [fluid] ounces of the Water into a flask, and, having heated the mixture gently for about ten minutes, raise the heat and boil until the froth becomes white. Pass the solution as quickly

as possible through a wetted calico filter into a dish of polished iron, washing the filter with the remainder of the Water, and boil down until a drop of the solution taken out on the end of an iron wire solidifies on cooling. The liquid should now be poured out on a porcelain dish, and, as soon as it has solidified, should be broken into fragments, and enclosed in a well-stoppered bottle." *Br.* 1867.

The solid ferrous iodide in its unprotected state is omitted in the present editions of the U. S. and Br. Pharmacopœias. The former directs it in pills and syrup prepared immediately from the materials, and as *Ferri Iodidum Saccharatum.* The iodide is extremely liable to spontaneous change.

In the Br. process of 1867, which is a modification of that of the late Dublin Pharmacopœia, iron is made to unite with iodine by the intervention of water, and the combination takes place readily and quickly. The liquid at first is red or orange colored, from the circumstance that all the iodine has not united with the iron; but, after the application of heat, it becomes fully saturated and limpid, and assumes a greenish color. It is now a solution of ferrous iodide, and yields the solid salt by evaporation. The proportion of the iron taken is half the weight of the iodine. Fine iron wire, recently cleaned, is directed on account of its purity; but iron filings dissolve more readily, and, if carefully selected, will be sufficiently pure. It is exceedingly difficult to obtain the salt in the solid state perfectly pure, so great is the proneness of its solution to absorb oxygen, whereby the iodide becomes, in part, converted into sesquioxide. This change is prevented to a certain extent by evaporating to dryness in an *iron* vessel.

The Messrs. T. & H. Smith, of Edinburgh, recommended the following improved process, which more effectually excludes atmospheric air. Boil, in a Florence flask, six drachms of pure iron filings with two ounces and a quarter of iodine, in four and a half ounces of distilled water, until the liquid loses its dark color. Then filter the liquid rapidly into another flask, and evaporate it, at a boiling heat, until its green shade passes into black. After this period, the heat is kept up as long as the evaporation of moisture continues, which may be ascertained by its condensation on a cold piece of glass, placed, from time to time, over the mouth of the flask. When this ceases, the flask contains pure, anhydrous, spongy ferrous iodide, which, when cold, is to be removed by breaking the flask, bruised coarsely in a warm dry mortar, and enclosed immediately in small well-corked bottles. If it be wished to obtain the iodine as a crystallized hydrate, the heat is to be withdrawn as soon as the liquid is sufficiently concentrated to congeal, in a dry and hard crust, on the end of an iron wire dipped into it. A modification of this process by Dr. Squibb will be found in *A. J. P.*, 1859, 52. *Iron Iodates* have been used to some extent as therapeutic agents in Dublin. For formulas for their preparation, see *P. J. Tr.*, i. 624.

Ferrous iodide is a crystalline substance, exceedingly deliquescent, of a greenish-black color, and styptic, chalybeate taste. Its solution, by evaporation with as little contact of air as possible, affords transparent, green, tabular crystals. When heated moderately it fuses, and, on cooling, becomes an opaque crystalline mass, having an iron-gray color and metallic lustre. At a higher temperature it emits violet-colored vapors, and the iron is left in the state of sesquioxide. It is very soluble both in water and in alcohol. When recently prepared it is wholly soluble in water, forming a pale green solution; but, if made for some time, it almost unavoidably contains some ferric oxide, from a partial decomposition, and will not entirely dissolve. M. Lecocq, of Saint-Quentin, has proposed to preserve it in a wide-mouthed, ground-stoppered bottle, covered with a layer of reduced iron, which cannot decompose it, and protects it from the action of the air. When the iodide is wanted, the iron is removed with a bone spatula or a little brush. The aqueous solution is very liable to spontaneous decomposition, becoming at last orange-red from the generation of free iodine, and depositing ferric oxide. According to Mr. Richard Phillips, Jr., the first step in this change is the formation of ferrous oxide and hydriodic acid, from the decomposition of water. As the ferrous oxide immediately begins to be converted into ferric oxide by absorbing oxygen from the air, and in this state is precipitated, the hydriodic acid is set free; and hence is explained the acidity of the solution from the first moment the ferric oxide is deposited. Afterwards, the hydriodic acid is decomposed by the air, and iodine liberated. When the solution is prevented from generating free iodine, by placing in it a coil of iron wire, according to the plan of Mr. Squire, the iron acts by combining with the iodine of nascent hydriodic acid, and not with nascent iodine. (*P. J. Tr.*, iv. 19.) The plan of Mr. Squire does not prevent the deposition of ferric oxide, and has, therefore, been superseded by the use of saccharine matter, which affords a better protection to the solution. (See *Syrupus Ferri Iodidi.*) Ferrous iodide is incompatible with alkalies and their carbonates, with lime water, and with all other substances by which ferrous sulphate is decomposed. When crystallized, it has the composition $FeI_2.5H_2O$.

Ferrous iodide was first employed in medicine by Dr. Pierquin in 1824. It was first used in the United States in 1832 by the late Prof. Samuel Jackson. Its powers are those of a tonic, alterative, and diuretic. It acts more like the preparations of iron than like those of iodine. It sometimes sharpens the appetite and promotes digestion, and occasionally proves laxative. When it does not operate on the bowels, it generally augments the urine. Its use blackens the stools and lessens their fetor. It is chiefly employed in *scrofulous complaints, swellings of the cervical glands, chlorosis, atonic amenorrhœa,* and *leucorrhœa.* In *secondary syphilis,* occurring in debilitated and scrofulous subjects, Ricord has found it a valuable remedy. The dose is a grain (0·065 Gm.), gradually increased to eight grains (0·52 Gm.).

This salt, on account of its deliquescent property and proneness to decomposition, should not be given in pill, unless protected from change by saccharine matter or other means. (See *Pilulæ Ferri Iodidi,* p. 1046 and *Ferri Iodidum Saccharatum,* p. 620.) The most convenient form of exhibition is that of syrup or glycerate.*

* *Glycerate of Ferrous Iodide.* Glycerin has the property at once of dissolving and preserving ferrous iodide, and therefore makes an excellent excipient. M. Veza proposes the following formula. "Take of Iodine 70 parts, Iron, in powder, 35 parts, and Glycerin 400 parts. Mix them." The color of the solution is an emerald-green; its taste is bitter and astringent; and tests do not detect in it the presence of free iodine. It may be used for preparing the syrup or pills. Five grains of it contain one of ferrous iodide.

FERRI OXALAS. *U. S.* 1880. *Oxalate of Iron. Ferrous Oxalate.* $FeC_2O_4.H_2O$; 161·62. *Ferrum Oxalicum. Oxalas Ferrosus. Oxalate de Fer*, Fr. *Oxalsaures Eisenoxydul*, G.

"Take of Sulphate of Iron *two troyounces;* Oxalic Acid *four hundred and thirty-six grains;* Distilled Water *a sufficient quantity.* Dissolve the Sulphate of Iron in thirty fluidounces, and the Oxalic Acid in fifteen fluidounces of Distilled Water, filter the solutions, and, having mixed them with agitation, set aside the mixture until the precipitate is deposited. Decant the clear liquid, wash the precipitate until the washings cease to redden litmus, and dry it with a gentle heat." *U. S.* 1870.

This salt was made official in 1870, and was very properly dropped in 1890, as it is a very feeble, inefficient chalybeate. "A pale yellow, or lemon-yellow, crystalline powder, permanent in the air, odorless and nearly tasteless, very slightly soluble in cold or hot water, but soluble in cold, concentrated hydrochloric acid, and in hot diluted sulphuric acid. When heated in contact with air, it decomposes with a faint combustion, and, on ignition, leaves a residue, amounting to not less than 49·3 per cent. of the original weight. On heating the salt with excess of test-solution of carbonate of sodium, it is decomposed, yielding a precipitate which, when dissolved in diluted hydrochloric acid, affords a blue precipitate with test-solution of ferricyanide of potassium, and a filtrate which, when supersaturated with acetic acid, yields, with test-solution of chloride of calcium, a white precipitate soluble in hydrochloric acid." *U. S.* 1880. Dose, from two to three grains (0·13–0·20 Gm.).

FERRI OXIDUM MAGNETICUM. *Magnetic Iron Oxide. Martial Ethiops. Ferrum Oxydatum Magneticum. Oxydum Ferroso-Ferricum. Black Iron Oxide. Oxyde de Fer noir (magnétique), Oxyde ferroso-ferrique*, Fr. *Magneteisen, Eisenoxyd Oxydul*, G.

"Take of Solution of Persulphate of Iron *five and a half fluidounces* [Imperial measure]; Sulphate of Iron *two ounces* [avoirdupois]; Solution of Soda *four pints* [Imp. meas.]; Distilled Water *a sufficiency.* Dissolve the Sulphate of Iron in *two pints* [Imp. meas.] of the Water, and add to it the Solution of Persulphate of Iron, then mix this with the solution of Soda, stirring them well together. Boil the mixture, let it stand for two hours, stirring it occasionally, then put it on a calico filter, and, when the liquid has drained away, wash the precipitate with Distilled Water, until what passes through the filter ceases to give a precipitate with chloride of barium. Lastly, dry the precipitate at a temperature not exceeding 120°." *Br.* 1867.

Though the object of this formula is the same as that of the Br. Pharmacopœia of 1864, the proceeding is different. The point aimed at is to get an iron oxide containing one molecule of ferrous oxide and one of ferric oxide (FeO,Fe_2O_3 or Fe_3O_4, *Br.*). This was attained in the former process by converting a portion of ferrous sulphate by boiling with nitric acid into ferric sulphate, and then, having mixed this in solution with solution of ferrous sulphate, precipitating the two oxides conjointly with solution of soda. In the present formula the two sulphates are taken already formed; and the process consists essentially in precipitating, as before, their joint solutions by solution of soda, the proportion of the ferruginous salts being so adjusted as to yield a molecule each of the ferrous and ferric oxide. The solution of the salts of iron is directed to be added to that of the alkali; because, if the alkaline be added to the ferruginous solution, as there would be a great excess of the salt of iron, an insoluble basic sulphate would be precipitated, and might wholly or partially escape decomposition. (Redwood, *P. J. Tr.*, 1868, 464.) Such a compound oxide corresponds in composition with the native magnetic black oxide. The precipitate is washed to remove sodium sulphate, and the washings are known to be completed when barium chloride ceases to give a precipitate with them.

Properties. The artificial magnetic iron oxide is a brownish-black powder, without taste, and strongly magnetic. According to the former Br. Pharmacopœia, it consists of a 3–4 iron oxide, Fe_3O_4, with about 20 per cent. of water of hydration, and a portion of iron peroxide (sesquioxide). It dissolves without effervescence in hydrochloric acid diluted with half its bulk of water; and the solution gives a blue precipitate both with the potassium ferrocyanide and the potassium ferricyanide, showing the presence of ferrous and ferric oxide.

The former Br. Pharmacopœia gave the following tests. "When a small quantity is heated in a dry test-tube by the flame of a lamp, a deposit of moisture takes place on the cool part of the tube. Twenty grains dissolved in hydrochloric acid continue to give a blue precipitate with the red prussiate of potash (ferricyanide of potassium) until 83 grain-measures of the *volumetric solution of bichromate of potash* have been added." The former test simply indicates the presence of water in the oxide; the second the quantity of ferrous oxide present, which must be such as to require the indicated quantity of the bichromate for its conversion into ferric oxide. The dose is from five to twenty grains (0·33–1·3 Gm.).

Scales of iron (*ferri squamæ*) were formerly official with the Dublin College under the name of black oxide. They were prepared from the scales found at the blacksmith's anvil, by washing them with water, separating them from impurities by means of a magnet, and reducing them to a fine powder. They are of variable composition, being mixtures of the two oxides of iron with metallic iron.

FERRI SUCCINAS. *Ferric Succinate. Succinate of Iron.* The precipitate obtained by adding ferric chloride to a solution of a succinate is a basic salt $(C_4H_4O_4)_2Fe_2(OH)_2$. This is yellowish in color, becoming darker on standing. Ferric succinate has been introduced as a remedy for *jaundice* resulting from obstruction of the biliary duct; also as a chalybeate. Dose, five grains (0·32 Gm.).

FERRI TANNAS. *Tannate of Iron.* This salt is prepared by dissolving 44 parts of precipitated ferric subcarbonate, moderately dried, in a boiling solution of 9 parts of pure tannic acid, evaporating the solution at the temperature of 176°, in a porcelain vessel, until it becomes thick, pouring it out on a glass or porcelain plate, and drying it with a gentle heat. As thus obtained, ferric tannate is in flat pieces, of a crimson color, without taste, and insoluble in water. It is not a definite chemical compound. It acts as an astringent and tonic, and may be given in *chlorosis*, in the dose of from eight to thirty grains (0·518–1·94 Gm.), in the course of the

day, made into pills. *Ink* is an aqueous solution of the ferric gallo-tannate, and probably possesses similar medical properties. It is a popular application for *ringworm*.

FERRIC IODATE. *Iodate of Iron. Iodate of Sesquioxide of Iron.* $2Fe_2(IO_3)_6,Fe_2O_3,24H_2O$. This has been proposed as a substitute for the iodide by Prof. Cameron. (*Dublin Quarterly*, 1869, 354.) It is prepared by precipitating five fluidrachms of the stronger solution of iron perchloride in four fluidounces of water with a solution of one ounce of the potassium iodate in ten ounces of water. It is said to be nearly tasteless, and not to injure the teeth. Dose, from two to five grains (0·13–0·3 Gm.).

FERRIC SACCHARATE. *Saccharate de Fer, Saccharure d'Oxyde de Fer soluble*, Fr. *Eisenzucker, Lösliches Eisenoxyd*, G. The *Ferrum Oxydatum Saccharatum Solubile* of the German Pharmacopœia is of importance as an antidote to arsenic. (*Brit. and For. Med.-Chir. Rev.*, 1870, xlv. 558.) To twenty parts of a solution (43·5 per cent.) of the sesquichloride of iron are added 20 parts of simple syrup, and afterwards 40 parts of a solution of soda (30 per cent.). After twenty-four hours 300 parts of hot distilled water are added, and the precipitate washed by decantation and filtration; 90 parts of sugar are added, the whole dried in a water-bath, and enough sugar added to make the whole weigh 100 parts, containing the equivalent of 3 parts of metallic iron. E. Hoffmann has published a formula which he considers superior to the official. (See *Acidum Arsenosum*, PART I., and *A. J. P.*, xlvi. 559.)

FERRIPYRINE (*Ferropyrine*). It is stated by the manufacturers that this is a double compound of ferric chloride and antipyrin, with the formula $Fe_2Cl_6.3(C_{11}H_{12}N_2O)$. It is an orange-red powder, containing 12 per cent. of iron; it dissolves easily in 5 parts of cold water, forming a dark red solution. It has been used in *chlorosis* as a chalybeate; is strongly astringent, and affirmed to be often useful in chronic *diarrhœas*. Dose, from three to six grains (0·16–0·33 Gm.). In strong solution (1 to 5) it is said to be a powerful non-irritant styptic.

FERROSO-ALUMINIC SULPHATE. *Sulphate of Aluminum and Iron.* $Al_2Fe(SO_4)_4,24H_2O$. This double salt was brought forward by Sir James Murray, of Dublin, as an astringent, styptic, and vermifuge. His method of preparing it is not very clearly expressed, but it may be presumed to be formed by dissolving alumina and ferrous carbonate, both recently precipitated, in sulphuric acid, and duly evaporating the solution. Klauer states that is is produced in crystalline tufts when a solution of the component salts mixed with an excess of sulphuric acid is left to stand in a warm place. (*Watt's Dict.*, vol. v. 583.) Murray recommended it in *chronic dysentery*, *diarrhœa*, *fluor albus*, and the *colliquative sweats* and *diarrhœa* which attend hectic fever and consumption. Externally he found it a powerful styptic, useful as a gargle in *relaxation of the tonsils and uvula*, and in *salivation*, as an injection in *hemorrhages*, and as a wash for *foul and flabby ulcers*. Dose, from five to ten grains (0·324–0·648 Gm.), dissolved in some aromatic water.

FERROSOL. A double saccharate of ferrous oxide and sodium chloride. It contains 0·77 per cent. of iron, and is employed in anæmia and chlorosis.

FERROSTYPTIN. Dr. A. Eichengrün has introduced this antiseptic hæmostatic. It is in dark yellow crystals, soluble in water. Its solution is coagulated by heat. Dose, from five to eight grains (0·3–0·5 Gm.).

FERRUM PEPTONATUM. (German Unoff. Form.) Albumen, dry, 20 parts; hydrochloric acid (sp. gr. 1·124), 33 parts; pepsin (Germ. Ph. 1 to 100), 1 part; solution of oxychloride of iron (German Ph. "Dialyzed Iron"), 240 parts; water, a sufficient quantity. Dissolve the albumen in 2000 parts of water, add 30 parts of the hydrochloric acid, and the pepsin, and macerate the mixture during twelve hours at 40° C. Then neutralize it exactly with solution of soda, separate any precipitate which may have formed, and add the solution of oxychloride of iron previously mixed with 2000 parts of water. Now neutralize exactly with a dilute solution of soda, so as to precipitate the iron peptonate formed, and wash the latter with water by decantation until the washings are no longer rendered opalescent by silver nitrate. Then collect the precipitate upon a moistened straining cloth, allow it to drain, transfer it to a porcelain capsule, add 3 parts of hydrochloric acid, and warm gently until solution has taken place. Evaporate the liquid on a water- or steam-bath to a syrupy consistence, spread it on plates of glass, and dry it at a temperature of 50° C. (122° F.).

The product appears in the form of shining, brown, transparent laminæ or scales containing from 24 to 25 per cent. of metallic iron. It is slowly soluble in cold, more rapidly in warm water, to a clear, faintly acid liquid, which is not rendered turbid either by boiling or by alcohol. On slowly heating 10 C.c. of a solution (1 in 20) of *iron peptonate* with 2 C.c. of hydrochloric acid to boiling, the liquid at first becomes turbid, then separates flakes, which finally dissolve.

Liquor Ferri Peptonati. (German Unoff. Form.) *Peptonate of iron* prepared from 20 parts of albumen. Brandy, 200 parts; water, enough to make 2000 parts. Mix the *liquid iron peptonate* obtained from 20 parts of dry albumen (by the above formula), after solution has been effected by means of the hydrochloric acid, with the brandy and enough water to make 2000 parts.

FILMOGEN. *Liquor Adhesivus.* A vehicle for the application of medicinal substances to the skin. It is said to be a solution of pyroxylin in acetone containing a trace of fixed oil. It forms an elastic coating impervious to water.

FLAVORING EXTRACTS. Under this name, preparations from various aromatics are considerably used for culinary purposes. They are in the liquid form, and are generally alcoholic solutions of the sapid and odorous principles of substances having an agreeable flavor. For *Extract of Lemon*, *Orange*, *Cinnamon*, *Teaberry*, the official formulas may be used or modified to suit individual purposes. (See *Spiritus Limonis*, *Aurantii*, *Cinnamomi*, *Gaultheriæ*, in PART I. of this work.) *Extract of Almond* may be made by dissolving one fluidounce of oil of bitter almond, deprived of hydrocyanic acid, in one pint of alcohol; *Extract of Rose*, by dissolving half a fluidrachm of otto of rose in a pint of alcohol, macerating half an ounce of red rose leaves in the solution until the extract is of the desired depth of color, and filtering. For *Extracts of Vanilla* and *Ginger*, see *Tinctura Vanillæ* and *Tinctura Zingiberis* (PART I.). *Extracts of Celery Seed*, *Thyme*, *Sweet Marjoram*, *Sweet Basil*, *Summer Savory*, etc., may be made by bruising well two ounces of either, moistening with half a fluidounce

of diluted alcohol, packing in a percolator, and pouring on diluted alcohol until a pint is obtained. For formulas by Prof. Procter, see *A. J. P.*, 1856, 215, and 1866, 294.

FLINDERSIA MACULOSA. F. Muell. *Leopard-tree.* This is a tree of New South Wales, belonging to the Meliaceæ. During the summer it yields large masses of a clear amber-colored gum having a pleasant taste, which is eaten by the aborigines, and is used as a remedy for *diarrhœa*. *Leopard-tree Gum* occurs in pieces as large as pigeons' eggs; dissolves rapidly in cold water, and has been found by J. H. Maiden to contain eighty per cent. of arabin but no metarabin. (*P. J. Tr.*, vol. xxi., 1890.)

FLUORESCENCE. It has been proposed to use this property of various drugs to detect adulterations. (See *P. J. Tr.*, 1875; *A. J. P.*, 1875; *Phila. Med. Times*, 1875.)

FLUORESCIN. *Fluorescein.* $C_{20}H_{12}O_5$. It may be prepared by heating phthalic anhydride (5 parts) with resorcin (7 parts) to 200° C. Yellowish-red or dark red powder. Soluble in alcohol with yellow-red color and green fluorescence. With alkalies it exhibits a magnificent yellow-green fluorescence. This substance has the faculty of coloring abrasions of the cornea greenish, and has been used by some oculists for diagnostic purposes. The solution (10 grains to a fluidounce) in water containing sodium bicarbonate is not irritant.

FLUORIDES. *Hydrofluoric Acid* is a pungent, fuming, acid gas, very corrosive, attacking glass and porcelain and etching its surface. It is very soluble in water, the specific gravity of the solution rising to 1·25. The concentrated aqueous acid becomes weaker on boiling until, when boiling at 120° C., it attains a constant composition of from 36 to 38 per cent. of the anhydrous acid. Concentrated hydrofluoric acid is a powerful corrosive, having the peculiar property of hardening the skin or tissue with which it comes in contact and continuing its action underneath the hardened tissue, with an extraordinary amount and persistency of pain. For case, see *Bost. Med. and Surg. Journ.*, Jan. 1882; also *Brit. Med. Journ.*, vol. i., 1880. According to L. A. Waddell (*Indian Med. Gaz.*, 1833), the dilute 8 per cent. acid applied to the skin causes stinging sensation and pallor, followed by redness and desquamation. From 15 to 20 per cent. acid destroys the epithelium and produces severe burning and aching pain. The vapor of the acid is exceedingly irritant to the lungs, causing, even when very dilute, spasm of the glottis and other symptoms of irritation. According to Husemann, death has been produced by it. Waddell states that the alkaline fluorides are not pronounced irritants, and when taken internally in doses of from a grain to a grain and a half continuously, they reduce the force and the frequency of the pulse, at the same time depressing the temperature and increasing somewhat the flow of urine, but not distinctly affecting either the respiratory or the cutaneous functions. This accords with the physiological studies of Tappeiner, who found in animals the soda salt to powerfully depress blood-pressure by acting on the vaso-motor centres. Death, after profound collapse, was produced by centric failure of respiration. (*Arch. Exper. Path. Pharm.*, xxvii.) Dr. Waddell also affirms that there is an enormous decrease in the number of the red blood-corpuscles, which he believes, but does not prove, to be the result of a direct action upon the spleen. According to the experiments of Brandl and Tappeiner, when solid fluorides are given in minute quantities with the food, they become separated in the body, especially in the bones, where they form a crystalline combination. (*Zeitsch. f. Biologie*, x., 1892.) M. Maumené has asserted that when the alkaline fluorides are given to dogs for five months goitrous enlargement of the thyroid gland is developed. On the other hand, M. Rabuteau failed in a series of experiments to obtain any such results, and Dr. Woakes has employed the remedy in goitrous enlargement of the thyroid with asserted good results. The remedy has also been used by Dr. Da Costa in rheumatism, but in the clinical studies of Waddell the fluorides failed to do any good either in *rheumatism* or in *epilepsy*, although they did seem to accomplish something in *goitre*. Dose of the alkaline fluorides, one grain (0.065 Gm.).

The fluorides are stated to be active antiseptics, and as such to be used in distilleries. Under the name of *Fluorol*, Duclos has proposed the use of the *sodium fluoride* as being equally powerful and less toxic than the ordinary antiseptics. He reports that a 2 per cent. solution may be used upon the skin, mucous membranes, and wounds without irritation, and has used a half per cent. solution in diseases of the eye. In a very elaborate study, however, Bokorny found that the sodium fluoride is much less powerful as a germicide than is the *potassium fluoride*.

FORMALDEHYDE. HCHO + Ag. Formaldehyde was first prepared in 1868 by Hofmann by passing a mixture of air and methyl-alcohol vapor over heated platinum, and it is still practically obtained only from the oxidation of methyl alcohol. This is accomplished in "formaldehyde lamps," or on a larger scale in forms of apparatus such as that described by G. L. Taylor in *Amer. Journ. Pharm.*, 1898, 195. Formaldehyde is a gas condensing to a colorless mobile liquid at —21° C., and at a temperature slightly above this begins to change into a polymeric form known as paraformaldehyde. Hence the aqueous solution of formaldehyde probably contains paraformaldehyde. The commercial products are always aqueous solutions, the common strength being the 40 per cent. solution; a 50 per cent. solution is not permanent. Formaldehyde may be determined in aqueous solutions by treatment with excess of standard ammonia, which converts it into hexamethylene-amine. The excess of ammonia may then be titrated with standard acid. The mixture of the formaldehyde solution and ammonia should stand for at least twelve hours.

The discovery of Trillat in 1888 of the germicidal powers of formaldehyde has been abundantly confirmed. It probably ranks in power as a little inferior to corrosive sublimate, although it certainly is much stronger than carbolic acid. According to K. Walker, its 1 per cent. aqueous solution will destroy all pathogenetic spores within an hour. It is further claimed for it that it has the power of destroying the toxins of various diseases. (*Schmidt's Jahrb.*, Bd. cclii.) It has a very powerful action on various forms of organic matter; one part in four thousand completely decolorizes wine, precipitating extractive and coloring matters.

Upon the higher animals its action is comparatively feeble, excepting in that it is one of the most irritating substances known, producing when inhaled even in an extremely dilute form violent

irritation of the respiratory mucous membranes. According to Trillat, sixty-six centigrammes of it per kilo are not mortal to the guinea-pig, although the urine passed by the animal is not capable of putrefaction. Mosso and Paoletti found that fifty cubic centigrammes of it would produce in the dog, when given by the mouth, violent convulsions followed by death, which evidently were largely due to gastro-intestinal irritation, as the same amount injected hypodermically had much less effect

In practical medicine formaldehyde is useful only as a disinfectant, and is certainly one of the most effective of known substances when it can be used with propriety. Its gaseous nature especially fits it for employment in the disinfecting of rooms, for which purpose it is practically the only germicide that should be employed. Van Ermengen and Sugg have shown that books and other small objects containing the germs of diphtheria, tuberculosis, scarlet fever, small-pox, etc., were disinfected by 5 C.c. of formaldehyde in a litre of air. Horton got the same result from 1 C.c. of formalin to 300 C c. of air. It does not injure books, clothes, or furniture. Trillat, using methylic alcohol, found that it was possible to completely disinfect rooms and the furniture therein in six hours by the consumption of from four to six litres of the alcohol for each three hundred cubic metres of the room. According to Walter, washing the hands in a 3 per cent. solution, followed by alcohol, renders them completely aseptic, whilst the use of the 1 per cent. solution almost instantly deodorizes fæces. The 2 per cent. solution rapidly renders surgical instruments aseptic without injury. The 1 per cent. solution is strong enough for the cleansing of vessels.

Formaldehyde is much used for the preservation of human bodies; an injection of a 1 per cent. solution usually suffices, the body in a dry room rapidly hardening without decomposition. *Orth's solution* for microscopic purposes consists of one hundred parts of Müller's solution with ten parts of a 40 per cent. solution of formaldehyde. The constituents must be mixed at the time of use, as the solution rapidly undergoes decomposition.

Kaiserling's solution is highly recommended for the preservation of pathological specimens without change of color, provided the specimen in the solution be stored in the dark. The solution and method of using are as follows: formaldehyde (40 per cent.), 750 C.c.; distilled water, 1000 C.c.; potassium nitrate, 10 Gm.; potassium acetate, 30 Gm. The heart, kidneys, and brain are kept during a period of twenty-four hours in Kaiserling's fluid, though no harm is done if they remain from thirty-six to forty-eight hours. The specimen is then transferred to alcohol of 80 per cent., where it should remain for not longer than twelve hours. Subsequently it is to be put in alcohol of 95 per cent. for two hours, and finally preserved in a mixture of equal parts of water and glycerin, to which thirty parts of potassium acetate have been added.

As an antiseptic in the treatment of wounds formaldehyde appears to be of little value, on account of its extremely irritant nature, though in 2½ per cent solutions it has been used with alleged success in *psoriasis* and similar skin diseases, and has been recommended in *gonorrhœal vaginitis* and *urethritis*, 1 to 10,000.

Formaldehyde has been put upon the market by various manufacturers in various combinations with proprietary or trade names; probably all of these preparations are active, but certainly most of them are more expensive than is justified by the cost of manufacture.

For the disinfecting of apartments the formaldehyde may be made directly from methyl alcohol by means of the Trillat or other automatic lamps, such as are for sale. The difference in cost is shown by the fact that by the immediate formation of the gas with suitable apparatus the practitioner can make over thirty gallons of formaldehyde vapor for the cost of one pound of a commercial proprietary solution containing less than half a pint of the gas. In disinfecting a room, windows, doors, etc., should be tightly closed; closets, drawers, etc., thrown widely open; and all furniture should be so prepared as to be reached by the vapors as completely as possible. After the automatic apparatus has been started, the attendant, of course, must leave the apartment. The danger of fire with a proper apparatus is theoretical, and it can be entirely obviated by placing the lamp in a large metal pot or similar utensil. As the cost of the formaldehyde prepared in this way amounts to very little, at least twice as much methylic alcohol should be used as would be called for by Trillat's statement as given above.

The most important of the proprietary remedies containing formaldehyde are:

Formalin or *formol*, which is a 40 per cent. solution of formaldehyde in water. This percentage was probably selected by the manufacturers on account of the fact that the 50 per cent. solution undergoes decomposition upon standing.

Amyloform is a white, odorless powder, insoluble in ordinary menstruum, which is claimed to be a chemical union of formaldehyde with starch. It can be heated to 180° C. without decomposition, and therefore is readily sterilized. It is said to be non-poisonous, and has been used by Laiggard, Krabbel, and others as a dusting powder in the treatment of infected *ulcers* and wounds of all kinds. It is said to act more energetically in lessening secretion and as a disinfectant than iodoform.

Glutol (*Glutoform*) is made by the action of the solution of formaldehyde upon gelatin. It is a hard, clear, transparent mass, which may be pulverized.

Dextroform is a combination of formaldehyde and dextrin, soluble in water and glycerin; it affords, according to Bongartz, in from 10 to 20 per cent. solution, a very useful injection in gonorrhœa and other toxic diseases, or may be used for irrigation in half strength.

FORMANILIDUM. *Formanilid.* $C_6H_5NH.COH$. This substance, which is made by heating aniline with formic acid, or by distilling equal molecules of aniline and oxalic acid, occurs in long, colorless, prismatic needles, melting at 46° C., soluble in water, alcohol, glycerin, and oil. It has been used as an *antipyretic* and analgesic in the dose of from two to five grains (0·18–0·3 Gm.), but is said frequently to produce cyanosis and cardiac depression. Externally, mixed with equal parts of chalk, it has been used in diseases especially of the nasal pasages by Preisach, and in 2 per cent. solution by Meisel in *genito-urinary inflammations*. It is said to produce burning pain, lasting about a quarter of an hour, and followed by a mild analgesia continuing from eight to twelve hours.

FORMIC ACID. *Acidum Formicum.* $HCHO_2$. This acid, although deriving its name from having first been obtained from the ant (*Formica rufa*), is remarkable for the number of sources of its production. It can be made from some species of caterpillars, from the blood, urine, fluid of the spleen, and perspiration of human beings; it is found in the products of decomposition of a number of vegetable substances, in common oil of turpentine, as a decomposition product of tartaric acid contained in various fruits and in the juice of the stinging nettle. It may be produced artificially in many ways. The best method (Berthelot's) only will be given (*Ann. Ch. Phys.*, 3, 46, 477). Equal weights of oxalic acid and glycerin with 10 per cent. of water are gently heated, slightly over 100° C. (212° F.), in a capacious retort; carbonic acid gas and formic acid are produced, a little formic acid passing over into the distillate, the greater portion remaining in the retort, however, with the glycerin, from which it can be separated by adding an equal bulk of water, distilling slowly, and renewing the water in the retort as required, until the acid is all distilled off. Formic acid, in its most concentrated state, is a colorless liquid, sp. gr. 1·235 (medicinal acid, sp. gr. 1·063), fuming slightly upon exposure to the air, having a pungent sour taste, and, when applied to the soft skin, producing violent pain, and often ulceration. Diluted solutions are alone suitable for medicinal applications; equal parts of the strong acid and water have been used. *Spiritus Formicarum* of the German Pharmacopœia is made as follows: "Alcohol, *seventy parts:* Water, *twenty-six parts;* Formic Acid, *four parts*. Mix them. A clear, colorless liquid of an acid reaction. Specific gravity from 0·894 to 0·898." *P. G.*

The tests for *Acidum Formicum*, as given in the German Pharmacopœia, are as follows: "When mixed with solution of subacetate of lead, it throws down a white, crystalline precipitate. When the Acid is mixed with five parts of water, and saturated by yellow oxide of mercury, a clear solution results, which, on heating, evolves a gas and deposits a white precipitate, which rapidly turns gray and afterwards changes into shining, metallic, coalescing globules. 10 Gm. of the Acid should neutralize 54·35 C.c. of volumetric solution of soda, corresponding to 25 per cent. of absolute Formic Acid. When diluted with five parts of water, the Acid should not be affected by chloride of calcium nor by hydrosulphuric acid. On diluting 1 Gm. of the Acid with 5 Gm. of water and heating for ten minutes with 1 Gm. of yellow oxide of mercury, it should yield a neutral filtrate." *P. G.*

Formic acid, diluted with an equal measure of water, is sometimes used to excite the circulation in paralyzed limbs. It is rarely used internally; dose, five minims (0·33 C.c.).

Among the salts of formic acid, *ammonium formate* (NH_4CHO_2) has been used medicinally. Ramskill, at the Hospital for the Epileptic and Paralytic, in London, considers it useful in *chronic paralytic disease* with general torpor. It is contraindicated by any remaining active irritation or inflammation of the nervous centres or about them, which may have been the original seat of the lesion. Dose, five grains (0·33 Gm.); a larger quantity than this is apt to vomit. Gréhaut and Quinquaud have found that the formates are eliminated by the kidneys unchanged.

FORMIC ETHER. A paper on the physiological action of this substance may be found in the *Journ. de Pharm.*, Juin, 1872, 453.

FRANKENIA GRANDIFOLIA. Cham. and Schlecht. *Verba Reuma.* (Nat. ord. Frankeniaceæ.) This California herb, which contains about 6 per cent. of tannin, is employed as a topical remedy in *catarrhal affections*, especially of the nose and genito-urinary tract; also internally in doses of from ten to twenty minims (0·62–1·23 C.c.) of the fluid extract. For local application the fluid extract may be diluted with from two to five times its volume of water.

FRASERA. *Radix Fraserœ. Radix Colombo Americanæ. Racine de Colombo de Mariette (d'Amérique)*, Fr. *Fraserawurzel, Amerikanische Colombowurzel*, G. *American Columbo* (*Frasera Walteri*, Michaux; now *F. Carolinensis*, Walter) is a most elegant representative of the family of Gentianaceæ. From the root, which is triennial, long, spindle-shaped, horizontal, fleshy, and yellow, a strong, succulent, solid, smooth stem rises, from five to ten feet in height. The leaves are sessile, entire, glabrous, of a deep green color, and disposed in whorls, which commence at the root and ascend to the summit with successively diminishing intervals. The radical leaves, from five to twelve in number, are elliptical, obtuse, a foot or more in length by about four inches in breadth, and lie upon the ground in the form of a star. Those constituting the whorls are successively smaller as they ascend; the lowest oblong-lanceolate, the upper lanceolate and pointed. The flowers are numerous, large, yellowish white, and disposed in a beautiful terminal pyramidal panicle, from one to five feet long, the branches of which spring from the axils of the upper leaves. The segments of the calyx are lanceolate, acute, and somewhat shorter than those of the corolla. The filaments are inserted into the base of the corolla, between its segments, which they do not equal in length. The anthers are oblong and notched at the base. The ovary is oblong-ovate, compressed, and gradually tapers into the style, which ends in a bifid stigma. The fruit is an oval, acuminate, compressed, two-valved, one-celled, yellow capsule, containing from eight to twelve flat elliptical seeds.

The Frasera flourishes in the southern and western portions of the United States. It prefers rich woodlands and moist meadows. The period of flowering is from May to July; but the stems and flowers are produced only in the third year, the radical leaves being the only part of the plant which previously appears above ground. From this manner of growth, it is inferred that the roots, which were formerly included in the Secondary List U. S. P., should be collected in the autumn of the second or the spring of the third year. Before being dried, it should be cut into transverse slices.

As formerly in the market, Frasera was in pieces irregularly circular, an eighth of an inch or more in thickness, about an inch in diameter, somewhat shrunk in the middle, consisting of a central medullary matter and an exterior cortical portion, of a yellowish color on the cut surfaces, with a light reddish-brown epidermis. In appearance these pieces somewhat resembled columbo, but were easily distinguishable by the greater uniformity of their internal structure, the absence of concentric and radiating lines, and their purer yellow color without a greenish tinge. The root sliced longi-

tudinally, so as to imitate gentian, has been offered in the market as *American gentian*. The taste of Frasera is bitterish and sweetish. Water and diluted alcohol extract its virtues; and the tincture lets fall a precipitate upon the addition of water, but is not disturbed by tincture of galls. The hot infusion is not precipitated by solution of gelatin, and gives with iodine no signs of starch. These reactions afford additional means of distinguishing the root from columbo. Higinbothom, of Bermuda, found in it gum, pectin, glucose, wax, resin, fatty matter, yellow coloring matter, bitter extractive, and an acid which was probably peculiar. (*A. J. P.*, Jan. 1862, 23.) Mr. Frank W. Thomas has determined the entire absence of berberine. (*Ibid.*, July, 1868, 310.) G. W. Kennedy obtained *gentisic acid*, $C_{14}H_{10}O_5$, and *gentiopicrin*, $C_{20}H_{30}O_{12}$. (*Proc. A. P. A.*, 1873, 635.) Prof. Patch points out (*Ibid.*, 1881, 467) that the yellow coloring matter differs from gentisic acid in being less soluble in cold alcohol, more soluble in hot alcohol and in ether, in having a lower melting point (187° F.), and in behaving differently with nitric and sulphuric acids.

Frasera, *American Columbo*, is a feeble, simple bitter. Dose of powder, one drachm (3·8 Gm.); of infusion (℥i to Oi boiling water), two fluidounces (59 C.c.) a day. The fresh root is said to be emetic and cathartic.

FRAXINUS AMERICANA. L. *White Ash.* (Nat. ord. Oleaceæ.) The bark has been used in *dysmenorrhœa* by Charles P. Turner and others of Philadelphia. The wine may be made (Thomas S. Wiegand, *A. J. P.*, 1882) by macerating eight troyounces of powdered bark for three days in one pint of sherry wine, then transferring to a percolator, and pouring on sufficient menstruum to obtain two pints of percolate. The dose is a teaspoonful (3·69 C.c.).

FRAXINUS EXCELSIOR. L. *Frêne*, Fr. *Esche*, G. (Nat. ord Oleaceæ.) The bark of the *Common European Ash* is bitter and astringent, and at one time was employed in the treatment of intermittent fever. Keller believed that he had found in the bark a peculiar crystallizable principle which Buchner denominated *fraxinin;* but Rochleder and Schwartz proved that the crystals, formed along with the bitter substance obtained by the process of Keller, were nothing but mannite. (*Pharm. Centralblatt*, 1853, 312.) *Fraxin* or *paviin*, the crystallizable bitter principle discovered by Salm-Horstmar, is obtained by precipitating the decoction with lead acetate, washing the precipitate, decomposing it by hydrogen sulphide, and concentrating the solution, which deposits the fraxin in needle-shaped crystals. These are four-sided prisms, shining, white with a tinge of yellow, feebly bitter and astringent, inodorous, soluble with difficulty in cold but readily in hot water. They have the formula $C_{16}H_{18}O_{10}$. Fraxin is a glucoside, dilute acids decomposing it into *fraxetin*, $C_{10}H_8O_5$, and *glucose*, $C_6H_{12}O_6$. The concentrated warm solution has an acid reaction. When much diluted, it exhibits a clear blue fluorescence by daylight, especially if a trace of ammonia be present. Alkalies, alkaline earths, and the carbonates color it yellow; ferric chloride first colors it green, and then throws down a yellow precipitate. (*Chem. Centralblatt*, 1857, 452.) The leaves have long been used in *rheumatic affections*, and by the peasants of Auvergne as a specific in *gout*. M. Garot has shown that they contain 16 per cent. of *calcium malate*. (See *Journ. de Pharm.*, 3e sér., xxiv. 311; also 4e sér., xii. 60.) Dose, an ounce (31·1 Gm.), infused in half a pint (236 C.c.) of boiling water, three times a day. (See *Am. Journ. of Med. Sci.*, N. S., xxv. 492.)

FRENCH CHALK. A compact, unctuous, indurated talc, of a greenish color, glossy, somewhat translucent, soft and easily scratched, and leaving a silvery line on paper; used chiefly for marking cloth and for extracting grease-spots. (See *Talcum.*)

FRUIT ESSENCES, ARTIFICIAL. Several of the compound ethers have been found to possess the odor and flavor of certain fruits, a property which has led to their employment as flavoring materials for confectionery and desserts, under the name of fruit essences. The simple ethers present in these compounds, so far as they have become of commercial importance, are common ether or ethyl oxide, which should be called ethylic ether, and amyl oxide or amylic ether. Each of these ethers possesses basic properties, and has its alcohol; common or ethylic ether corresponding to common or ethylic alcohol, and amylic ether to amylic alcohol or fusel oil. These alcohols are hydrates of ethyl and amyl respectively. (See *Alcohol Amylicum*, and *Alcohol*, PART I.) Colored artificial essences are to be distinguished from the real by the following tests, founded upon the presence of aniline. Fuchsine dyes a woollen or silken thread a permanent rose color, the tint imparted by natural fruit-juice washes out (C. Puscher, *Journ de Pharm.*, 4e sér., xlv. 395); dilute mineral acids redden natural fruit essences, turning yellow those containing an aniline dye; half a volume of nitric acid *instantly* turns an artificial syrup yellow; potassium carbonate reddens artificial syrups, but has no effect on natural syrups; lead subacetate precipitates red with fuchsine, green with natural fruit. (M. Vandeyvere, *Journ. de Pharm.*, 4e sér., x. 457; Dr. Hagar, *A. J. P.*, xlv. 395.)

Ethyl Butyrate. Butyric Ether. $C_4H_7(C_2H_5)O_2$. This ether is readily prepared by mixing 100 parts of butyric acid with 100 of alcohol and 50 of concentrated sulphuric acid, and agitating the mixture for a short time. The ether forms a layer on the surface, and may be purified by washing it with water and subjecting it to the action of calcium chloride. Butyric ether is sparingly soluble in water, but very soluble in alcohol, and boils at 121° C. (249·8° F.). It is said to be much used to communicate a pineapple flavor to rum. Dissolved in 8 or 10 parts of alcohol, it forms the *pineapple essence*. From twenty to twenty-five drops of this essence, added to a pound of sugar containing a little citric acid, imparts to the mixture a strong taste of pineapple. *Butyric acid*, $C_4H_8O_2$, is formed during what is called the butyric fermentation, which usually consumes two or three months before it is completed, and which is preceded by the lactic fermentation. To prepare it, a solution of grape sugar is mixed with half its weight of chalk, and with about one-tenth of its weight of cheese to act as a ferment, and the whole is kept at the temperature of 32·2° C. (90° F.). The sugar is first transformed into a viscous substance, and afterwards into lactic acid, which is gradually converted into butyric acid, with the disengagement of hydrogen and carbonic acid. At the end of the fermentation the liquid contains principally a mixture of calcium butyrate and lactate, from which the butyric acid may be ob-

tained by precipitating the lime as a carbonate by sodium carbonate, and decomposing the resulting sodium butyrate with sulphuric acid. Butyric acid is a colorless liquid, of disagreeable odor and rancid taste. It dissolves in all proportions in water and alcohol, boils at 163° C. (325·4° F.); density, 0·973.

Ethyl Pelargonate. Pelargonic Ether. Œnanthic Ether. $C_2H_5,C_9H_{17}O_2$. A preliminary step in forming this ether is to prepare the *pelargonic acid.* This is most conveniently obtained, according to Dr. R. Wagner, by the action of nitric acid on oil of rue. Treat the oil with double its weight of very dilute nitric acid, and heat the mixture until it begins to boil. Two layers are formed in the liquid; the upper one being brownish, and the lower consisting of the products of the oxidation of the oil, with the excess of nitric acid. The lower layer, having been separated, is freed from the greater part of the nitric acid by evaporation in a zinc chloride bath, and then filtered. This filtrate is a solution of pelargonic acid, and may be converted into pelargonic ether by a prolonged digestion, at a gentle heat, with alcohol. The ether as thus prepared has the agreeable odor of quince, and when dissolved in alcohol in due proportion, forms the *quince essence.* (See *A. J. P.*, 1853, 320.) It is also obtained from wine lees, by adding sulphuric acid and water, and distilling in a current of steam. *Pure* pelargonic ether (œnanthic ether) is a colorless liquid, having a peculiar, vinous, stupefying odor, and a taste at first slight but afterwards acrid. Its sp. gr. is 0·8635 at 17·5° C., and its boiling point from 227° to 228° C. (440·6°–442·4° F.). It is insoluble in water, but dissolves readily in alcohol and ether. Pelargonic acid, first obtained from *Pelargonium roseum*, or rose geranium, belongs to the fatty acid series, and has the formula $C_9H_{18}O_2$. Delffs's analysis of œnanthic acid gives it the same composition, and he considers the two acids identical.

Amyl Acetate. Pentyl Acetate. $C_5H_{11},C_2H_3O_2$. This is prepared by distilling a mixture of one part of amylic alcohol (fusel oil), two of potassium acetate, and one of concentrated sulphuric acid. The distilled liquid is purified from free acid by washing with a weak alkaline solution, and from water by distillation from calcium chloride. It is a colorless, limpid liquid, lighter than water, boiling at 137° C. (278·6° F.), insoluble in water, but soluble in alcohol. It possesses the odor, in a remarkable degree, of the Jargonelle pear, and is manufactured on a large scale for flavoring syrups and confectionery. An alcoholic solution of this ether forms the *Jargonelle pear essence.* Fifteen parts of amylic ether acetate, with half a part of acetic ether, dissolved in 100 parts of alcohol, form what may be called the *bergamot pear essence*, which, when employed to flavor sugar acidulated with a little citric acid, imparts the odor of the bergamot pear, and a fruity, refreshing taste. Amyl acetate, mixed with butyric ether, forms another fruity compound, which recalls the odor of the banana, and forms, in alcoholic solution, the *banana essence.*

Amyl Valerianate. $C_5H_{11},C_5H_9O_2$. *Amyl Valerate. Apple Oil.* This is made by carefully mixing four parts of pure amylic alcohol (fusel oil) with four of sulphuric acid, and adding the mixture, when cold, to five parts of valerianic acid. The whole is warmed for a few minutes in a water-bath, and then mixed with a little water, which causes the ether to separate. Lastly, it is purified by washing it with water and a weak solution of sodium carbonate. It boils at 188° C. (370·4° F.), and has a sp. gr. of 0·879 at 0° C. An alcoholic solution of this ether, in the proportion of one part to six or eight of alcohol, forms a flavoring liquid under the name of *apple essence.* (See *Acidum Valerianicum.*)

Besides the essences here described, there are found in commerce the strawberry, raspberry, apricot, greengage, mulberry, and black currant essences, all of which may be viewed as various mixtures of the ethers of the ethyl and amyl series, modified by the addition of pure nitrous ether, tincture of orris, vanilla, volatile oils, etc., to bring about a resemblance to the fruit the odor and taste of which it is the object to imitate. In making these essences it is important that the materials should be pure, especially the fusel oil and alcohol. The alcohol used as a solvent should be rectified and deodorized.

Names of the Essences.	Chloroform.	Nitrous Ether.	Aldehyde.	Acetic Ether.	Formic Ether.	Butyric Ether.	Valerianic Ether.	Benzoic Ether.	Œnanthylic Ether.	Oil of Persicot.	Sebacic Ether.	Methyl-Salicylic Ether.	Amylic Alcohol.	Amyl-Acetic Ether.	Amyl-Butyric Ether.	Amyl-Valerianic Ether.	Oil of Lemon.	Oil of Orange.	Alcoholic Solutions saturated in the cold of: Tartaric Acid.	Oxalic Acid.	Succinic Acid.	Benzoic Acid.	Glycerin.

The fruit essences are extensively employed for flavoring ices, jellies, lozenges, and drops, and for making fruit syrups and effervescent beverages.

M. Kletzinsky prepared a table giving the ingredients, and their proportions, of a large number of fruit essences. This table has been carefully revised, as several important errors occurred in it. They are alcoholic solutions of different ethers, to which are sometimes added certain acid and natural essences. Glycerin is present in nearly all, being useful in blending and harmonizing the different flavors. The alcohol and other ingredients must be chemically pure. Each column represents the number of measures to be added to 100 measures of alcohol.

FUCHSINE. This compound, one of the older coal-tar colors, is either *rosaniline* hydrochloride or acetate, a complex body, the formula being $C_{20}H_{19}N_3 \cdot HCl$ or $C_{20}H_{19}N_3 \cdot C_2H_4O_2$. They form large crystals of a greenish lustre, which dissolve in water (the acetate more easily in cold water) with carmine-red color. They stain animal tissue directly violet-red, while vegetable fibre must first be mordanted. Dr Reiss (*Gaz. Heb. Méd. et Chir.*, 1888) recommends fuchsine in doses of from one-tenth to one-sixth of a grain (0·006–0·010 Gm.) as a specific in *acute* and *chronic Bright's disease*. Fuchsine and *Safranine*, $C_{21}H_{20}N_4$, are said to be largely employed in France for coloring wines red. In the experiments of Cazeneuve and Lépine (*Gaz Hebdom.*, Nov. 1885) fuchsine was found to be free from toxic properties, but safranine proved itself a violent poison, causing marked dyspnœa, acceleration of the heart's beat, violent diarrhœa and albuminuria, and death from respiratory paralysis.

FUCUS VESICULOSUS. L. *Sea-wrack. Bladder-wrack. Kelp-ware, Black-tang, Cutweed. Quercus Marina. Fucus (Varech) vésiculeux*, Fr. *Blasentang, Seetang, Meereiche*, G. (Nat. ord. Fucaceæ.) This sea-weed is perennial, with the frond or leaf flat, smooth and glossy, from one to four feet long, from half an inch to an inch and a half broad, furnished with a midrib throughout its length, dichotomous, entire upon the margin, and of a dark olive-green color. Small spherical vesicles, filled with a mixture of nitrogen and oxygen but no CO_2, are immersed in the frond near the midrib. The air in these vesicles has not the exact composition of the atmosphere; consisting, according to the analysis of M. Ernest Baudrimont, in one instance of 28·4 per cent. of oxygen and 71·6 of nitrogen, in another of 26·5 of the former and 73·5 of the latter. (*Journ de Pharm.*, 4e sér., ii. 446.) The fruit consists of roundish, compressed conceptacles, at the ends of the branches, filled with a clear tasteless mucus and containing oogonia and antheridia on distinct plants. The plant grows upon the shores of Europe and of this continent, attaching itself to the rocks by its expanded woody root. On the coasts of Scotland and France it is much used in the preparation of kelp. It is also employed as a manure, and is mixed with the fodder of cattle. It has a peculiar odor, and a nauseous saline taste. Several chemists have undertaken its analysis, but the results are not satisfactory. It contains much soda in saline combination, and iodine, according to Gaultier de Claubry, in the state of potassium iodide. M. Convoy has found in it 0·21 per cent. of iodine. (*P. J. Tr.*, x. 434.) These ingredients remain in its ashes, and in the charcoal resulting from its exposure to heat in close vessels. On the coast of France about a dozen species of sea-weed have been used in making kelp. According to M. Eugène Marchand, *Fucus vesiculosus* is one of those poorest in iodine, the different species of Laminaria containing far larger amounts of iodine than the Fucaceæ. (See *P. J. Tr.*, 1884, 1011.) *Laminaria digitata* (L.), Lam., and *L. stenophylla* contain ten times as much iodine as the Fuci, and are practically now the only kelps used in making iodine (See *P J Tr.*, 1884, 1026.)

The charcoal, which is sometimes called *Æthiops vegetabilis* or *vegetable ethiops*, has long had the reputation of a deobstruent, and been given in *goitre* and *scrofulous swellings*. The mucus contained in the vesicles was applied externally, with advantage, by Dr. Russell, as a resolvent in scrofulous tumors. M. Duchesne Duparc has obtained from it very good results in the treatment of morbid *obesity*. (*Journ. de Pharm.*, 1862, 65.) Dr. A. T. Carson affirms, however, that the *Fucus vesiculosus* is largely used in Ireland for fattening pigs; and it is doubtful whether its preparations are capable of reducing human obesity unless given in such doses as to interfere with digestion and injure the health. M. Dannecy prepares the extract from the plant, collected at the period of fructification and rapidly dried in the sun. The coarse powder he treats for three days, with four times its weight of alcohol of 86°, expresses at the end of this time, and subjects the residue twice successively to a similar treatment with alcohol of 54°. The tinctures are then mixed, the alcohol distilled off, and the remainder evaporated to the consistence of an extract. Of this extract, which is one-fifteenth of the plant, three pills, each containing twenty-five centigrammes (3·75 grains), may be taken daily in the beginning, and increased gradually to twenty-four pills. (*Journ. de Pharm.*, 1862, 434.) From the tincture a syrup may be prepared.

Other species of Fucus are in all probability possessed of similar properties. Many of them contain a gelatinous matter and a sweet principle analogous to mannite, and some are used as food in times of scarcity. Large quantities of a sea-weed, *agar-agar*, are gathered on the rocky coasts of the East India Islands, and sent to China, where it is valued for making jellies and as a size for stiffening silks. The varieties are classified by Fristedt as follows.

1. *Ceylon Agar-agar*, consisting chiefly of *Sphærococcus lichenoides*, Ag., the alga used by the *Hirundo esculenta* in the formation of its edible nest.

2. *Macassar Agar-agar*, coming from the straits between Borneo and Celebes, consisting of impure *Eucheuma spinosum*, incrusted with salt.

3. *Japanese Agar-agar*, known as Japanese isinglass (see p. 726), derived from several algæ, especially *Sphærococcus compressus*, Ag., *Gloiopeltis tenax*, J. Ag., *Gelidium corneum*, Lam., and *G. cartilagineum*, Gaill. It occurs in European commerce either in transparent pieces, two feet long and as thick as a straw, prepared in Singapore by putting the algæ named in hot water, or, more frequently, in yellowish-white masses, a foot long and upward of an inch in width. It is the latter kind that is suitable for the culture of bacteria, according to Koch's method. (*P. J. Tr.*, 1885, 188.)

Morin has investigated the *gelose* of Payen, contained in the agar-agar. When a solution of gelose is cooled, even that of 1 in 500 parts of water, a colorless, transparent, and stiff jelly is obtained, which, when heated with moderately strong nitric

acid, yields mucic and oxalic acids. It dissolves on heating with acidulated water without yielding a jelly on cooling.

Gelose leaves 3·88 per cent. of ashes, and when air-dried contains 22·85 per cent. of moisture. When dissolved there also separates out a flocculent mass amounting to 1·9 per cent. Alcohol precipitates gelose, but it cannot be obtained pure in this manner, as the precipitate contains some ash. (*Compt.-Rend.*, No. 90, 924–926.)

Under the name of *gelosine* a mucilaginous substance, extracted from a Japanese alga, has entered commerce in the form of dry, whitish leaves. Gelosine is soluble in alcohol and water, and is said when wet to gradually contract and expel water and the medicinal substances which it may contain. It has been proposed as a pharmaceutical basis for various preparations for local use. (See *Brit. Med. Journ.*, vol. ii. 1886.)

The *Ceylon moss* is a delicate fucus (*Gigartina lichenoides*) growing on the coast of Ceylon. It abounds in starch and vegetable jelly, and is used like carrageen or Irish moss. (*P. J. Tr.*, xiii. 355.) *F. Helminthocorton* (*Gigartina Helminthocorton* of Greville) has some reputation in Europe as an anthelmintic and febrifuge. It is an ingredient in the mixture of marine plants sold in Europe under the name of *Corsican moss* or *helminthocorton*. This is used in decoction, from four to six drachms to the pint; dose, a wineglassful three times a day.

Attention has been called by Sloan, of Ayr, Scotland, to the *Laminaria digitata*, L., Lamx., commonly called *sea-girdles* or *tangles*, of Scotland, as supplying an admirable material for bougies. The stem is from two to twelve feet long and an inch or more in breadth, is of great strength and tenacity, with the property of drying readily, and, in doing so, of shrinking much, and acquiring an elastic firmness, with a consistence, if the desiccation be arrested at the proper point, somewhat softer than horn. In this state the plant may be kept for years; and, if at any time exposed to moisture, will absorb it readily, and swell up to the original size. This last property renders it especially applicable for the formation of bougies or tents to be used in the *dilatation of strictures and sinuses*.

FULIGOKALI. This preparation, proposed by M. Deschamps, is formed by boiling for an hour 20 parts of caustic potassa and 100 of shining soot, in powder, in a sufficient quantity of water. The solution, when cold is diluted, filtered, and evaporated to dryness. Fuligokali is in the form of a black powder, or of scales, very soluble in water, and having an empyreumatic odor and mild alkaline taste. It is used in the same affections as *anthrakokali*. The dose is two or three grains, repeated several times a day. An ointment, containing from sixteen to thirty-two grains to the ounce of lard, was found by Dr. Gibert, of Paris, to be detersive, resolvent, and gently stimulant. (*A. J. P.*, xiv. 284.)

FUMARIA OFFICINALIS. L. *Fumitory. Fumeterre*, Fr. *Erdrauch, Feldraute*, G. (Nat. ord. Papaveraceæ.) A small annual European plant, naturalized in this country, growing in cultivated grounds, and flowering from May to August. It was formerly considerably employed as a medicine, and is still used in Europe. The leaves are the official part. They are inodorous, have a bitter, saline taste, and are very succulent, yielding by expression a juice which has the sensible and medicinal properties of the plant. An extract, prepared by evaporating the expressed juice or a decoction of the leaves, throws out upon its surface a copious saline efflorescence. *Fumaric acid*, $C_4H_4O_4$, was early identified as present, and its isomerism with *maleic acid*, the acid obtained from malic acid by heat, was established later. The alkaloid *fumarine*, which was first observed by Peschier, has been believed by some chemists to be identical with corydaline, but according to Reichwald (*P. J. Tr.*, xix. 990) its formula, $C_{21}H_{19}N.O_4$, is different from that of corydaline, from which it further differs in striking immediately an intense violet with concentrated sulphuric acid and an intense golden color with strong nitric acid. It occurs in colorless, tasteless crystals, freely soluble in chloroform, less so in benzole, still less so in alcohol and ether, sparingly soluble in water. He obtained it by treating the pulp of the leaves with concentrated acetic acid, with the aid of heat, filtering, evaporating the liquid, treating the extract with boiling alcohol, filtering the alcoholic solution, and, finally, decolorizing, and evaporating so that crystals might form. The acetate thus procured was decomposed by the alkalies, and yielded the fumarine. (See Adermann, *A. J. P.*, 1890, 396.) Fumitory has been considered gently tonic, alterative, and, in large doses, laxative and diuretic. M. Hannon has found fumarine, in the dose of about one-third or one-fourth of a grain, to be moderately excitant; in that of three grains, to be at first irritant and afterwards sedative. (*Ann. de Thérap.*, 1854, 78.) Both in ancient and modern times fumitory has been esteemed a valuable remedy in visceral obstructions, particularly those of the liver, in scorbutic affections, and in various troublesome eruptive diseases. Cullen gave two ounces of the expressed juice twice a day. Others have prescribed it in much larger quantities. The leaves, either fresh or dried, may be used in decoction or extract, in almost indefinite dose. The inspissated juice has also been employed.

FUSTIC. A yellow dye-wood, obtained from *Morus tinctoria*, L. (*Broussonetia tinctoria*, H. B. K.; *Maclura tinctoria*, D. Don (now *Chlorophora tinctoria* (L.), Gaudich), a tree of the nat. ord. Moraceæ, growing in the West Indies and South America. It is not used in medicine or pharmacy. According to Bancroft, two different woods bear in England the name of fustic, one the product of the tree just mentioned, distinguished as *old fustic*, probably from the greater magnitude of the billets in which it is imported; the other derived from the *Rhus Cotinus* or *Venice sumach*, and called *young fustic*, or sometimes *Hungarian fustic*. The wood of *M. tinctoria*, L., owes its coloring properties to two principles, which have been isolated by R. Wagner; one denominated *morin*, or *morindon*, $C_{15}H_{10}O_5$, and the other *moritannic acid*, $C_{13}H_8O_8$, from its resemblance to tannin. The former, when distilled with zinc-dust, yields methyl-anthracene, whence the conclusion has been drawn that it is a trioxymethylanthraquinone, $C_{15}H_7O_2(OH)_3$. (See *Chem. Gaz.*, ix. 1, 21, and 241.) From the fustic of *Rhus Cotinus*, L. (nat. ord. Anacardiaceæ), or Hungarian fustic, M. Chevreul extracted a yellow coloring matter, in small crystalline needles when pure, which he called *fisetin*. J. Schmidt (*Ber. der Chem. Ges.*, 19, 1734–1749) has made a thorough study of fisetin, and prepared a number of derivatives of it. He states that it occurs in the wood as a tannic acid compound of the glucoside of fisetin, which he calls *fustin*. This latter body crystallizes

from hot water in fine silvery needles, easily soluble in alcohol and dilute alkalies, sparingly in ether. It melts at from 218°–219° C. with decomposition. By warming with dilute H_2SO_4 it is split up into fisetin and a glucose (probably isodulcite). The *fisetin* has the formula $C_{15}H_{10}O_6$, and as it contains four hydroxyl groups, it is probably a tetroxymethylanthraquinone, $C_{15}H_6(OH)_4$. It is obtained by recrystallization from dilute alcohol or acetic acid; it forms fine yellow needles or yellow prisms ($+ 6H_2O$). It is very slightly soluble in hot water, easily soluble in alcohol and acetic ether, sparingly in ether and benzene.

GALANGAL. *Galanga. China Root. India Root. Rhizoma Galangæ*, P. G. *Galanga*, Fr. *Galgant*, G. Two varieties are described by authors, the *galanga major* and *galanga minor*, or *large* and *small galangal*. They are probably the roots of different plants. The large galangal is derived from *Maranta Galanga* of Linn. (*Alpinia Galanga* of Willd.). According to H. F. Hance, of Canton, the smaller galangal is the product of a distinct but closely allied plant, *Alpinia officinarum*, Hance. (*A. J. P.*, xliii. 408.) Both forms are brought from the East Indies. The *larger variety* is cylindrical, three or four inches long, as thick as the thumb or thicker, often forked, reddish brown externally, slightly striated longitudinally, marked with whitish circular rings, orange-brown internally, rather hard and fibrous, difficultly pulverizable, of an agreeable aromatic odor, and a pungent, hot, spicy, permanent taste. The *small galangal* resembles the preceding in shape, but is smaller, not exceeding the little finger in thickness, of a darker color, and of a stronger taste and smell. According to Morin, galangal contains a volatile oil, an acrid resin, extractive, gum, bassorin, and lignin. A. Vogel, Jr., found also starch and fixed oil. (*Pharm Centralblatt*, 1844, 158.) R. Brandes discovered a peculiar crystallizable substance called *kæmpferid*. (*Annal. der Pharm.*, xxxii. 311; see also *Arch. d. Pharm.*, 1882, 161.) The active principles are the volatile oil and acrid resin. Thresh has described (*A. J. P.*, 1884, 553) an active pungent principle, which he has named *galangol*. Galangal is a stimulant aromatic. It was known to the ancient Greeks and Arabians, and formerly entered into numerous compounds. (*A. J P.*, xliii.) Dose, from fifteen to thirty grains (0·972–1·94 Gm.) in substance, and twice as much in infusion.

GALEGA OFFICINALIS. L. *Goat's Rue. Herbarutæ Caprariæ. Galega, Rue de Chèvre*, Fr. *Geisraute*, G. A perennial leguminous herb, growing in the south of Europe, and sometimes cultivated in gardens. It is without smell unless bruised, when it emits a disagreeable odor. Its taste is unpleasantly bitter and somewhat rough, and when chewed it stains the saliva yellowish brown. In former times it was much employed in *malignant fevers*, the *plague*, the *bites of serpents*, *worms*, etc. In 1873 Gillet-Damitte, in a communication to the French Academy, stated that this plant when fed to cows would increase the secretion of milk from 35 to 50 per cent.; since which time Cerisoli, Goubeaux, Masson d Audry, Dr. Millbank, and Dr. Carron de la Carrière have affirmed that goat's rue is a powerful galactagogue. The best preparation appears to be an aqueous extract prepared from the fresh plant. This almost black extract has a pronounced odor, and may be given in doses of from seven and a half to fifteen grains (0·49–0·97 Gm.), from three to five times a day. The roots of the indigenous *Galega Virginiana*, L. (*Tephrosia Virginiana*, Pers., now *Cracca Virginiana*, L.), are said to be diaphoretic and powerfully anthelmintic. They are given in decoction.

GALIUM APARINE. L. *Cleavers. Goose-grass. Grateron, Rièble*, Fr. *Klebkraut*, G. This is an annual, succulent, rubiaceous plant, common to Europe and the United States, growing in cultivated grounds, and along fences and hedges. It is inodorous, and has a bitterish, herbaceous, somewhat acrid taste. Analyzed by Schwartz, it was found, besides chlorophyll, starch, and other principles common to all plants, to contain three distinct acids,—viz., a variety of tannic acid, which he names *galitannic acid*, citric acid, and a peculiar acid, previously discovered by Schwartz and Rochleder, and named *rubichloric acid*, $C_{14}H_8O_9$. (*P. J. Tr.*, xii. 190.) The expressed juice is said to be aperient, diuretic, and antiscorbutic, and has been used in *dropsy*, *congestion of the spleen*, *scrofula*, *scorbutic eruptions*, and *lepra*. Three ounces (88·7 C.c.) may be taken twice a day. Dr. Orwin (*Therap. Gaz.*, vol. i. 767) commends it highly in *psoriasis*.

GALIUM VERUM. L. *Yellow Ladies' Bedstraw. Cheese Rennet. Caille-lait jaune*, Fr. *Megerkraut, Liebfrauenstroh*, G. The flowers of this European Galium (nat. ord. Rubiaceæ) are yellow, have a peculiar agreeable odor, and have been used as an antispasmodic. The herb is inodorous, but has an astringent, acidulous, bitterish taste. The bruised plant is sometimes used to color cheese yellow, being introduced into the milk before coagulation. It is also used for dyeing yellow. The roots of this and of most other species dye red; and the plant, eaten by animals, colors the bones like madder. Schwartz found the same principles in it as in *G. Aparine*. It was formerly highly esteemed as a remedy in *epilepsy* and *hysteria*, and was applied externally in *cutaneous eruptions*, in the form either of the recently expressed juice or of a decoction from the fresh plant. Of the American species, *G. tinctorium*, L., is closely allied in properties to *G. verum*. It is said to be useful in *cutaneous diseases;* and the root is employed by the Indians for staining their feathers and other ornaments red. *G. triflorum* (Michx.) contains coumarin, as pointed out by L. von Cotzhausen. (*A. J. P.*, 1876, 405.)

GALLACETOPHENONE. (*Alizarine Yellow.* C.) $C_6H_2\left\{\begin{matrix}(OH)_3\\CH_3CO\end{matrix}\right.$. This is a derivative of pyrogallol, containing an acetyl group replacing a H atom of the benzene nucleus. Forms a pale yellow powder, crystallizing from hot water, in which, as well as in alcohol and ether, it is readily soluble. It is also soluble in glycerin in all proportions. This substance has been proposed as a substitute for pyrogallic acid in the local treatment of *psoriasis*, it being claimed that it does not stain, and is not so poisonous as the acid.

GALLINOL. *Gallanol. Gallanilid.* $C_6H_2\left\{\begin{matrix}CO.NH.C_6H_5\\(OH)_3\end{matrix}\right. + 2H_2O$. This anilid of gallic acid is formed by boiling tannin with aniline, and was brought forward by Cazeneuve and Rollet as a local remedy to replace chrysarobin in the treatment of skin diseases. (*Comptes-Rend. de l'Acad. des Sci.*, 1893.) It occurs in colorless crystals melting at 205° C., of a bitter taste, soluble in hot water, ether, and alcohol, insoluble in benzene and chloroform. It has been especially commended by Gonon, Bayet,

Max Joseph, and others, not only in *psoriasis*, but also in chronic *eczema*, to be used in a 10 per cent. solution or ointment, or sometimes in very advanced cases as high as 20 per cent.; it is affirmed never to produce irritation. The removal of the hair is not necessary, provided the skin be thoroughly cleansed with alkaline soap solutions.

GALLOBROMOL. *Dibromgallic Acid.* $C_6Br_2(OH)_3COOH$. A colorless or pale grayish-red powder, composed of fine needles melting at 205° C.; soluble with difficulty in cold water, easily soluble in hot water, alcohol, and ether, and having a strong acid reaction and a slightly bitter taste. It has been used by Lépine in *neurasthenia* and *epilepsy* to replace bromide of potassium, but it would seem to be a somewhat dangerous remedy, as in Lépine's experiments a dog weighing 11 kilogrammes was killed in two hours by 11 Gm., death having been preceded by slowing of the heart's action, depression of respiration, rise of temperature, convulsions, and methæmoglobinuria. According to Stein, it is to dogs more poisonous than the sodium bromide, less than the potassium bromide. In the dog small doses produce a primary moderate rise of the blood-pressure, followed by fall of pressure, with cardiac arythmia. Dose (Lépine): as a sleeping potion, forty-five grains; in epilepsy, from thirty to forty-five grains a day. (See *Centralb. f. Gesammte Therap.*, xiii., 1895.)

GALLOLS. E. Kromayer (*Monatshefte für Prakt. Dermatologie*, vii.) has tested as remedies for diseases of the skin a number of chemical combinations of pyrogallol, chrysarobin, and resorcin, with various acids. Of these a few give promise of therapeutic usefulness.

Lenigallol, pyrogallol triacetate, is described as a white insoluble powder, slowly soluble on warming with aqueous solutions of alkalies, with decomposition.

Eugallol, pyrogallol monoacetate, is a very thick, syrupy, transparent, dark yellow mass, readily soluble in water.

These substances are stated not to be affected by contact with healthy skin, but to be slowly decomposed by the diseased skin with the liberation of pyrogallol. Strong ointments of lenigallol are to be employed in *psoriasis*, 1 to 2 parts of lenigallol to 200 parts of zinc paste in *eczemas*. Even the most acute eczemas, as well as those with impetiginous crusty exudations, are reached by the ointment.

Eugallol produces great local excitement, and is only to be employed in the most obstinate cases of *psoriasis*. Under such circumstances, however, the direct local application as a paint, daily or every other day, produces a marked inflammation, under which the most stubborn patches are said to disappear. Dusting the painted parts with zinc oxide before drying makes the action more vigorous. The value of eugallol has been strongly confirmed by Paul Gruneberg (*Dermat. Zeit.*, vi., 1899), who uses in *lupus* a zinc paste with from 11 to 12 per cent. of eugallol continuously applied after free curetting, and in *psoriasis* a 33½ per cent. acetone solution followed by zinc oxide dressing.

Saligallol, pyrogallol disalicylate, is a resinous solid, useful in the preparation of skin varnishes, soluble in six parts of acetone or fifteen parts of chloroform. The deposit is very adhesive, but has no curative effect. It is useful as a means of applying eugallol.

Eurobin is *chrysarobin triacetate*. It is insoluble in water, but is readily soluble in chloroform, acetic acid, acetone, or ether. It acts like chrysarobin on the skin, but is more powerful. Kromayer commends it applied as a paint, according to the following formula. Saligallol, 5 to 10 parts; eurobin, 1 to 20 parts; acetone, to make 100 parts.

Lenirobin, chrysarobin tetra-acetate, is less irritant than chrysarobin, and has the especial advantage of not staining the linen.

Euresol, resorcin monoacetate, is a viscid, rather fragrant, transparent, yellow mass, which is commended by Kromayer in *acne rosacea, seborrhœa*, and other conditions for which resorcin is commonly used.

GARDENIA GRANDIFLORA. (Lour.?) (Nat. ord. Rubiaceæ.) A Chinese tree, the fruit of which is employed in dyeing the yellow robes of the mandarins; and, according to Lorenz Mayer, contains *crocin*, which in powder is of a bright red color, and soluble in water and alcohol. According to the latest researches of Kayser (*Ber. der Chem. Ges.*, 1884, 2228), its formula is $C_{44}H_{70}O_{28}$. When heated with dilute hydrochloric or sulphuric acid, it is decomposed into *crocetin*, $C_{34}H_{46}O_9$, and a dextro-rotatory sugar called *crocose*. Alkalies bring about the same decomposition almost instantly. Concentrated sulphuric acid dissolves both the crocin and crocetin with deep blue color. The fruit of another species, *G. campanulata*, Roxb., growing in the forests of Chittagong, in India, is said to be used by the natives as a cathartic and anthelmintic. (Lindley, *Flor. Med.*, 434.)

GARRYA FREMONTII. Torr. *California Fever Bush Skunk Bush.* The leaves of this California bush (nat. ord. Cornaceæ) have an intensely bitter taste, and are said to be largely used by Californians as a tonic and antiperiodic. Mr. D. W. Ross (*A. J. P.*, 1877) states that he has found in them a new alkaloid, *Garryine*. The dose of the fluid extract of the leaves is from ten to thirty minims (0·62–1·85 C.c.).

GAULTHERIA. *Wintergreen. Boxberry. Checkerberry. Feuilles de Gaulthérie* (*de Paloninier*), *Thé du Canada, Thé de Terreneuve*, Fr. *Canadischer Thee, Bergthee*, G. *Gaultheria procumbens*, L. (nat. ord. Ericaceæ), is a small, indigenous, shrubby, evergreen plant, with a long, creeping, horizontal stem, which sends up at intervals one or two erect, slender, round, reddish branches. These are naked below, leafy at top, and usually less than a span in height. The *leaves*, which were formerly official in the U. S. Pharmacopœia, are short-petiolate, obovate or roundish oval, about an inch and a half (4 centimetres) long, and three-quarters of an inch (2 centimetres) or more broad, acute, revolute at the edges with a few mucronate serratures, coriaceous, shining, bright green above, paler beneath, of unequal size, and supported irregularly on short red petioles. The flowers, of which not more than from three to five are usually on each stem, stand upon curved, drooping, axillary peduncles. The calyx is white, five-toothed, and furnished at its base with two concave cordate bracts, described by some as an outer calyx. The corolla is white, ovate, or urceolate, contracted at the mouth, and divided at the border into five small acute segments. The stamens have curved, plumose filaments, and oblong orange-colored anthers opening on the outside. The ovary, which rests upon a ring having ten teeth alternating with the ten stamens, is roundish,

depressed, and surmounted by an erect filiform style, ending in an obtuse stigma. The fruit is a small, five-celled, many-seeded capsule, with a fleshy covering, formed by the enlarged calyx, and presenting the appearance of a bright scarlet berry.

The plant extends from Canada to Georgia, growing in large beds in mountainous tracts, or in dry barrens and sandy plains, beneath the shade of shrubs and trees, particularly of other evergreens, as the Kalmiæ and Rhododendra. It is abundant in the pine-barrens of New Jersey. In different parts of the country it is variously called *partridge-berry*, *deer-berry*, *tea-berry*, *wintergreen*, and *mountain-tea*. The flowers appear from May to September, and the fruit ripens at corresponding periods. To the very pecular aromatic odor and taste which belong to the whole plant the leaves add a marked astringency. The aromatic and medicinal properties of wintergreen reside exclusively in an official volatile oil. (See *Oleum Gaultheriæ*, PART I.)

GELANTHUM. *Gelanth.* Gelanth is a combination of equal weights of tragacanth and gelatin, prepared by Unna as a basis for various pastes for the skin. It is stated to be superior to the older pastes in drying more quickly and leaving a smoother coating upon the skin, as well as in holding more uniformly and in tighter suspense the drug used with it, and finally in not spoiling readily. It is made by allowing tragacanth to soften with twenty times its mass of water for four weeks, then warming the mass to fluidity with steam and pressing it through a mill. In the mean while gelatin has been softened in the water and then for some time exposed to a high pressure of steam in Unna's boiler, which exposure lessens its capability of gelatinization. The mixture of the two masses is allowed for two days to soften in the steam, then passed through a mill and mixed with 5 per cent. of glycerin, a little rose-water, and 2 per cent. of thymol. The finished gelanth contains about 2½ per cent. (each) of dry gelatin and tragacanth. In using it as a basis, fatty matters must first be emulsified and insoluble substances rubbed up with water to a soft paste before they are mixed with the gelanth.

GENISTA TINCTORIA. L. *Dyers' Broom. Dyers' Weed. Green Weed. Wood-Waxen. Genet des Teinturiers*, Fr. *Färberginster*, G. (Nat. ord. Leguminosæ.) A low shrub, growing wild in Europe, and sometimes cultivated in this country in gardens. The flowering tops of the plant are employed to dye yellow, whence its name was derived. Both these and the seeds have been used in medicine. They are said to be purgative and even emetic, especially the seeds, which were formerly given as a cathartic in the dose of a drachm and a half. By some authors they are said to be diuretic, and to be useful in *dropsy*.

GERANIUM ROBERTIANUM. L. *Herb Robert. Herbe à Robert*, Fr. *Ruprechtskraut*, G. (Nat. ord. Geraniaceæ.) This species of geranium grows wild both in Europe and the United States, and Pursh states that the American plant is destitute of the heavy smell by which the European is so well known, though the two agree in all other respects. The herb has a disagreeable, bitterish, astringent taste, and imparts its virtues to boiling water. It has been used internally in *intermittent fever*, *consumption*, *hemorrhage*, *nephritic complaints*, *jaundice*, etc., has been employed as a gargle in *affections of the throat*, and has been applied externally as a resolvent to *swollen breasts* and other *tumors*.

GEUM. *Water Avens. Radix Caryophyllatæ Aquaticæ. Radix Benedictæ Sylvestris. Racine de Benoîte aquatique* (*de Benoîte des Ruisseaux*), Fr. *Sumpfnelkenwurzel*, *Wasser-Benedikten-Wurzel*, G. Several species belonging to this genus have been medicinally employed, but three or four are deserving of particular notice,—*Geum rivale*, L., which once had a place in the U. S. Secondary List, *G. urbanum*, L., formerly recognized by the Dublin College, *G. virginianum*, L., an indigenous species, the root of which has been recommended in *dysentery* by Dr. W. A. Gibson, of St. Louis (*Med. Record*, 1868), and *G. album*, Gmel. (now *G. canadense*, Jacq.), recommended by W. A. Spurgeon in *gastric irritation* and *headache*. (*A. J. P.*, 1883.)

Geum urbanum, or *avens*, is a native of Europe, where it grows wild in shady places. The root, which is the part used, consists of a short, oblong body, from a quarter to half an inch in thickness, externally brown, internally white towards the circumference and reddish at the centre, and furnished with numerous long descending fibres. When quite dry it is nearly inodorous, but in the recent state has a smell like that of cloves, whence it is sometimes called *radix caryophyllatæ*. The taste is bitterish and astringent. It imparts its virtues to water and alcohol, which it tinges red. Buchner obtained a yellow, amorphous, neutral, bitter-tasting mass, which he calls *geum-bitter*. Distilled with water it yields 0·04 per cent. of a thick, greenish-yellow volatile oil, and gives a pleasant clove-like flavor to the liquid. It contains, besides, according to Trommsdorff, tannic acid, which is abundant, a tasteless resin, gum, bassorin, and lignin. It has been much used in Europe as a tonic and astringent, in chronic and passive *hemorrhages*, *chronic dysentery* and *diarrhœa*, *leucorrhœa*, *intermittent fever*, etc. The dose is from thirty grains to a drachm of the powder three or four times a day, or an equivalent quantity in decoction.

Geum rivale. L. *Water avens* has a perennial, horizontal, jointed, scaly, tapering root, about six inches long, of a reddish-brown color externally, white internally, and furnished with numerous descending yellowish fibres. One or more stems rise from the same root, which also sends up numerous leaves. The stems are about a foot and a half high, simple, erect, pubescent, and of a purplish color. The radical leaves are interruptedly pinnate, with large terminal leaflets, and long, hairy footstalks; those of the stem are petiolate, and divided into three serrate, pointed segments. The flowers are few, solitary, nodding, yellowish purple, and supported on axillary and terminal peduncles. The color of the stems and flowers gave rise to the name of *purple avens*, sometimes applied to the plant. The calyx is inferior, with ten lanceolate, pointed segments, of which the five alternate are smaller than the others. The petals are five, and as long as the calyx. The achenes are oval, with plumose awns, minutely uncinate, and nearly naked at the summit. This species of Geum is common to Europe and the United States, though the plant of this country has smaller flowers, with petals more rounded on the top, and leaves more deeply incised than the European. It delights in wet, boggy meadows, and extends from Canada into New England, New York, and Pennsylvania. Its flowers appear in June and July. The dried root is hard,

brittle, easily pulverized, reddish or purplish, without smell, and of an astringent, bitterish taste. Boiling water extracts its virtues.

Water avens is tonic and powerfully astringent. It may be used with advantage in *chronic* or *passive hemorrhages*, *leucorrhœa*, and *diarrhœa*, and is said to be beneficially employed in the Eastern States as a popular remedy in the debility of *phthisis pulmonalis* and in *simple dyspepsia*. In Europe it is sometimes substituted for the root of *common avens*, or *Geum urbanum*, but is less esteemed. The dose of the powdered root is from a scruple to a drachm, to be repeated three times a day. Dose of the decoction (ounce to the pint), one or two fluidounces (29·7–59·00 C.c.). A weak decoction is sometimes used by invalids in New England as a substitute for tea and coffee.

GILLENIA. *Bowman's Root. Racine de Gillénie*, Fr. *Gillenienwurzel*, G. Under this name the U. S. P. formerly included in its Secondary List the roots of *G. trifoliata*, Moench., and *G. stipulacea*, Nutt. (Nat. ord. Rosaceæ.)

Gillenia trifoliata, Moench. (*Porteranthus trifoliatus* (L.), Britt.), is an herbaceous plant with a perennial root, consisting of many long, slender, brown branches, proceeding from a thick, tuber-like head. The stems, several of which usually rise from the same root, are two or three feet high, erect, slender, smooth, flexuose, branched, and commonly of a reddish color. The leaves are ternate, with very short petioles, and small linear-lanceolate stipules. The leaflets are ovate-lanceolate, sharply serrate, and acuminate. The flowers grow in a loose terminal nodding panicle, with long peduncles. The calyx is tubular campanulate, ventricose, and terminates in five-pointed segments. The corolla is composed of five linear-lanceolate, recurved petals, the two upper separated from the three lower, white, with a reddish tinge on their border, and of three times the length of the calyx. The stamens are twenty, the filaments short, the anthers small and yellow. Each flower is succeeded by five capsules, connate at the base, oblong, acuminate, gibbous without, acute within, two-valved, one-celled, opening inward, and containing each one or two oblong seeds. This plant grows throughout the United States, east of the Alleghany ridge, and, in Pennsylvania, may also be found abundantly west of these mountains. It frequents light soils, in shady and moist situations, and flowers in June and July. The root should be gathered in September. (See *A. J. P.*, 1898, 501.)

G. stipulacea, Nutt. (*Porteranthus stipulatus* (Muhl.), Britt.), is herbaceous and perennial, though much taller and more bushy than the preceding. The stems are brownish and branched. The upper leaves are ternate, lanceolate, serrate; the lower more deeply incised, becoming towards the root pinnatifid, and of a reddish-brown color at the margin. The stipules are ovate, acuminate, deeply serrate, resembling leaves, and marking the species at the first glance. The flowers are smaller than those of *G. trifoliata*, Moench., and grow on long slender peduncles in a lax corymb. In the valley of the Mississippi this plant occupies the place of *G. trifoliata*, Moench., which is not found beyond the Muskingum. It grows as far north as the State of New York, extends through Ohio, Indiana, Illinois, and Missouri, and probably into the States south of the Ohio, as it has been found in West Virginia. Its root is precisely similar to that of the Eastern species, and is reputed to possess the same properties.

The dried root of Gillenia (*Indian Physic*, *American Ipecacuanha*) is not thicker than a quill, wrinkled longitudinally with occasional transverse fissures, and, in the thicker pieces, presenting in some places an irregular, undulated, somewhat knotty appearance, arising from indentations on one side corresponding with prominences on the other. It is externally of a light brown color, and consists of a thick, somewhat reddish, brittle cortical portion, with an interior slender, tougher, whitish, ligneous cord. For microscopic characters, see G. L. Curry. (*Amer. Pract. and News*, May, 1892.) The bark, which is easily separable, has a bitter, not disagreeable taste; the wood is nearly insipid and comparatively inert, and should be rejected. The powder is of a light brownish color, and possesses a feeble odor, which is scarcely perceptible in the root. The bitterness is extracted by boiling water, which acquires the red color of wine. The root yields its bitterness also to alcohol. By various experimenters it has been shown to contain gum, starch, gallo-tannic acid, fatty matter, wax, resin, coloring matter, albumen, and lignin, besides salts. (*A. J. P.*, xxvi. 490.) *Gillenin* of Mr. W. B. Stanhope is a whitish substance, very bitter, slightly odorous, permanent in the air, soluble in water, alcohol, ether, and the dilute acids, and neutral to test-paper. Nitric acid rendered it blood-red, chromic acid green. Tannic acid produced no effect. It gave white precipitates with potassa, lead subacetate, and tartar emetic. Half a grain of it produced nausea and retching. (*A. J. P.*, xxviii. 202.) G. L. Curry (*A. J. P.*, 1892, 513) has found two glucosides: the first, *gillein*, obtained from the ethereal extract, formed white feathery crystals, was colored red by sulphuric acid, yellow by nitric acid, and deepened the color of chromic acid; the second, *gilléenin*, obtained from the aqueous infusion, was amorphous, of yellowish color, of faint taste at first but becoming very bitter, and giving no color reactions with the acids.

Gillenia is a mild and efficient emetic, and, like most substances belonging to the same class, occasionally acts upon the bowels. In very small doses it has been thought to be tonic, and has been used as a substitute for ipecacuanha, which it is said to resemble in its mode of operation. It was employed by the Indians, and became known as an emetic to the colonists at an early period. Linnæus was aware of its reputed virtues. Dose of the powdered root, from twenty to thirty grains (1·29–1·95 Gm.).

GLASS OF ANTIMONY. *Vitrum Antimonii.* This is prepared from antimony tersulphide by a partial roasting and subsequent fusion. Glass of antimony is in thin irregular pieces, which have a vitreous fracture, and a metallic steel-gray lustre. When well prepared, it is transparent, and, upon being held between the eye and the light, appears of a rich orange-red or garnet color; but if of inferior quality it is black and opaque. It is hard and brittle, and rings when struck with a hard substance. It is insoluble in water, but soluble in acids and cream of tartar, with the exception of a few red flocculi. Its essential constituents are the teroxide and tersulphide, united in variable proportions. Sometimes *glass of lead* is sold for glass of antimony, a fraud readily detected by the difference between the two substances in specific gravity; glass of lead having a density of nearly seven, while that

of glass of antimony is not quite five. Glass of antimony is an active antimonial; but, owing to its variable composition and unequal operation, it is very seldom used When the levigated powder is mixed with one-eighth of its weight of melted yellow wax, and the mixture roasted over a slow fire, with constant stirring, until it ceases to exhale vapors, a coal-like pulverizable mass is formed, the *cerated glass of antimony* of the old Edinburgh Pharmacopœia.

GLECOMA HEDERACEA. L. *Herba Hederæ Terrestris. Lierre terrestre*, Fr. *Gundermann, Gundelrebe*, G. *Nepeta Glechoma*, Benth. *Ground-ivy.* A small perennial, labiate herb, indigenous in Europe and the United States, and growing in shady, grassy places, as in orchards and along fences and hedges. The herb was formerly official, and still enjoys some credit as a domestic remedy. It has a peculiar disagreeable odor, and a bitterish, somewhat aromatic taste, and imparts its properties to boiling water. It is very prone to have galls developed on it, and to be infested with certain fungi. (*Journ. de Pharm.*, 1875, 127.) It is said to be gently stimulant and tonic, diuretic, and aperient; useful in chronic pulmonary and urinary catarrhs. From a half-drachm to a drachm (1·9–3·8 Gm.) was usually given in infusion as a dose.

GLEDITSCHINE. In 1878 (*Phila. Med. Times*) *Gleditschia triacanthos*, L., and *G. ferox*, Desf. (nat. ord. Leguminosæ), were chemically studied by B. F. Lautenbach, who abstracted from them an alkaloid, which he found to produce in the frog stupor and loss of reflex activity, due to an action upon the spinal cord. To this alkaloid Dr. Lautenbach gave the name of *gleditschine.* In 1887 (*Med. Rec.*, July 31, 1887) Mr. Goodman and Drs. Seward and Claiborne brought before the profession, as a local anæsthetic, an alkaloid under the name of *stenocarpine.* Subsequently Dr. Caiborne (*Med. Rec.*, Oct. 1, 1887) announced that the tree from which this alkaloid is obtained is the *Gleditschia triacanthos*, and suggested the name of gleditschine for it. The alleged alkaloid was placed upon the market in solution, and was largely used as a local anæsthetic and mydriatic by oculists. In October or November, 1888, however, Mr. F. H. Thompson, of Detroit (*Med. Age*) and Prof. T. G. Novy (*Pharm. Rundschau*) and Dr. John Marshall, of the University of Pennsylvania (*Phila. Med. News*), published analyses of this solution, showing that it contained 6 per cent. of cocaine, besides some atropine or other mydriatic alkaloid: gleditschine was a fraud. (See also *A. J. P.*, 1887, 589.)

GLOBULARIA ALYPUM. Delile. (Now *G. arabica*, Jaub. and Spach.) *Wild Senna of Europe.* (Nat. ord. Selagineæ.) This is a small shrub, growing on the European shores of the Mediterranean, the leaves of which have been occasionally used as a cathartic since the middle ages. Dose, according to Planchon, one ounce in decoction. Heckel and Schlagdenhauffen obtained from the leaves *globularin*, an amorphous glucoside which splits by treatment with mineral acids into glucose and *globularetin. Globularia vulgaris*, L., was found to contain the same substances. (*Journ. Pharm. Chim* , 1883, 361.)

GLORIOSA SUPERBA. L. The roots, stalk, and leaves of this climbing liliaceous plant are said to be an acrid narcotic poison, and not infrequently used for suicidal purposes in India. C. J. H. Warden found in them two resins, and a very poisonous bitter principle, *superbine.* (*P. J. Tr.*, xi. 496.)

GLUE. An impure form of gelatin, obtained from various animal substances by boiling them in water, straining the solution, and evaporating it till upon cooling it assumes the consistence of jelly. The soft mass which results is then divided into thin slices, which are dried in the open air. Glue, when of good quality, is hard and brittle, of a color varying from light yellow to brown, and equally transparent throughout. It softens and swells very much in cold water, without dissolving; but is readily dissolved by hot water. It is soluble in a large proportion of glycerin, and with heat forms with it in smaller proportion a jelly. (Maisch, *A. J. P.*, xlii. 518.) It is employed chiefly for cementing wood.

An elastic and imputrescible preparation of glue may be made by dissolving glue in water by means of a water-bath, concentrating the solution, then adding a weight of glycerin nearly equal to that of the glue employed, thoroughly mixing, evaporating the residue of the water, and finally pouring into moulds, or on a marble slab. It is especially applicable to the preparation of artificial anatomical specimens. (*Journ. de Pharm.*, 1857, 28.) The various *hectograph* compositions introduced within recent years for copying purposes are similar mixtures. One of the best copying masses is made by dissolving one part of glue or gelatin in a mixture of two parts of water and four parts of glycerin, with a few drops of carbolic acid, heating, straining, and adding three parts of sifted whiting or terra alba. (See *N. R.*, 1879, 338, 364.) A good *liquid glue* may be made by rubbing up in two pints of rain-water, with the heat of a water-bath, sixteen ounces of the best white glue and four ounces of dry white lead, until thoroughly mixed, then adding four fluidounces of alcohol, and continuing the heat and the agitation for a few minutes. The mixture is to be poured into bottles while still hot. A *liquid glue* may also be prepared by mixing in a stoppered bottle 38 parts of glue, properly divided, and 100 parts of acetic acid of commerce, the latter of which dissolves the glue. On exposure the acid evaporates, leaving the glue unchanged. (*Journ de Pharm.*, 3e sér., xlvi. 35.) It is stated that an excellent *liquid glue* may be made by dissolving glue in sweet spirit of nitre. M. Knaff prepares *strong liquid glue* by covering three parts of good glue, in small pieces, with eight parts of water, and, after it has stood for some hours, adding half a part of hydrochloric acid and three-fourths of a part of zinc sulphate, and exposing the whole for ten or twelve hours to a heat from 81·1° to 87·2° C. (178°–189° F.). This does not gelatinize, and keeps well. (*A. J P.*, 1868, 330.) For a *water-proof glue* add potassium bichromate to the solution of glue just before using, one part to fifty. (*A. J. P.*, xliii. 420.) *Chromatized gelatin*, obtained by the addition of one part of potassium bichromate to five parts of a solution (5 or 10 per cent.) of gelatin, forms an excellent cement for glass. The surfaces to be united, after being smeared with the cement, are placed upon each other and exposed to the sun. After a few hours the adhesion is perfect and almost invisible, and boiling water itself has no action on the cement. (*Lond. Lancet*, Nov. 11, 1876.) For other formulas for liquid glue, see *A. J. P.*, xliii. 421.

GLUTOID CAPSULES. Gelatin capsules which have been hardened by exposure to formaldehyde are recommended by Sahli in three grades, the weak capsule capable of withstanding the action of the gastric juices for from one and a half to seven

hours, the strong for twelve hours. They appear to have great therapeutic value for the purpose of conveying intestinal antiseptics, medicinal substances which are destroyed by the peptic secretions, and irritating drugs through the stomach into the intestines. They have been used by Sahli (*Deutsch. Arch. f. Klin. Med.*, lxi.) for diagnostic purposes. By their means he asserts that he is able to determine the condition of the pancreatic secretion and the closure of the pancreatic duct, the varieties of jaundice, etc.

GNAPHALIUM MARGARITACEUM. L. (Now *Anaphalis margaritacea* (L.), Benth. and Hook.) *Cudweed. Life-everlasting. Pied de Chat, Immortelle*, Fr. *Katzenpfötchen Immerschön*, G. (Nat ord. Compositæ.) An indigenous herbaceous perennial, growing in fields and woods, and flowering in August. The herb of this species and of *G. polycephalum*, Michx. (now *G. obtusifolium*, L.), or *sweet-scented life-everlasting*, is sometimes used in the form of tea in intestinal and pulmonary *catarrhs*, and, externally, in the way of fomentation, in *bruises;* but it probably possesses little medical virtue Schoepf says that it is anodyne. In Europe different species of Gnaphalium are occasionally employed for similar purposes. (See *Antennaria margaritacea.*)

GOLD. The chief preparations of gold which have been employed in medicine are metallic gold in a finely divided state, the oxide (teroxide, incorrectly called auric acid), the chloride (terchloride), the iodide, the double gold and sodium chloride, now official, the ammonium chloraurate (a compound of gold terchloride and ammonium chloride), and the gold cyanide (tercyanide). *Gold in powder* may be obtained by rubbing up gold-leaf with ten or twelve times its weight of potassium sulphate until brilliant particles are no longer visible, and then dissolving away the sulphate with boiling water. The *oxide* may be procured by treating the nitrohydrochloric solution of gold with an excess of magnesia, and washing the precipitate, first with water, and afterwards with dilute nitric acid. This process being tedious, M. L. Figuier prefers to obtain the oxide by precipitating the cold solution of gold chloride, rendered strongly alkaline by caustic potassa, with a solution of barium chloride. The precipitate, consisting of barium aurate, is then treated with dilute nitric acid, which dissolves the barium and leaves the gold oxide pure. Ten parts of gold, thus treated, produced 11·75 parts of oxide; while the same quantity of gold by the magnesia process yielded only 9 parts. (*Journ. de Pharm.*, Dec. 1847.) The *chloride* is obtained by dissolving pure gold in three times its weight of nitrohydrochloric acid, with the aid of moderate heat. The solution is evaporated by a gentle heat nearly to dryness, being at the same time stirred with a glass rod. It is in the form of a crystalline mass of a deep red color. Its solution has a fine yellow tint. Being deliquescent, it requires to be kept in ground-stoppered bottles. (See *Auri et Sodii Chloridum.*) The *iodide* may be made by precipitating a solution of gold terchloride by one of potassium iodide, and washing the precipitate with alcohol to remove the excess of iodine. It is of a greenish-yellow color, and, when heated in a porcelain crucible, is resolved into iodine vapors and a residue of pure gold. The *ammonium chloraurate* is formed by dissolving one part of the gold terchloride and two parts of ammonium chloride in distilled water, assisted by a few drops of nitrohydrochloric acid, and evaporating the solution to dryness by a gentle heat. The *cyanide* is best obtained, according to M. Oscar Figuier, as follows. Prepare the gold chloride as neutral as possible by repeated solutions and crystallizations; and to the solution of this salt add, very cautiously, avoiding any excess, a solution of *pure* potassium cyanide, so long as any precipitate falls. (See *Potassii Cyanidum.*) The precipitate, consisting of gold cyanide, is to be washed with pure water, and dried in the dark. Gold in powder, and the oxide, chloride, iodide, sodio-chloride, and cyanide, are official in the French Codex.

The preparations of gold are decidedly poisonous, though in different degrees. The chloride is most virulent, and, according to Dr. Chrestien, is even more active than corrosive sublimate. In an overdose, it produces pain, inflammation, and even ulceration of the stomach and bowels, and otherwise acts as a corrosive poison. It is said that these preparations, in moderate doses, produce increased fulness and frequency of the pulse, and augment the urine and insensible perspiration, without interfering with the appetite or the regular action of the bowels; but, if the dose be pushed too far, general irritation is apt to be produced, inflammation seizes upon some organ, according to the predisposition of the individual, and fever is developed.

Gold in powder, *the oxide*, *chloride*, and *iodide* are not as much used as the soluble gold and sodium chloride. The oxide may be given in the form of pill, containing the tenth of a grain (0·006 Gm.), in *scrofula* and *lymphatic swellings*, beginning with one pill daily, and afterwards gradually increasing to seven or eight in twenty-four hours. The chloride has been used with advantage as a caustic in *lupus*, and in *syphilitic tubercles* and *ulcers*, by M. Chavannes. The iodide may be given in the same cases with the other preparations. The dose is from the fifteenth to the tenth of a grain (0·004–0·006 Gm.).

In 1889 Goubert asserted before the French Academy that gold bromide, administered in a weak solution, is more efficacious and durable in its action in *epilepsy* than are any of the other bromides, and is also better tolerated. This statement led Shtcherbak to study the effect of the gold bromide upon the motor area of the cerebral cortex, according to the method of Albertoni. He found that in the dose of from one-half to three grains per kilogramme of weight it so depressed the cortical motor centres that even the strongest electric stimulation failed to bring about any epileptic seizures. It is further asserted that the gold bromide never causes in man general depression, languor, emaciation, or other pronounced symptoms of bromism. The amount of bromine in the bromide, 55 per cent. by weight, would seem too small to make it probable that the bromine is the active ingredient of the salt. The dose of the bromide for the adult is from eight to twelve milligrammes; for children, three to six milligrammes. As a substitute for this preparation, E. Merck has proposed *gold and sodium bromide* (*Aurum-Kalium bromatum*, $AuBr_3.KBr+2H_2O$), which has been tested by I. Jankura and Prof. Laufenauer (*Pest. Med. Chirurg. Presse*, 1892), and found to be a valuable anti-epileptic. It may be used hypodermically, by dissolving 2 parts of the salt in 100 parts of distilled water, and injecting of this half a cubic centimetre (8 minims), and increasing the dose to two cubic centimetres (32 minims).

Ammonium chloraurate has been recommended by Bouchardat in *amenorrhœa* and *dysmenorrhœa* in debilitated subjects, in the dose of about the tenth of a grain (0·006 Gm.). A grain may be dissolved in five teaspoonfuls of alcohol and five of water, and a teaspoonful given morning and evening, mixed with sweetened water.

Gold cyanide is employed, like the gold and sodium chloride, mixed with inert powders by friction, and in the form of pill. The fifteenth of a grain (0·004 Gm.) may be rubbed into the gums daily for fifteen days, next, the fourteenth of a grain for fourteen days, and so on, increasing until the dose amounts to the ninth or eighth of a grain (0·0075 or 0·008 Gm.). The dose for internal exhibition is the eighteenth of a grain, gradually increased to the eighth (0·0038–0·008 Gm.). Gold cyanide has been found useful in the treatment of *syphilis* and *scrofula* by M. Pourché, and is said to be less exciting than the double chloride.

The different medicinal compounds of gold should not be prepared in pill, powder, or otherwise until they are wanted for use, as they are liable to undergo decomposition when kept. They should be carefully secluded from the light.

GRASS-TREE GUM. An Australian product, said to be obtained by exudation from different species of Xanthorrhœa, especially *X. hastilis.* R. Br. (Nat. ord. Juncaceæ.) It is of a resinous character, usually as found in the markets in the state of small fragments or coarse powder, resulting from the breaking up of the larger brittle masses in which it first occurs. It is of a deep reddish-yellow color in mass, but greenish yellow in powder. It does not dissolve in the mouth when chewed, nor adhere to the teeth, but has a slightly astringent and aromatic flavor. It melts with heat, and at a higher temperature takes fire in the air, burning with a smoky flame, and emitting a fragrant odor not unlike that of balsam of Tolu. It yields picric acid largely under the action of nitric acid. The natives and early settlers employed it as a medicine in *diarrhœa.* It is said to be used extensively, instead of shellac, in cabinet work, but to be distinctly inferior. For much interesting information concerning it and other resinous products of the genus Xanthorrhœa, see paper by J. H. Maiden, *P. J. Tr.*, vol. xxi., 1891. It is obtainable in inexhaustible quantities, as the plants producing it are abundant throughout almost the whole of Australia. (*A. J. P.*, 1866, 465.) Three hundred tons of the resin of *X. hastilis* have been exported in one year, and at one time the price rose to £65 per ton for the best quality, but for ordinary quality it is from £7 to £10. (*A. J. P.*, 1885, 405.) (See article *Xanthorrhœa Resins*, p. 1833.)

GRATIOLA VIRGINIANA. L. *Gratiola Officinalis.* Michx. *Hedge-hyssop. Gratiole*, Fr. *Gnadenkraut, Gottesgnadenkraut*, G. (Nat. ord. Scrophulariaceæ.) This is a perennial herb, indigenous in the south of Europe, in meadows and other moist grounds. The whole herb is used. It is nearly inodorous, but has a bitter nauseous taste. Both water and alcohol extract its active properties. F. G. Walz found in it the following constituents: 1, *gratiolin;* 2, *gratiosolin;* 3, *gratioloic acid;* 4, *gratiola fat;* and 5, a brown resin, The gratiolin is decomposed on prolonged boiling with dilute H_2SO_4 into *gratioletin, gratiolaretin*, and sugar; the gratiosolin is similarly decomposed by dilute acids or alkalies into *gratiosoletin* and sugar; the gratioloic acid is obtained in the form of pearly white scales of a fatty odor. Hedge-hyssop is a drastic cathartic and emetic, possessing also diuretic properties, and has been used in Europe for the relief of *dropsy, jaundice, worms, chronic hepatic affections*, and *scrofula.* The dose of the powdered herb is from fifteen to thirty grains (0·972–1·94 Gm.); of the infusion (half an ounce to the pint of boiling water), half a fluidounce.

GROUND-NUTS. *Pea Nuts. Goober Nuts.* The fruit of *Arachis hypogœa*, L., a leguminous, annual plant, indigenous probably in Africa and South America, and abundantly cultivated in our Southern States, China, etc. Thirty thousand tons are said to be produced annually in Senegal, whilst the export from Madras in a single year amounts to one hundred thousand tons of the nuts (known there as *pistaches*), besides large quantities of the oil; the present annual product of Virginia and North Carolina is over two million bushels. A remarkable property of the plant is that its fruit ripens under the surface of the ground, into which the pods penetrate in the progress of their growth. The seeds constitute the well-known ground-nuts of our markets, which consist of a dry, brittle envelope and a yellowish-white kernel. When roasted, ground-nuts constitute for many a very agreeable article of food, and in the South are said to be much used as a substitute for coffee. They contain about 45 per cent. of a fixed oil. It is obtained by expression; the nuts being ground into a paste, and moderately heated before being submitted to pressure. The oil consists of the glycerides of four different fatty acids. The chief of these is *oleic acid*, $C_{18}H_{34}O_2$, with which are associated *hypogœic acid*, $C_{16}H_{30}O_2$, *arachidic acid*, $C_{20}H_{40}O_2$, and *lignoceric acid*, $C_{24}H_{48}O_2$. As described by Mr. Jonas Winter, the oil has a bright yellow color, the characteristic odor of the fruit, and a mild not unpleasant taste, although a bleached ground-nut oil now manufactured in France and used for adulterating lard oil and olive oil is nearly colorless and almost free from taste. It is soluble in all proportions in ether, chloroform, and benzin, but insoluble in alcohol. Its sp. gr. is 0·918 at 15·5° C. (60° F.). At 3·3° C. (38° F.) it thickens, solidifies at about —5° C. (+23° F.), and at 326·6° C. (620° F.) is decomposed, giving out spontaneously inflammable vapors. Mr. Winter made experiments to ascertain how far it might be employed with advantage in pharmacy, and found that it answered well in the preparation of cerates and ointments, but would not serve as a substitute for olive oil in the preparation of lead plaster. (See *Proc. A. P. A.*, 1897, 179, for later views on the subject.) It is a non-drying oil, and will not therefore answer for painting; but it is enormously used for adulteration and for various purposes in the arts, as for lubricating machinery, and in the manufacture of woollen cloths; in lamps it burns with a bright light. It saponifies slowly, but yields an excellent firm, white, and odorless soap.

GUACO. This name is given in Central and South America and the West Indies to various plants belonging to the genera Mikania and Aristolochia; but it is to the different species of the former genus that the name properly belongs, especially to *Mikania Guaco*, Humb. and Bonpl. (now *M. amara*, Willd.). The plants are closely allied to the Eupatoria. *Mikania houstonis*, Willd., *M. gonoclada*, D. C. (all of the nat. ord. Compositæ);

Aristolochia fragrantissima, Ruiz, *A. grandiflora*, Sw., *A. pentandra*, Jacq. (all of the nat ord. Aristolochiaceæ); *Comocladia integrifolia*, Jacq. (nat ord. Anacardiaceæ), are also said to furnish guaco. *Mikania Guaco*, Humb. and Bonpl., is described as having twining stems, with round, sulcate, and hairy branches; ovate, subacuminate, remotely dentate leaves, somewhat narrowed at the base, rough above and hairy beneath; and flowers in opposite axillary corymbs. The plant is a native of intertropical America, and has been introduced into the West India Islands from the continent. The leaves are the part used. The result of a long and close investigation into the natural history of guaco by the distinguished Guibourt is, that the *Mikania Guaco*, instead of possessing, as has been asserted, a strong, penetrating, and nauseous odor, is in fact inodorous, and destitute of all active properties; and that the strongly aromatic plants which have been employed under the name of guaco all belong to the genus Aristolochia, especially *A. cymbifera*, Mart. and Zucc., growing in Brazil, after this *A. maxima* (De Cand. ?), and in less degree *A. geminiflora*, H. B. K. (now *A. maxima*, Jacq.). (*Journ. de Pharm.*, 1867, 99.)

Although the guacos of South America seem to be entirely distinct drugs, they appear to be indiscriminately used by the natives for the cure of the *bites of poisonous serpents*, as was first made known by Mutis, and afterwards confirmed by Humboldt and Bonpland. The medicine is also used in South America as a febrifuge and anthelmintic, and has been considered anti-syphilitic. A few years ago it attracted on the continent of Europe considerable attention on account of its alleged power in *epidemic cholera* and *chronic diarrhœa*. The *Aristolochia cymbifera*, Mart. and Zucc., has been the subject of a careful study by Dr. L. Butte. The root of this plant as it occurs in commerce is cylindrical, from three to four centimetres in diameter, much broken up into long rootlets, yellowish, with a strong odor, especially in the bark. The plant itself is a vine, growing in great abundance in the province of Tabasco in Mexico. Dr. Butte was not able to find in it either an alkaloid or a glucoside, but he found a blackish resin which may be the active principle of the plant, though this does not seem probable, since Dr. Butte found the alcoholic extract much less active than the aqueous extract, which would hardly be the case if the resin were really the active principle. In the physiological experiments made with the aqueous extract it was found that in the guinea-pig and rabbit massive doses produced cries and excitement, followed after a time by sleep, with muscular relaxation and diarrhœa. In the dog vomiting and diarrhœa were very marked. The muscular relaxation was probably centric, as the motor nerves and muscles were in a condition of activity. An apparent loss of function in the sensory nerve-trunks Dr. Butte believed to be due not to paralysis of the nerve-fibres, but of the centres of sensation. Although the muscle was not completely paralyzed, careful experimentation showed that its contractility was less than the norm after death from the poisoning. Death was produced by an arrest of the respiration. The heart continued to beat both in the reptile and the mammal after the cessation of respiration; nevertheless there was depression of the arterial pressure, apparently due to the action of the drug upon the heart. After death marked signs of gastro-intestinal irritation were found, the medicine having been given by the mouth. During life the urine was albuminous, and at the autopsy the kidneys were found congested. The temperature gradually rose during the poisoning, and less glucose than normal was found in the blood. Dr. Butte believes that guaco has valuable therapeutic principles in the treatment of skin affections, especially *eczema* and *pruriginous maladies*, in which he used it both locally and internally. He gives the dose of the aqueous extract of guaco as three grains, three times a day. In the external application the following formula was used. Guaco (bruised), 30 parts; sodium bicarbonate, 5 parts; water, 1000 parts; boil for a quarter of an hour, allow to macerate one hour, decant, and use the liquid as a lotion. (*Annales de la Policlin. de Paris*, Sept. 1890.) Guaco is said to be largely used in South America as an anti-rheumatic, and Dr. E. W. Pritchard (*P. J. Tr.*, 1861) affirms that in the *gouty paroxysms* it is especially effective given in the dose of a drachm of the tincture every four hours, and applied locally.

GUAIACOL. *Methyl Pyrocatechin. Monomethyl Ether.* $C_6H_4\begin{cases}OH\\OCH_3\end{cases}$. This is obtained by the fractional distillation of beechwood creosote, of which it constitutes from 60 to 90 per cent. It may also be made synthetically from pyrocatechin and methyl sulphuric acid, and is obtained in the dry distillation of guaiac resin. The chemically pure guaiacol is a liquid with an agreeable odor, sp. gr. at 15° C. of 1·33, and boiling at from 206°–207° C. (402·8°–404·6° F.). Among the derivatives of guaiacol that have been used in medicine recently are *benzosol* (*benzoyl-guaiacol*, $C_6H_4\begin{cases}OCOC_6H_5\\OCH_3\end{cases}$), *guaiacol salol* (*salicyl-guaiacol*, $C_6H_4\begin{cases}OC_7H_5O_2\\OCH_3\end{cases}$), *styracol* (*cinnamyl-guaiacol*, $C_6H_4\begin{cases}OC_9H_7O\\OCH_3\end{cases}$), *guaiacol carbonate*, $CO(OC_6H_4OCH_3)_2$, *guaiacol biniodide*, $C_6H_2I_2\begin{cases}OH\\OCH_3\end{cases}$, *guaiacol-ethyl*, *guaethol*, *guaiacol valerianicum*.

Medical Properties. Guaiacol was originally proposed as a substitute for creosote in the treatment of *phthisis*, and has been especially commended by Max Schueller, of Berlin. According to the belief of Max Schueller, it acts in all forms of *tuberculosis* by affecting the tubercle bacillus, and is useful not only in surgical, but also in *external tubercle*, including *lupus*. Schueller at one time used it largely by inhalation, employing an aqueous solution of one part to six hundred. Recently he teaches that the inhalation should not be used unless there is tubercular catarrh of the respiratory mucous membrane. He administers it, from two to three drops to children, three to five drops to adults, four times a day, in milk or in wine, continuing the use for many months.

It has been asserted that guaiacol does good in *pulmonary tuberculosis* by forming compounds in the blood with the toxic by-products of the tubercle bacillus and aiding their elimination. Guaiacol has been used hypodermically, but the method does not seem justifiable. As an antipyretic in *typhoid* and other fevers, from twenty to forty drops of it painted on the previously well-washed skin of the abdomen and covered with some impermeable dressing are often very effective, the temperature sometimes being reduced as much as six or more

degrees; but the frequent occurrence of collapse has led to the abandonment of the method.

Certain derivatives of guaiacol have been found efficient substitutes for guaiacol in tuberculosis, given in doses of eight grains increased up to one and a half drachms a day; of these the best is the carbonate.

Guaiacol Benzyl Ether or *Pyrocain* occurs in colorless crystals, soluble in ether and melting at 62° C. It possesses the general therapeutic properties of guaiacol.

Guaiacol Biniodide, a reddish-brown powder, with something of the iodine odor, soluble in alcohol and fatty oils, has been proposed by Vicario as a local application in tuberculosis.

Guaiacol Bisulphonate of Quinine or *Guaiaquin*. $(C_6H_4O_2CH_3HSO_3)_2C_{20}H_{24}N_2O_2$. Guaiaquin is an acid salt, occurring as a yellowish crystalline powder, very soluble in water, alcohol, and dilute acids, and of a bitter taste. It contains 44·26 per cent. of alkaloid quinine, combined with 55·74 per cent. of guaiacol sulphonic acid, the latter being equivalent to 33·38 per cent. of pure guaiacol. It has been brought forward as an anti-malarial remedy and a gastro-intestinal stimulant and antiseptic. Dose, as a tonic, from three to six grains (0·19–0·39 Gm.); as an antiperiodic, ten grains (0·65 Gm.) three times a day.

Guaiacol Carbonate or *Duotal* $[CO_3(C_6H_4OCH_3)_2]$ is prepared by decomposing guaiacol in a solution of soda with carbonyl chloride. It is a neutral white crystalline powder having a slight taste and odor, insoluble in water and cold alcohol, soluble in ether, chloroform, benzene, and boiling alcohol, slightly soluble in fixed oils and glycerin. Dose, from three to eight grains (0·2–0·5 Gm.).

Guaiacol Cinnamate or *Styracol*. It is asserted that this substance is broken up into cinnamic acid and guaiacol in the intestines, and is a useful remedy in *phthisis*, also in *chronic catarrh* of the gastro-intestinal and genito-urinary tracts. (*P. J. Tr.*, March, 1891.)

Guaiacol Ethyl is an oily liquid of an agreeable aromatic odor, soluble in water, which was brought forward as a remedy in tuberculosis, with the statement that it acts upon the human system like guaiacol, but more quickly and energetically. The researches of De Buck (*Belg. Méd.*, 1897) indicate, however, that it is not more effective than is guaiacol in tubercular diseases. It is affirmed, however, to be a pronounced analgesic, which when applied to the skin by means of a brush is rapidly absorbed, and in cases of *neuralgia* or *neuritis* produces great relief. It may also be used subcutaneously in 10 per cent. emulsions with sterilized glycerin, and has been so applied; this glycerin solution has also been successfully used in *cystitis*.

Guaiacol Iodoform is a reddish-brown syrupy liquid, which is really a solution of iodoform in guaiacol. It has been used hypodermically for *tuberculosis*, in doses of three cubic centimetres diluted with sixteen parts of olive oil.

Guaiacol Phosphate. Phosphoric Guaiacyl-ether has been shown by A. Gilbert (*Sem. Méd*, 1897) to be split up in the intestines, with the liberation of its constituents, and to afford, therefore, a method of administering guaiacol, over which it has the advantage of being innocuous to the mucous membrane of the stomach. It would appear, however, much less active and much more uncertain in its influence than is guaiacol.

Guaiacol Phosphite. $P(OC_6H_4OCH_3)_3$. *Phospho-guaiacol. Phosphite of Guaiacyl-ether* is a white crystalline powder, possessing a sharp taste and indifferent odor. It is soluble in water, dissolves very freely in alcohol, ether, chloroform, acetone, benzene, toluol, and the fatty oils, but it is sparingly soluble in oil of turpentine and in glycerin. Melting point, 77·5° C. It contains 92·25 per cent. of guaiacol, and was introduced in 1897 by Ballard. (*Rép. de Pharm.*, 1897.) It is but slightly poisonous, and probably is capable of acting as do other preparations of guaiacol.

Guaiacol Salol is probably decomposed in the alimentary canal, and has been used as an intestinal antiseptic in *diarrhœas* and *dysenteries*. It has also been employed in *phthisis* and in *rheumatism*. The dose is one gramme, repeated at short intervals, up to ten grammes a day.

Guaiacol Valerianate or *Geosote* is used for similar purposes as the other preparations of guaiacol, in the same doses as the carbonate. According to Rieck (*Deut. Med. Zeitung*, Aug. 1897), it is especially valuable as a local application in tubercular diseases of the bones; by injection or in other ways brought in direct contact with the diseased tissue.

GUAIPEROL. *Piperidin Guaiacolate.* This salt occurs in colorless crystals, having a feeble creosote odor, soluble in water 1 to 30, freely soluble in alcohol, and has been used to a moderate extent. (*Brit. Med. Journ.*, vol. ii. 1898.) In doses of from five to ten grains (0·33–0·65 Gm.) in capsules, three times a day, after meals, in *phthisis* it is said to lessen cough, increase the appetite, and cause general improvement.

GUANO. *Bird-manure.* This is a valuable manure, consisting of the decomposed excrement of countless aquatic birds, which has accumulated for ages on certain barren and uninhabited islets of the western coast of South America and in other localities throughout the world. Guano is a coarse dry powder of a brown color. Exposed to the air it absorbs moisture, and becomes somewhat sticky. Its smell is offensive and slightly ammoniacal. With the powder are intermingled friable lumps, which exhibit in their inside whitish specks, and which, when exposed to the air, fall to powder, exhaling an ammoniacal smell. It is soluble in great part in water, and the solution formed contains chiefly ammonium oxalate. When exposed to heat it blackens, burns with a slight flame, exhales the smell of ammonia, and leaves a whitish ash, varying in amount from 27 to 35 per cent. The value of guano as a fertilizer depends chiefly upon the proportion of the organic ingredients, the phosphates being of secondary importance. M. E. Baudrimont infers, from the analyses of seventeen samples of Peruvian guano, that the proportion of nitrogen may be obtained approximately by dividing the amount of the organic matters by five. The samples varied greatly in value. (*Journ. de Pharm.*, Oct. 1857.) Crystals of ammonium carbonate have often been observed in guano. Colombian guano was found by Dr. C. Morfit, of Baltimore, to be rich in phosphoric acid and lime. (*Chem Gaz.*, Dec. 1, 1855.) Unger obtained from Peruvian guano, in 1845, a peculiar substance, called *guanine*, $C_5H_5N_5O$. (See *Journ. de Pharm.*, 4e sér., xvii. 328.) By the oxidation of guanine, as well as by other processes, chemists have prepared *guanidin*, CH_3H_5, and from this in turn a series of derivatives. For

an elaborate investigation of the chemistry and physiological action of these substances, see *Arbeiten des Pharmak. Inst. zu Dorpat*, Bd. vii.–xii. By the action of nitrous acid upon guanine there is produced the base *xanthine*, $C_5H_4N_4O_2$, and Emil Fischer has recently shown that *theobromine* and *caffeine* are capable of being produced from xanthine, and are, in fact, dimethyl- and trimethyl-xanthine respectively. (*A. J. P.*, 1882, 218.) Guano is a powerful local irritant, which, when mixed with equal parts of potters' clay or other diluent, is capable of causing vesication. It has been used as a counter-irritant and also as a stimulant in certain *cutaneous diseases*, especially in *eczema*, *ecthyma*, and *tinea capitis*. For various preparations of guano, see 16th ed. *U. S. D.*

GUAREA PURGANS. *Gito.* The root and bark of this Brazilian plant are said to be drastic purgatives.

GUTTA-PERCHA. This valuable concrete juice was first brought into notice by Dr. Wm. Montgomerie, a British army surgeon, who in 1843 sent specimens from Singapore to Europe. It was originally altogether or in chief part a product of a large saponaceous tree, formerly recognized by the Pharmacopœias as *Isonandra gutta*, which grows in the southern extremity of the Malay Peninsula and the neighboring islands. Its trunk, which sometimes reaches six feet in diameter, has numerous ascending branches which are crowded at their extremities with petiolate, oblong leaves, four or five inches long by two in breadth, bright green above and brownish beneath, and giving origin to small white flowers. This tree is the *Dichopsis gutta* of Benth. and Hook. The gutta-percha-yielding Isonandra and Dichopsis have been referred by Engler to the genus *Palaquium*, which includes about fifty species, of which the most important as yielding the gutta-percha are *P. gutta* (Hook.), Burck.; *P. oblongifolium*, Burck.; *P. borneense*, Burck.; and *P. treubii*, Burck. Inasmuch, however, as it appears that *P. gutta*, (Hook.), Burck., has been practically exterminated, the commercial product from the Indian Archipelago is yielded by the remaining three species and *Payena leerii* (Teysm. and Binnd.), Benth. and Hook., a closely related genera of the same natural order. It seems further that *Palaquium borneense*, Burck. (of Borneo), and *P. treubii*, Burck. (of Banca), have also disappeared in their respective countries. *P. oblongifolium*, Burck. (of Malacca, Riouw, Sumatra, and Borneo), yields the best gutta-percha, being homogeneous, compact, and elastic; upon treatment with warm water, it may be made into any form, and upon cooling stiffens. *Payena leerii* (Teysm. and Binnd.), Benth. and Hook. (of Borneo, Banca, Amboina, Sumatra, and Malacca), yields a product which is lighter in color, less elastic, and more fibrous. Further, it is probable that gutta-percha-like materials are yielded by numerous tropical or subtropical trees. Thus, according to Prof. Engler, four different species of trees in King Wilhelm's Land produce such a concrete juice. (*P. J. Tr.*, 1896, lvii.)

In Singapore the gutta-perchas of various sources are mixed, and three commercial articles are sold,—viz. (1) first quality, (2) medium quality, (3) white gutta-percha. The exportations from Singapore (which port furnishes the bulk of all the gutta-percha of commerce) amount to four and a half million kilogrammes annually, valued at three and a quarter million dollars. As found in commerce, gutta-percha is generally impure, containing fragments of vegetable matter and earth. From these it may be freed by kneading it in hot water, or by melting it with oil of turpentine, straining, and evaporating. It may also be purified by means of chloroform. One part of gutta-percha cut into small pieces, put into a flask with twenty parts of chloroform, and frequently shaken, will be fully dissolved in two or three days. To this solution, which cannot be readily filtered, add one-fourth of a part of water, shaking the mixture, and then allowing it to rest for two weeks. The impurities rise or sink, and the clear intervening liquid yields pure gutta-percha by the distillation of the chloroform. (*Chem. Centralbl.*, Feb. 1857, 108.) A more satisfactory method is probably by dissolving one part of gutta-percha in twenty of boiling benzene, shaking the solution frequently with calcium sulphate, which upon standing two or three days carries down with it the coloring matter, then decanting the clear liquid, and adding it, in small portions at a time, to alcohol, agitating continually. During this process the gutta-percha is deposited perfectly white. Thorough desiccation requires an exposure of several weeks, but it may be hastened by rubbing in a mortar. (*Journ. de Pharm.*, Août, 1863, 138.)

Gutta-percha is of a dull white or whitish color, often with reddish-brown streaks, of a feeble odor, tasteless, at ordinary temperatures hard and almost horny, somewhat flexible in thin pieces, having an unctuous feel under the fingers, and very tenacious. Its sp. gr. is 0·9791. (Soubeiran.) At about 49° C. (120° F.) it becomes softer and more flexible, but is still elastic, resisting, and tenacious. At from 66° to 71° C. (150°–160° F.) it is soft, very plastic, and capable of being welded and moulded into any form; "plastic above 120° F. (48·8° C.)." *Br.* It can be softened either by means of hot water or by dry heat. On cooling, it reassumes its former state, and retains any form which may have been given to it. In the softened state it is readily cut with a knife, though with some difficulty when cold. Exposed to a heat of 166° C. (330° F.), it loses a portion of water, and on hardening becomes translucent and gray; but it recovers its original characters if immersed in water. Subjected to igneous distillation, it yields volatile products resembling closely the volatile oil obtained from caoutchouc by the same process. Heated in an open vessel, it melts, foams up, and takes fire, burning with a brilliant flame and much smoke. A portion thus melted retains the state of a viscid fluid on cooling. Gutta-percha is a non-conductor of electricity. It is insoluble in water, alcohol, alkaline solutions, and the weak acids. Ether and the volatile oils soften it in the cold, and imperfectly dissolve it with the aid of heat. Oil of turpentine dissolves it perfectly, forming a clear, colorless solution, which yields it unchanged by evaporation. It is also dissolved by carbon disulphide, chloroform, and benzene and benzin. According to Soubeiran, it contains, besides pure gutta-percha, small portions of a vegetable acid, casein, and two resins, one soluble in ether and oil of turpentine, the other in alcohol. (*Journ. de Pharm.*, 3e sér., xi.) Freed from these impurities, it has an ultimate composition closely analogous to if not identical with that of caoutchouc. For a particular account of the distinctive properties of pure gutta-percha, and the two resins mixed

with it, the reader is referred to an article by M. Payen in the *Journ. de Pharm.* (3e sér., xxii.), also in the *Chem. Gaz.* (x.). According to Baumhauer, pure gutta-percha, as it issues from the tree, is a hydrocarbon, with the formula $C_{10}H_{16}$, which he calls *gutta*, and by the oxidation of which, in various degrees, the different bodies constituting gutta-percha are produced. This hydrocarbon can be separated by treating gutta-percha with dilute hydrochloric acid, and boiling the residue with ether, which deposits the gutta on cooling; but the ethereal treatment must be frequently repeated to obtain it quite pure (*Journ für prakt. Chem.*, lxxviii. 279.) M. Arppe considers gutta-percha as a mixture of six different resins, which may have been formed from a hydrocarbon, $C_{10}H_{16}$. (See *Chem. Gaz.*, ix. 471.) Oudemans (*Jahresber.*, 1859, 517) finds two resinous products in gutta-percha: *fluavil*, fusing at 42° C., with the formula $C_{20}H_{32}O$, and soluble in cold alcohol, and *albane*, fusing at 140° C., with the formula $C_{10}H_{16}O$, and soluble in chloroform, carbon disulphide, and ether, from which last it crystallizes out on cooling. Gutta-percha resists putrefaction strongly; but in certain situations, as when employed to protect underground telegraph wires passing near the roots of the oak, it has been observed to undergo speedy decomposition, in consequence, it is supposed, of the action of fungi. (*P. J. Tr.*, xvii. 193.)

The concrete juice of the Abyssinian trees *Mimusops schimperi*, Hochst., and *M. kummel*, Bruce (nat. ord. Sapotaceæ), have been found by Heckel and Schlagdenhauffen to contain 48·20 per cent. of gutta, 42·80 per cent. of an amorphous resin, and 9·80 per cent. of inorganic salts. They seem, however, to serve the purposes of the arts only when mixed with true gutta-percha. Under the name of *balata*, the concrete juice of *Sapota mulleri*, or *Bully-tree*, which is abundant in Dutch Guiana, has been imported into England. It is said to be more durable than and equally elastic with gutta-percha, while requiring much greater heat to soften.

Gutta-percha has been applied to many useful and ornamental purposes. Its plasticity when moderately heated, great firmness and tenacity at ordinary temperatures, and insolubility in water and alcohol are the properties to which it chiefly owes its value. By immersing it in hot water it is made susceptible of being formed into any desirable shape, so that utensils of various kinds, ornamental impressions, casts, sheets, bands, cords, sticks, tubes, etc., applicable to numerous purposes in the arts, may be made from it with great facility. To give it greater pliability, it is sometimes mixed with the tar resulting from the igneous decomposition of caoutchouc, or with its own tar and lampblack. It may be vulcanized in the same manner as india-rubber, and undergoes a similar change of properties. In the dissolved state it may be employed as a varnish, impervious to moisture.

Gutta-percha has no medicinal properties, but is used in surgery for the formation of splints or other external artificial supports, as well as in the manufacture of various surgical instruments. The pure gutta-perch, when softened by immersion in warm water, may be moulded without difficulty into any form. For the method of application, the reader is referred to works upon surgery. Gutta-percha is also largely used by dentists for filling various cavities in teeth. For this purpose it is mixed with zinc oxide, silica, finely powdered glass, or other mineral substance, to give it density and firmness. Another application of gutta-percha is to serve as a vehicle of certain caustic substances, particularly zinc chloride and caustic potassa. The preparation is made by reducing the caustic substance to fine powder, and then thoroughly mixing it with its weight of gutta-percha, melted at the lowest possible temperature.

GYMNEMA SYLVESTRE. This is a woody climber, belonging to the Asclepiadaceæ, which grows in India and also in Africa. The root has for a long time been employed by the natives as a remedy in snake-bite, and it is affirmed by Dr. T. Dyer (*Nature*, 1887) that directly after the eating of one or two leaves it is impossible to taste sugar, though other tastes are not obscured. Thus, pungency alone is detected in gingerbread, and a sweet orange tastes like a lime. The active principle, *gymnemic acid*, was discovered by Mr. Hooper, and has been used with considerable success as a remedy for *parageusis* and *hallucinations of taste*. The 1 per cent. aqueous solution is to be applied with a brush to the inside of the mouth, or a hot infusion (15 per cent.) of the crude drug may be used. (See *Therap. Monatssh.*, Bd ix.)

GYMNOCLADUS CANADENSIS. Lam. (Now *G. dioica* (L.), Koch.) *Coffee-tree. Kentucky Mahogany.* (Nat. ord. Leguminosæ.) According to Bartholow, the aqueous extract of the so-called seeds is toxic. (*Amer. Drug.*, April, 1886.) Samuel S. Mell (*A. J. P.*, 1887, 230) obtained from them by petroleum benzin about 10 per cent. of fixed oil which is yellowish, saponifiable, and of sp. gr. 0·919. Ether extracted a little wax, fat, and resin. A little tannin and a small quantity of glucoside were also obtained. This latter had a peculiar odor and an acid burning taste. Jas. H. Martin (*A. J. P.*, 1892, 558) has examined the various parts of the plant, with similar results, obtaining a yellow saponifiable oil from the bean and the bark, and a glucoside from the pulp.

GYNOCARDIA ODORATA. R. Br. *Chaulmoogra.* (Nat. ord. Bixineæ.) This is an East India plant, the oil of which has been largely employed, with asserted benefit, in elephantiasis or the leprosy of the East. The fruit is a succulent indehiscent pericarp, which yields a fixed oil by expression. Chaulmoogra oil, as it occurs in commerce, is solid at 42° C. (107·6° F.), of a whitish color, sometimes tinged with brown, and is usually prepared by expressing the kernels of the seed. It is sometimes prepared by boiling the crushed seeds with water and separating the oil. It has an acid reaction to litmus-paper, melts at 42° C. (107·6° F.), and at this temperature its sp. gr. is 0·930. Alcohol dissolves a considerable portion of it, whilst ether, chloroform, carbon disulphide, and benzin dissolve it freely. John Moss (*P. J. Tr.*, x. 251) found in chaulmoogra oil, *gynocardic acid* 11·7, *palmitic acid* 6·3, *hypogœic acid* 4, *cocinic acid* 2·3 per cent. in combination with glyceryl as fats, whilst gynocardic and palmitic acids were also found in the free state; the activity of the oil he believes to be due to gynocardic acid, and states that the green coloration produced by treating the oil with sulphuric acid (Dymock's test) can also be obtained by treating palm oil in the same manner, yet purified gynocardic acid gives the same green color. *Gynocardic acid* has a yellowish color, forms crystalline plates, melting at 29·5° C. (80° F.), has an acrid burning taste, and is probably of the formula $C_{14}H_{24}O_2$.

The chaulmoogra seeds are in themselves an article of commerce, and are sometimes given internally in place of the oil in doses of six grains (0·39 Gm.). Chaulmoogra oil is said at present to be very largely used in England, being sold by the ton, as a local application to open *sores*, *wounds*, *sprains*, etc., in domestic animals, and to be officially employed in the English cavalry and artillery. It is also said to be employed against *bruises*, *sprains*, *rheumatism*, and *stiffness* by sportsmen and athletes. In *leprosy* it is given internally, and also applied regularly and freely externally, and seems to be one of the most useful of known drugs. It has also been given with asserted benefit in various forms of *external syphilis*, *ichthyosis*, and in other chronic skin diseases. The dose of the oil is from five to ten minims (0·3–0·6 C.c.), gradually increased, but administered in capsule or in olive oil solution. *Gynocardic acid* is sometimes used as a substitute for chaulmoogra oil internally in doses of from one-half to two grains, (0·03–0·13 Gm.) or externally dissolved in oil (1 to 10 or 30). According to Dr. J. Moeller, the commercial seed is not the product of *Gynocardia odorata* alone. For a description of seed and plants, see *P. J. Tr.*, xv. 321.

HÆMOGLOBIN. *Hemoglobin.* A constituent of venous blood, passing in the arterial blood into oxyhæmoglobin. Its molecular formula is extraordinarily complex, the hæmoglobin from the blood of swine having, according to some writers, the formula $C_{609}H_{1005}N_{156}S_3FeO_{179}$, while that from dogs' blood is given as $C_{636}H_{1025}N_{164}S_3FeO_{189}$. Various preparations of *desiccated blood* containing hæmoglobin have been put upon the market. Crystals of hæmoglobin may be obtained from the blood of certain animals (guinea-pigs, rats, etc.) with ease by simply adding water to the blood. The hæmoglobin dissolves in the water, the corpuscles separating, and the crystals form in a few minutes. Another method consists in adding to defibrinated blood 6 per cent. of its volume of ether, or a mixture of alcohol and ether; on shaking the mixture, the corpuscles dissolve, and a thick magma of crystals forms sooner or later; these may be purified by washing with 25 per cent. alcohol and by recrystallization. Freezing has been resorted to for the purpose of separating the crystals.

Ferrohemol is a brown, almost tasteless, powder containing 3 per cent. of iron, which is made by the precipitation of blood by a dilute solution of iron and neutralization with soda. *Fer cremol* is a similar substance.

Hemol, *Hemogallol*, are made, as suggested by Prof. Kobert, by the action of reducing agents upon the blood-coloring matter. (See *E. Merck's Jahresber.*, 1891.) With the hemol, zinc-dust is used as the reducing agent; with the hemogallol, pyrogallol is used. The former is a dark brown, the latter a red-brown tasteless powder.

Either of these blood derivatives may be used in doses of from five to ten grains (0·33–0·64 Gm.), but there is no sufficient reason for believing that they have any superiority over the older preparations of iron.

HAPLOPAPPUS BAYLAHUEN. (Now *Aplopappus Baylahuen*, Remy.) *Hysteronica Baylahuen.* This composite herb is a native of Chili, where it is said to be relied upon as a stimulant in *flatulent dyspepsia* and *chronic inflammation* with *hemorrhage* of the lower bowels. It has been analyzed by Dr. H. H. Rusby (*A. J. P.*, 1890, 488), and later by H. Kahn (*A. J. P.*, 1891, 377). The former found a volatile oil, a fatty oil which had the specific odor of the plant, a brown acid resin of sharp taste, and tannin. The latter determined the percentage of volatile oil as 6·65, and of resin as 21·15. He also considers that this resin is a mixture of four different resins. Dr. G. Baille asserts (*Bull. Gén. de Thérap.*, Feb. 1889) that the remedy is valuable not only in *dysentery*, but in genito-urinary catarrhs, and also as a stimulating expectorant. A strong decoction, one part to five, may be given, from one to two tablespoonfuls every two hours; a better preparation is the fluid extract, dose, from five to twenty minims (0·3–1·23 C.c.).

HARTSHORN. *Cornu.* Lond., Ed. Ph. The horn of the Cervus Elaphus, or stag. (See 16th ed. *U. S. D.*)

HEDERA HELIX. L. *Ivy.* (Nat. ord. Araliaceæ.) This well-known evergreen creeper is a native of Europe. The fresh *leaves* have a balsamic odor, especially when rubbed, and a bitterish, harsh, unpleasant taste. They are used for dressing issues, and, in the form of decoction, have been recommended in *sanious ulcers* and *cutaneous eruptions*, particularly *tetter* and the *itch*. The *berries*, which have an acidulous, resinous, somewhat pungent taste, are said to be purgative and even emetic. MM. Vandamme and Chevallier discovered in ivy seeds a peculiar very bitter alkaline principle, *hederine*. It is obtained by treating the seeds with calcium hydrate, dissolving the precipitated alkaloid in boiling alcohol, and evaporating the alcoholic solution. (*A. J. P.*, xiii. 172.) Prof. Posselt has discovered two acids in the seeds, one of which has their taste in a high degree, and was named by him *hederic acid*, the other he did not obtain quite pure. (See *Chem. Gaz.*, 1849, 93.) The seeds were also found to contain a variety of tannic acid, turning ferric salts dark green, to which Posselt gave the name of *hedera-tannic acid.* (*Ann. Ch. und Phar.*, 69, p. 62.) Dr. F. A. Hartsen has found in the leaves a crystalline glucoside allied to saponin. (*A. J. P.*, 1875, xlvii. 268.) Davies and Hutchinson confirmed the existence of Posselt's hederic acid, and gave it the formula $C_{16}H_{26}O_4$. Kingzett believes that it is not an acid, but a glucoside. J. Vernet (*Ber der Chem. Ges.*, xiv. 685) obtained a glucoside, which separated from solution in boiling acetone in silky needles, melting at 233° C., insoluble in water, chloroform, and ligroine, slightly soluble in cold acetone, benzol, and ether, more soluble in hot alcohol and hot alkalies. Its formula he gives as $C_{32}H_{54}O_{11}$, and states that it decomposes on heating with dilute sulphuric acid into a body, $C_{26}H_{44}O_6$, which fuses at from 278°–280° C., and a non-fermentable sugar which reduces Fehling's solution. (*Year-Book of Ph.*, 1877, 508.) From the trunks of old ivy plants, growing in the south of Europe and the north of Africa, a resinous substance exudes through incisions in the bark, which has been employed in medicine under the name of *ivy gum.* It is in pieces of various sizes, of a dark yellowish-brown color, sometimes inclining to orange, more or less transparent, sometimes of a deep ruby-red color internally, of a vitreous fracture, pulverizable, yielding a lively orange-yellow powder, of a peculiar not disagreeable odor when heated or inflamed, and of a bitterish resinous taste. Its chief constituent is resin, though some pieces

contain a considerable proportion of bassorin, and others large quantities of ligneous matter. It was formerly used as a stimulant and emmenagogue, but is now scarcely employed. Placed in the cavities of carious teeth, it is said to relieve *toothache.* The light and porous *wood* of the ivy is sometimes used for making *issue-peas.*

HEDWIGIA BALSAMIFERA. Engl. (Now *H. panamensis*, Engl.) *Bois Cochon*, or *Sucrier de Montagne.* (Nat. ord. Burseraceæ.) This native of the Antilles has been examined by Messrs. Gaucher, Combemale, and Marestang (*La France Méd.*, Oct. 1888), who find in it an alkaloid and a resin. The extract of the root and stems produces in the guinea-pig rapid considerable lowering of temperature, progressive paralysis, general convulsions, dilatation of the pupils, respiratory irregularity, and cardiac paresis. The alkaloid was found to be a convulsive agent, acting upon the spinal cord. The resin, which seemed much more active than the alkaloid, acted as a paralyzant.

HEDYCHIUM SPICATUM. Ham. (Nat. ord. Scitamineæ.) The root of this plant, which is used in India as incense, has been found by Mr. J. C. Thresh to contain *ethylmethyl paracoumarate.* (*P. J. Tr.*, Nov. 8, 1884.)

HELENIUM AUTUMNALE. L. *False Sunflower. Sneezewort. Sneezeweed.* An indigenous perennial, bitter, somewhat acrid composite herb. The leaves and flowers snuffed up in the state of powder produce violent sneezing, and have been used as an errhine. F. J. Koch (*A. J. P.*, 1874, 221) found in the plant a bitter principle believed to be a glucoside, malic acid, traces of tannic acid, albumen, volatile oil, etc. *Helenium nudiflorum*, Nutt., has similar properties; as has also *H. mexicanum. H. tenuifolium*, Nutt., a common roadside weed of Mississippi and Louisiana, is stated by Dr. Galloway to produce in animals muscular twitchings, passing into violent convulsions, terminating in death. In four negroes it caused spasms, with delirium and loss of consciousness. (*A. J. P.*, 1872, 309.)

HELIANTHEMUM. *Frostwort. Herbe de Hélianthème de Canada*, Fr. *Canadisches Sonnenröschen*, G. The herb of the *Helianthemum canadense* (L.), Michx., belonging to the natural order of Cistaceæ, was formerly included in the U. S. Secondary List. The *frostwort, frost-weed*, or *rock rose*, as this plant is variously called, is an herbaceous perennial, from six to eighteen inches high, with a slender, rigid, pubescent stem, oblong, somewhat lanceolate leaves about an inch in length, and large yellow flowers, the calyx and peduncles of which, as well as the branches, are covered with a white down. The flowers which first appear are terminal, few or solitary, large, on short peduncles, with erosely emarginate petals about twice as long as the calyx. Later in the season, or on different plants, other flowers appear, very small, axillary, solitary or somewhat clustered, nearly sessile, sometimes destitute of petals, and usually wanting the two outer sepals of the calyx. The fruit is a capsule, smooth and shining, with brown, scabrous, punctate seeds. Frostwort grows in all parts of the United States, preferring dry sandy soils, and flowering in June in the Middle States. It was William Crutcher (*A. J. P.*, 1888, 390) who found in it volatile oil, wax, fatty oil, tannin, and apparently a glucoside crystallizing in white needles. Fred. J. Kruell found in it *H. corymbosum*, Michx., *tannin* in large proportion, resin, glucose, gum, extractive, chlorophyll, and inorganic salts. (*A. J. P.*, 1874, 358.) Frostwort has an astringent, slightly aromatic, and bitterish taste, and appears to possess tonic and astringent properties; it was formerly employed in *scrofulous diseases.* (See *U. S. D.*, 14th ed.) According to D. A. Tyler (Pamphlet, New Haven, 1846), *H. corymbosum* possesses similar properties, and may be indiscriminately employed with *H. canadense* in *scrofula, diarrhœa*, and *secondary syphilis*, and locally as a gargle in *scarlatina*, and a wash in *prurigo.* Dr. Tyler, however, has known the strong decoction and the extract to produce vomiting. He considers two grains (0·13 Gm.) of the latter a full dose for an adult.

HELIANTHUS ANNUUS. L. *Common Sunflower. Hélianthe, Grand Soleil*, Fr. *Sonnenblume*, G. This very large composite is cultivated in this country, in Europe, and especially in China, chiefly for the sake of the fixed oil yielded by the seed. This oil has a sp. gr. of from 0·924 to 0·926, solidifies at —15° C., is colorless, or yellowish, limpid, nearly tasteless and odorless, and dries slowly. It is said to make an excellent salad dressing, and to be one of the best burning oils known. The increase in cultivation is stated to be nearly a thousandfold, 275 pounds of oil being a fair yield per acre. For particulars as to cultivation, see *A. J. P.*, 1875, 460; also *N. R.*, 1876, 165. Ludwig and Kromayer (*Arch. Pharm.* (2), 99, 1 and 285) obtained a tannin which they called *helianthitannic* acid, and gave it the formula $C_{14}H_6O_8$. On boiling with moderately dilute hydrochloric acid they obtained a fermentable sugar and a violet coloring matter. E. Diek (*Dissertation*, Göttingen, 1878) found only small quantities of *inulin*, large amounts of *levulin*, and a dextro-rotatory sugar. M. Chardon has obtained a peculiar oleoresin from sunflowers grown in Algeria. (*P. J. Tr.*, 1873, 323.) The stalk, when treated as is flax, yields a long, fine fibre, which is said to be used in China for the adulteration of silk. The sunflower also enjoys the reputation of protecting against marsh miasmata. (See *N. Y. Med. Rec.*, 1868, 353.) Dr. Kazatchkoff states (*Bull. Gén. Thérap.*, Oct. 1889) that in the Caucasus the inhabitants employ the sunflower in malarial fevers. The leaves are spread upon a bed covered with a cloth, moistened with warm milk, and then the patient is wrapped up in the spread. Perspiration is produced, and the patient is kept in this condition for an hour or two. The same process is repeated every day until the access of the fever has ceased. The Pah Ute Indians are said to use very freely as food the seeds of two indigenous sunflowers, *H. petiolaris* and *H. lenticularis.* (*Proc. A. P. A.*, xxvii. 178.)

HELLEBORUS FŒTIDUS. L. *Bear's Foot.* (Nat. ord. Ranunculaceæ.) This is a perennial European plant, growing in shady places, and flowering in March and April. It derived its specific name from its offensive odor. The leaves, which are the part used, have a bitterish, pungent, and acrid taste, and when chewed excoriate the mouth. The footstalks are still more acrid. Marmé and Husemann have discovered the same active principles in this as in the other species of Hellebore. (See *Helleborus Niger.*) This hellebore is said by Allioni to be the most acrid and energetic of its genus. It is powerfully emetic and cathartic, and in large doses dangerous. It has long been

used in Great Britain as a domestic remedy for *worms*, and was brought to the notice of the profession by Dr. Bissett, who found it an efficacious anthelmintic, and prescribed it also in *asthma*, *hysteria*, and *hypochondriasis*. M. Decerfs has known it to cause the expulsion of *tænia*. It is given in powder or decoction. The dose for a child from two to six years old is from five grains to a scruple (0·324–1·29 Gm.) of the dried leaves, or a fluidounce of the decoction, made by boiling a drachm of the dried leaves in half a pint of water. This quantity should be repeated, morning and night, for two or three days in succession. A syrup made from the juice of the green leaves is used in England.

HELLEBORUS NIGER. L. *Black Hellebore. Ellébor noir*, Fr. *Schwarze Niesswurzel, Weihnachtswurzel, Winterrose*, G. *Elleboro nero*, It. *Eléboro negro*, Sp. This formerly official rhizome is knotted, blackish on the outside, white within, and sends off numerous long, simple, depending fibres, which are brownish yellow when fresh, but become dark brown upon drying. The leaves are pedate, of a deep green color, and stand on long footstalks which spring immediately from the root. Each leaf is composed of five or more leaflets, one terminal, and two, three, or four on each side, supported on a single partial petiole. The leaflets are ovate-lanceolate, smooth, shining, coriaceous, and serrated above. The flower-stem, which also rises from the root, is six or eight inches high, round, tapering, and reddish towards the base, and bears one or two large, pendent, rose-like flowers, accompanied by floral leaves, which supply the place of the calyx. The petals, five in number, are large, roundish, concave, spreading, and of a white or pale rose color, with occasionally a greenish tinge. There are two varieties of the plant,—*humilifolius* and *altifolius*,—in the former of which the leaves are shorter than the flower-stem, in the latter longer. It is a native of the mountainous regions of southern and temperate Europe, and is found in Greece, Austria, Italy, Switzerland, France, and Spain. It is cultivated in gardens for the beauty of its flowers, which expand in the middle of winter and have thus given it the name of *Christmas rose*. For a history of the use of hellebore by the ancients, see 15th edition *U. S. Dispensatory*.) The roots of various other plants, not belonging to the same genus, are said to be frequently substituted for the black hellebore. They may usually be readily distinguished by attending to the characters of the genuine root.*

The medicine of which we are treating is sometimes called *melampodium*, in honor of Melampus, an ancient shepherd or physician, who is said to have cured the daughters of King Prætus by giving them the milk of goats fed on hellebore.

Though the whole root is kept in the shops, the fibres are the portion usually recommended. They are about as thick as a straw, when not broken from four inches to a foot in length, smooth, brittle, externally black or deep brown, internally white or yellowish white, with little smell, and a bitterish, nauseous, acrid taste. In their recent state they are extremely acrimonious, producing on the tongue a burning and benumbing impression, like that which results from taking hot liquids into the mouth. This acrimony is diminished by drying, and still further impaired by age. MM. Feneulle and Capron obtained from black hellebore a volatile oil, an acrid fixed oil, a resinous substance, wax, a volatile acid, bitter extractive, gum, albumen, potassium gallate, acid calcium gallate, a salt of ammonia, and woody fibre. Mr. William Bastick discovered *helleborin*, which he obtained in white, translucent crystals, of a bitter taste with a tingling effect on the tongue, not volatilizable, slightly soluble in water, more so in ether and alcohol, and more readily in these liquids hot than cold. (*P. J. Tr.*, xii. 274.) Water and alcohol extract the virtues of the root, which are impaired by long boiling.

Marmé and Husemann obtained from black and green hellebore a glucoside, *helleboreïn*, $C_{28}H_{44}O_{15}$, by precipitating a solution of an extract of the root with solution of lead subacetate, freeing from lead by hydrogen sulphide, and again precipitating with phospho-molybdic acid; by boiling with acid it separated into glucose and *helleboretin*, $C_{14}H_{20}O_3$, a compound of a fine violet color. The helleboreïn exists both in the root and leaves. It has a taste at once sweet and bitter, is soluble in water and weak alcohol, much less so in ether and absolute alcohol, and is crystallizable in rhomboidal prisms. It is precipitable by tannic acid and mercurous acetate (*Journ. de Pharm. et de Chim.*, 4e sér., ii. 258). Husemann and Marmé (*Ann. Ch. und Phar.*, 135, 61) also examined more thoroughly the *helleborin* of Bastick. They ascribe to it the formula $C_{36}H_{42}O_6$, and find that when boiled with dilute sulphuric acid, or, better, zinc chloride, it is converted into sugar and *helleboresin*, $C_{30}H_{38}O_4$. They obtain this glucoside by treating with hot water the green fatty matter which is dissolved out of the root by boiling alcohol. Though both the principles referred to by the German chemists mentioned are poisonous, the products of their decomposition are said to be harmless. Neither of them is volatile. Helleboreïn is strongly irritant to the mucous membranes, causing, when applied to the conjunctiva, redness, swelling, and increased secretion with indirect enlargement of the pupil, and to the nasal membrane, sneezing, though in less degree than veratrine. Small doses produce little effect on the stomach; but, repeated and accumulated, they cause anorexia, nausea even to vomiting, pain, increased secretion, and inflammation both of the stomach and bowels. It is claimed for *helleboreïn* that it acts upon the heart in a manner similar to digitalis, in small repeated doses slowing the pulse and increasing the force, in toxic doses increasing the rapidity of the pulse, and in most cases causing a sudden cardiac arrest in systole. The blood-pressure in the earlier stages of the poisoning is always increased. Respiration continues after the arrest of the heart. It is affirmed

* A root said to be not infrequently substituted for or mixed with the genuine, and often to be met with in the shops of this country, is thought to be that of the *Actæa spicata*, L. (nat. ord. Ranunculaceæ), of Europe. This has been particularly described by Dr. Carson. (*A. J. P.*, xx. 163.) The points of difference upon which that writer especially insists are the diffuse, jointed, stem-like character of the caudex of the false root, the straggling, separated, and horizontal arrangement of the fibres, and their dense, woody structure and reddish-brown color, contrasted with the thickness, double-headed form, and sponginess of the genuine caudex, the close-set, perpendicular position of its fibres, and their wrinkled appearance, soft texture, and grayish-brown color. The transverse section of the fibre of the Actæa presents the appearance of a cross, which is not obvious in that of the black hellebore, though the central point of this, if closely examined, will be found to present a somewhat stellate appearance. In the *P. J. Tr.* for Aug. 1861 (p. 112), Prof. Bentley states that solution of ferric chloride produces little change of color and little or no precipitation with an infusion of black hellebore, while with a similar infusion of the Actæa root it causes a deep blue or black color and a copious precipitate.

also to increase secretion, especially the saliva and the urine, and probably to have an action upon the uterus. In very large doses it acts upon the nervous system so as to produce partial paralysis with tremors, which if the dose has been sufficiently large are replaced by violent convulsions. The pupil is variously affected; usually it is dilated before death. There are no characteristic post-mortem lesions. As yet the alkaloid has not been found in the secretions, and it may be destroyed in the system. The *helleborin* of Marmé and Husemann is a more active poison, though less irritant to the mucous membrane. It acts on the tongue like aconite. Its influence appears to be directed especially to the nervous system. In the lower animals it causes quickened breathing, restlessness, tension and trembling of the muscles, uncertainty of movement; then retardation of the breathing and pulse, irritability of the peripheral nerves, dilatation of the pupil, loss of hearing, and finally almost complete anæsthesia, with cerebral and spinal congestion, even to apoplexy.

Black hellebore is a drastic hydragogue cathartic, formerly supposed to be possessed of emmenagogue powers. In overdoses it produces inflammation of the gastric and intestinal mucous membrane, with violent vomiting, hypercatharsis, vertigo, cramp, and convulsions, which sometimes end in death. The fresh root applied to the skin produces inflammation and even vesication. The medicine was very highly esteemed by the ancients in *mania*, *melancholy*, *amenorrhœa*, *dropsy*, and *epilepsy*. *Bacher's pills*, celebrated for the cure of *dropsy*, consisted chiefly of black hellebore. The dose of the powdered root is from ten to twenty grains (0·648–1·29 Gm.) as a drastic purge, two or three grains (0·13–0·19 Gm.) as an alterative. Dose of the decoction (two drachms to a pint), a fluidounce every four hours till it operates. Prof. S. B. Botkin and Dr. N. Ischistowitsch (*Centralb. für Med. Wissen.*, July 9, 1887), as the result of experiments made with the extract of the root of a green hellebore, conclude that in moderate doses it lessens the rapidity and increases the force of the cardiac contractions, producing a rise in the arterial pressure, the slowing of the beat being the result, at least in part, of stimulation of the inhibitory nerves, since it is prevented by severing of the vagi or by injections of atropine. The cause of the rise of the arterial pressure is believed by the experimenters to be in part due to increased work of the heart, and in part to contraction of the capillaries by an action of the remedy directly upon their coats. Usually the pulse has been increased in force and diminished in frequency and the secretion of urine notably augmented. The results obtained by Prof. Botkin have been largely confirmed by Dr. Christovich. (*Deutsch. Med. Zeitung*, Jan. 1888.) Ischistowitsch has seen fifteen drops of a solution of 1 to 100 of the aqueous extract every two hours produce in six cases of cardiac diseases a diminution in the frequency and an augmentation of the force of the cardiac pulsations, an increase in the quantity of urine, and a prompt disappearance of the symptoms of non-compensation. Messrs. Venturini and Gaspairini (*Bull. Gén. Thérap.*, June, 1888) state that helleborein is a local anæsthetic, which, in *affections of the eye*, is preferable to cocaine, because of the great permanency of the anæsthesia, and because neither the pupil nor the intraocular pressure is affected. They use from three to four drops of the solution, each drop of it representing $\frac{1}{161}$ grain (0·0004 Gm.). Hypodermically injected, helleborein is stated also to act as a local anæsthetic, but its powerful influence upon the heart forbids this method of use.

HELONIAS DIOICA. Pursh. (*Chamælirium carolinianum*, Willd.; *C. luteum* (L.), A. Gray.) *False Unicorn Plant. Starwort.* This is a small perennial herbaceous plant, growing in most parts of the United States, in shady and hilly situations. Pursh says that the bulbous root is used in colic. Dr. Braman has found it peculiarly efficacious (dose, a drachm and a half three times a day) in *atony of the generative organs*, and in *leucorrhœa*. (*Bost. Med. and Surg Journ.*, xl.)

HEPATICA. *Liverwort. Herbe de Hépatique*, Fr. *Edelleberkraut*, G. Under this name were formerly included in the Secondary List of the U. S. Pharmacopœia the leaves of *H. triloba*, Chaix. (*Anemone Hepatica*, L.; *Hepatica Hepatica* (L.), Karst.) There are now two generally acknowledged species of the ranunculaceous genus Hepatica growing in this country. Both have a perennial fibrous root, with three-lobed leaves, cordate at their base, coriaceous, nearly smooth, glaucous, and purplish beneath, and supported upon hairy footstalks from four to eight inches long, which spring directly from the root. The scapes or flower-stems are several in number, of the same length with the petioles, round, hairy, and terminating in a single white, bluish, or purplish flower. The calyx is at a little distance below the corolla, and is considered by some an involucre, while the corolla takes the name of the calyx. In *H. acutiloba*, D. C. (*Anemone acutiloba*, Laws.; *Hepatica acuta* (Pursh), Britt.), the leaves are cordate, with from three to five entire, acute lobes; and the leaflets of the calyx are acute. In *H. triloba*, Chaix, the leaves are cordate-reniform, with three entire, roundish, obtuse lobes; and the leaflets of the calyx are obtuse. Both are indigenous, growing in woods upon the sides of hills and mountains; the former, according to Eaton, preferring the northern, the latter the southern exposure. The leaves resist the cold of the winter, and the flowers make their appearance early in spring. The whole plant is used. It is without smell, and has a mucilaginous, somewhat astringent, slightly bitterish taste. Water extracts all its active properties. Liverwort is a very mild, demulcent tonic and astringent, supposed by some to possess diuretic and deobstruent virtues: formerly used in *chronic hepatic affections*, and in *hæmoptysis* and *chronic coughs*, it has fallen into complete neglect.

HERACLEUM LANATUM. (Michaux, *Flor. Boreal. Am.*, i. 166.) *Masterwort. Cow-parsnip.* This is one of our largest indigenous umbelliferous plants. The root is perennial, sending up annually a hollow pubescent stem, from three to five feet high, and often more than an inch thick. The leaves are ternate, downy beneath, and supported on downy footstalks; the leaflets petiolate, roundish cordate, and lobed. The flowers are white, in large umbels, and followed by orbicular seeds. This species grows in meadows and along fences and hedges, from Canada to Pennsylvania, and flowers in June. The root, which is the part used, bears some resemblance to that of common parsley. It has a strong disagreeable odor and a very acrid taste. Both the leaves and root excite redness and

inflammation when applied to the skin. Dr. Bigelow considers the plant poisonous. Masterwort appears to be somewhat stimulant and carminative, and has been used in *epilepsy*. (See 16th ed. *U. S. D.*)

HERMODACTYLS. *Hermodactyli.* Under this name are sold in the shops of Europe the roots or bulbs of an uncertain plant, growing in the countries about the eastern extremity of the Mediterranean. By some botanists the plant is thought to be a *Colchicum;* and *C. variegatum* (L. ?), a native of the south of Europe and the Levant, is particularly indicated by Fée, Geiger, and others; while by authors no less eminent the roots are confidently referred to *Iris tuberosa*, L. (nat. ord. Irideæ). They certainly bear a considerable resemblance to the bulb of *Colchicum autumnale*, L., being heart-shaped, channelled on one side, convex on the other, and from half an inch to an inch in length by nearly as much in breadth. As found in commerce, they are destitute of the outer coat, are of a dirty yellowish or brownish color externally, white and amylaceous within, inodorous and nearly tasteless, though sometimes slightly acrid. They are often worm-eaten. Their chief constituent is starch, and they contain no veratrine or colchicine. From this latter circumstance, and from their insipidity, it has been inferred that they are probably not derived from a species of Colchicum. They are in fact almost without action upon the system. It is doubted whether they are the *hermodactyli* of the ancients, which acted like colchicum and were useful in *gout* and *rheumatism*. Pereira describes a bitter variety of hermodactyls, which was brought from India by Dr. Royle. The bulbs are smaller and darker than the others, and have externally a striped or reticulated appearance.

HERNIARIA GLABRA. L. (Nat. ord. Illecebraceæ.) M. Goblez has obtained from this plant a crystalline principle, *herniarine* (*Journ. de Pharm.*, 4e sér., xx. 270), which proves to be *methyl-umbelliferone*, $C_{10}H_8O_3$. Dr. Schneegans has also discovered an alkaloid, *paronychine*. (*A. J. P.*, 1890, 488.) This plant is recommended by Zeissl in *catarrh of the bladder*.

HEROIN. *Diacetic Ester of Morphine.* $C_{17}H_{17}NO_3{<}^{CH_3CO}_{CH_3CO}$. This substance occurs as a colorless, inodorous, crystalline powder, having a faintly bitter taste, insoluble in water, soluble in diluted acids, precipitated by alkalies. It has been investigated by Dreser (*Therap. Monat.*, 1898) and Strube (*Berl. Klin. Wochen.*, 1898), who find that it acts similarly to codeine, but especially affects the respiratory functions. It produces in large dose in the lower animals semi-narcosis, with convulsions, and has very little influence upon the circulation. The breathing becomes deeper and slower, with a slight reduction in the amount of air moved and in the sensitiveness of the respiratory centre to an excess of carbonic acid in the blood. It appears to be neither analgesic nor hypnotic. It is very slightly soluble in water, but its hydrochlorate is freely soluble in water and alcohol, insoluble in ether, and may be used in capsules or solution in the dose of from one-tenth to one-third of a grain (0·007–0·023 Gm.).

HETEROMELES ARBUTIFOLIA. M. Roem. (*Photinia arbutifolia*, Lindl.) (Nat. ord. Rosaceæ.) D. D. Lustig has found in this Californian plant (*toyou* of the Indians) tannic, gallic, and hydrocyanic acids. (*A. J. P.*, April, 1882.)

HEUCHERA. *Heuchera Americana.* L. *H. cortusa.* Michaux. *H. viscida.* Pursh, 187. *Racine d'Heuchère d'Amérique*, Fr. *Amerikanische Sanikelwurzel*, G. The *alum-root* or *American sanicle* is a perennial, herbaceous plant, belonging to the Saxifragaceæ. The leaves are all radical, petiolate, cordate, with rounded lobes, furnished with obtuse mucronate teeth. There is no proper stem; but numerous scapes or flower-stems are sent up by the same root, from one to three feet in height, very hairy in their upper part, and terminating in long, loose, pyramidal, dichotomous panicles. The calyx is small, with obtuse segments; the petals lanceolate, rose-colored, and of the same length as the calyx; the filaments much longer, yellowish, and surmounted by small, red, globose anthers. The whole plant is covered with a viscid pubescence. It is found in shady, rocky situations, from New England to Carolina, and flowers in June and July. The root, which was formerly official, is horizontal, somewhat compressed, knotty, irregular, yellowish, and of a strongly styptic taste. Alum-root is powerfully astringent, and may be employed in similar cases with other medicines belonging to the same class. H. K. Bowman (1869) obtained from it 18 to 20 per cent. of tannin. It has hitherto, however, been little used. J. Peacock (*A. J. P.*, 1891, 174) found a percentage of tannin ranging from 9·33 to 19·66 reckoned on the dry drug, according to the season of the year when collected; also a percentage of starch, calculated the same way, ranging from 5·17 to 16·32. Mr. Frederick Stearns (*Proc. A. P. A.*, 1858, 263) speaks of two other indigenous species, *H. caulescens*, Pursh (now *H. villosa*, Michx.), and *H. pubescens*, Pursh, as having similar properties; and F. W. Anderson reports (*Botan. Gaz.*, 1887, 65) that the roots of *H. hispida*, Pursh, *H. cylindrica*, Douglas, and *H. parvifolia*, Nuttall, are much used by hunters of Montana and others as astringents, particularly in *diarrhœa* caused by the drinking of alkali water.

HIBISCUS ABELMOSCHUS. L. (*Abelmoschus moschatus.* Medic.) (Nat. ord. Malvaceæ.) An evergreen shrub, growing in Egypt, and in the East and West Indies, and yielding the seeds known under the names of *semen Abelmoschi*, *alceæ Ægyptiacæ*, and *grana moschata*. These are of about the same size as flaxseed, kidney-shaped, striated, of a grayish-brown color, of an odor like that of musk, and of a warm somewhat spicy taste. They were formerly considered stimulant and antispasmodic, but are now used only in perfumery. The Arabs flavor their coffee with them. They are said to be employed in the adulteration of musk. Another species, *Hibiscus esculentus*, L., or *Abelmoschus esculentus*, Moench., is cultivated under the name of *okra*, *bendee*, or *qombo* in various parts of the world, for the sake of its fruit, which abounds in mucilage, to which the name of *gombine* has been given, and is used for thickening soup. The leaves are sometimes employed for preparing emollient poultices. The roots, which are a foot or two long, are said also to abound in mucilage free from any unpleasant odor. Their powder is perfectly white, and superior to the marshmallow. The plant is largely cultivated near Constantinople, where it is much used as a demulcent. (*A. J. P.*, 1860, 224.) The bark is also used in making paper and cordage.

HIERACIUM VENOSUM. L. (Nat. ord. Compositæ.) *Rattlesnake Weed. Epervière*, Fr. *Habichtskraut*, G. (*Gray's Manual*, 237.) The rat-

tlesnake weed has a smooth slender flower-stem, one or two feet high, either naked or furnished with from one to three leaves, and dividing at top into a loose spreading corymb of yellow flowers. The plant is common, growing in dry places and open woods, in most of the eastern and northern parts of the United States and Canada. The leaves and root are thought to possess medical virtues, and, being deemed astringent, have been used in *hemorrhagic diseases*. The juice is supposed by some to have the power of removing *warts*. Dose of infusion (two ounces to the pint), a wineglassful.

HIPPURIC ACID ($C_9H_9NO_3$). *Benzoylglycocoll*, $CH_2<^{NH.C_7H_5O}_{COOH}$. This occurs in considerable amount in the urine of herbivorous animals, sometimes in that of man. Benzoic and cinnamic acids, toluol, and other aromatic substances, when taken internally, are eliminated as hippuric acid. It crystallizes in rhombic prisms, melting at 187° C., and at about 240° C. decomposes into benzoic acid, benznitrile, and prussic acid. Boiling acids or alkalies decompose it into benzoic acid and glycocoll. According to the experiments of Meissner and Shepard, hippuric acid injected into the blood of animals acts as a very decided poison, but the hippurates have been suggested by Dr. Garrod as a remedy in the *uric acid diathesis*. He affirms that if outside of the body the sodium hippurate be added to a blood-serum that shows the presence of a urate, the latter is soon removed. Sodium hippurate may be combined with lithium or potassium salts; the dose is ten grains (0·65 Gm.) three times a day.

HOANG-NAN. This is the bark of the *Strychnos Malaccensis*, Benth. (nat. ord. Loganiaceæ), or tropical *bindweed*, a climbing plant, which grows in Malacca and surrounding countries. Brucine and strychnine are stated to have been found in it (*Newer Mat. Med.*), brucine being the more abundant of the two. It has been found to produce in animals general tetanic spasms similar to those caused by strychnine. It probably has the same range of medicinal application as has nux vomica, although special virtues have been claimed for it in the treatment of *chronic skin diseases*. Dose of powdered bark, three grains (0·19 Gm.).

HOG-GUM. *Gum-Hogg. Kuteeragum.* Under the name of Gum-Hogg a peculiar gum is much used in marbling paper. A full discussion of it may be found in the 14th edition of the *U. S. Dispensatory*, but, as it appears to be only a variety of Bassora gum, we omit any further account of it.

HOLIGARNA LONGIFOLIA. Roxb. (Nat. ord. Anacardiaceæ.) According to David Hooper (*P. J. Tr.*, xxv. 1895), the black juice of this tree, which is used in India as the basis of a varnish, is actively vesicant, and contains a body closely allied to, if not identical with, cardol.

HOLOCAINE. *p-Diethoxyethenyl-diphenylamidine Hydrochloride.* $(OC_2H_5.C_6H_4.NH.C(CH_3):N.C_6H_4.OC_2H_5)HCl$. Formed by the union in molecular proportions of phenacetin and p-phenetidine with the elimination of water. The salt commonly used of this base is a hydrochloride which readily dissolves in boiling water, leaving on cooling a saturated solution containing about 2½ per cent. of the hydrochloride. This solution is slightly bitter, neutral in reaction, and keeps many months without change. In boiling, a porcelain vessel should always be used, as the solution at 212° C. attacks glass.

Holocaine has been brought forward as a local anæsthetic in the treatment of diseases of the eye. The anæsthesia, which is said to develop in from fifteen seconds to a minute after the instillation of the solution, lasts from ten to fifteen minutes. The amount of burning produced is about the same as with cocaine. The advantages which are claimed for it over the latter alkaloid are that it does not change the pupil, the accommodation, or the intraocular pressure, and is antiseptic. It does not contract the blood-vessels. The objections to it are that the instillation has to be renewed in from ten to fifteen minutes, and that it is about five times as toxic as is cocaine, so that it cannot be used hypodermically. According to the experiments of Heinz and Schlosser (*Klin. Monat. f. Augen.*, xxxv., 1897), the ½ of 1 per cent. solution affects bacteria, whilst the 1 per cent. solution is a powerful germicide, rapidly killing the lower organisms, including infusoria. Even in small doses it causes in frogs and in mammals violent convulsions which appear to be of cerebral origin, since after division of the spinal cord in the mouse the convulsions were confined to the anterior portion of the body. Holocaine is an active muscle poison, the 1 per cent. solution rapidly killing voluntary and cardiac muscles in the frog, and it exerts also a curare-like influence upon the motor nerves. According to Winselmann, its 1 per cent. solution exceeds in anæsthetic power the 3 per cent. solution of cocaine.

HOOCHINOO. This is an alcoholic drink which is clandestinely distilled by the Alaskan Indians, and has been supposed, on account of the frenzy which it produces in them, to contain some poisonous substance other than alcohol. Prof. John Marshall found it, however, to be simply an alcoholic liquor of about the strength of sherry.

HORDEUM. Several species of the graminaceous genus Hordeum are cultivated in different parts of the world. The most common are *H. vulgare*, L., and *H. distichon*, L., both of which have been introduced into the United States. The original country of the cultivated barley is unknown. The plant has been found growing wild in Sicily and in various parts of the interior of Asia. *H. vulgare* is said by Pursh to grow in some parts of the United States, apparently in a wild state. The fruits or grains are used in various forms.

1. In their natural state they are oval, oblong, pointed at one end, obtuse at the other, marked with a longitudinal furrow, of a yellowish color externally, white within, having a faint odor when in mass, and a mild sweetish taste. Careful analyses of barley have been made, which agree in the main, though differing in some details, especially as to whether any sugar exists in the barley before malting.

Pillitz found (*Zeit. für Anal. Chem.*, 1872) in the dry barley 14·3 per cent. of insoluble albuminates, 2·1 per cent. of soluble albuminates, 62·6 per cent. of starch, 1·9 per cent. of dextrin, 2·7 per cent. of sugar, 1·7 per cent. of extractive material, 3·1 per cent. of fat, 1·4 per cent. of soluble ash, 1·2 per cent. of insoluble ash, and 8·9 per cent. of lignin. The presence of sugar seems to have been shown by Kühnemann (*Deutsch. Chem. Ges.*, 1875 and 1876), who found a crystallized dextrogyrate sugar which did not reduce alkaline copper solution, and an amorphous lævogyrate mucilaginous substance called *sinistrin*. According to Kühnemann, barley does not contain dextrin.

Clifford Richardson (*Bulletin No. 9, Department of Agriculture*, 1886) gives the following as the average composition of American barley: water, 6·47 per cent.; ash, 2·87; oil, 2·67; sugar, etc., 7·02; dextrin and soluble starch, 3·55; starch, 62·09; albuminoids soluble in 80 per cent. alcohol, 3 66; albuminoids insoluble in 80 per cent. alcohol, 7·86; fibre, 3·81: total, 100·00. He finds, moreover, that on an average the grain makes up 84·78 per cent. and the hull 15·22 per cent. of the barley.

2. *Malt* consists of the seeds made to germinate by warmth and moisture, and then baked so as to deprive them of vitality. It is in the form of malt that barley is so largely consumed in the manufacture of malt liquors. (See *Maltum*, page 1716.) An interesting substance, called *diastase*, was discovered by MM. Payen and Persoz in the seeds of barley, oats, and wheat, and in the potato. It is found, however, only after germination, in which process the production of it appears to be the first step. Germinated barley seldom contains it in larger proportion than two parts in a thousand. It is obtained by bruising freshly germinated barley, adding about half its weight of water, expressing strongly, treating the viscid liquid thus obtained with sufficient alcohol to destroy its viscidity, then separating the coagulated albumen, and adding a fresh portion of alcohol, which precipitates the diastase in an impure state. To render it pure, it must be redissolved as often as three times in water, and precipitated by alcohol. For an account of the mode of preparing diastase from malt, recommended by M. Perrot, see the *Journal de Pharmacie*, Juillet, 1874, 43. It is solid, white, tasteless, soluble in water and weak alcohol, but insoluble in the latter fluid when concentrated. Though without action upon gum and sugar, it has the extraordinary property, when mixed, in the proportion of only 1 part to 2000, with starch suspended in water, and maintained at a temperature of about 71·1° C. (160° F.), of converting that principle into dextrin and *maltose*. This latter is a variety of sugar produced only by this action of malt. It was first recognized by Dubrunfaut, but has been more thoroughly studied by O'Sullivan and by Schulze. Its formula is $C_{12}H_{22}O_{11} + H_2O$; the molecule of water of crystallization it loses at from 100°–110° C. (or, as Richter proposes, it may have the formula $C_{18}H_{34}O_{17}$). O'Sullivan explains the action of diastase upon starch by the following reactions:

At 63° C.—$C_{18}H_{30}O_{15} + H_2O = C_{12}H_{22}O_{11} + C_6H_{10}O_5$.

At from 64°–70° C.—$2(C_{18}H_{30}O_{15}) + H_2O = C_{12}H_{22}O_{11} + 4(C_6H_{10}O_5)$.

At 70° C.—$4(C_{18}H_{30}O_{15}) + H_2O = C_{12}H_{22}O_{11} + 10(C_6H_{10}O_5)$. (*Chem. Soc. Journ.*, 10, 597.)

The crystals of maltose, $C_{12}H_{22}O_{11} + H_2O$, are soluble in water and alcohol, they reduce Fehling's solution, and, according to O'Sullivan, are equal to from 63·9–65·5 per cent. of dextrose, but, according to Schulze, they are equal to from 66–67 per cent. of dextrose, and show a specific rotatory power of $[a] = 150°$ to the right. The whole of the starch undergoes this change, except the teguments of the granules, amounting to about 4 parts in 1000. The change which barley undergoes during germination, and in malting, is of a similar character. The purity of diastase may be tested by mixing 0·05 part of it with 200 parts of paste containing 10 parts of starch; after standing, the resulting liquid should filter rapidly, and decolorize five times its volume of Fehling's solution. The name of *maltine* has been given to the diastase of malt; and this principle has been found identical with the salivary ferment in its action on alimentary substances. Indeed, according to M. Contara, the two ferments, vegetable and animal, appear to be identical, not only in the action referred to, but in their chemical and physical properties; and consequently there is but one diastase, whether vegetable or animal. (*Arch. Gén.*, Avril, 1870, 501.)

Besides the diastase a second soluble ferment is formed during the malting process, the so-called *peptase*, which in the mashing process changes the proteids of the malt into peptones and parapeptones, which give nutritive value to the beer obtained from malt. For a fuller account of the composition and functions of malt, see Sadtler's *Industrial Organic Chemistry*, 179 *et seq.*

3. *Hulled barley* is merely the grain deprived of its husk, which, according to Einhoff, amounts to 18·75 parts in the hundred.

4. *Barley meal* is formed by grinding the seeds, previously deprived of their husk. It has a grayish-white color, and contains, according to Fourcroy and Vauquelin, an oleaginous substance, sugar, starch, nitrogenous matter, acetic acid, calcium and magnesium phosphates, silica, and iron. It may be made into a coarse, heavy, hard bread, which in some countries is much used for food.

5. *Pearl barley* (*Hordeum decorticatum*, Br. 1885) is the seed deprived of all its investments and afterwards rounded and polished in a mill. It is in small round or oval grains, having the remains of the longitudinal furrow of the seeds, and of a pearly whiteness. It is wholly destitute of hordein, and abounds in starch, with some gluten, sugar, and gum. This is the proper form of barley for medicinal use.

Barley is one of the mildest and least irritating of farinaceous substances, and forms, by decoction with water, a mucilaginous drink much employed from the time of Hippocrates to the present. Pearl barley is the form usually preferred for the preparation of the decoction, made by pouring four pints of boiling water on two troyounces of pearl barley and boiling away to two pints, and straining. Malt affords a liquor more demulcent and nutritious, and the decoction of malt may be prepared by boiling from two to four ounces in a quart of water, and straining. When hops are added, the decoction takes the name of *wort*, and acquires tonic properties, which render it useful in debility.

HOUTTUYNIA CALIFORNICA. B. and H. (*Anemopsis Californica*, Hook. et Arn.) *Yerba Mansa.* The root of this piperaceous Californian plant is employed by the natives in *chronic malaria*, and also in *diarrhœa* and *dysentery*, and has been used with asserted good results in *gonorrhœa* and *rheumatism*. For elaborate histological study, see *Drug. Circular*, May, 1897. Dose of the fluid extract, from fifteen to sixty minims (0·924–3·69 C.c.).

HUAMANRIPA. This is a Chilian drug, the plant growing on the slope of the Cordilleras at considerable heights. Dr. Lapater found it to be stimulating, emetic, sialagogue, and diaphoretic. (*Western Druggist*, 1886, 410.)

HURA BRASILIENSIS. Willd. (Now *H. crepitans*, L.) *Assacou. Sablier*, Fr. *Sandbüchsenbaum*, G. This is a Brazilian tree belonging to the

family of Euphorbiaceæ. It is characterized by the tendency of its fruit when ripe to break with violence into several pieces, and thus scatter the seeds It has long been known as an acrid emetocathartic, capable in large doses of acting as a violent poison. The fresh juice, the seeds, and a decoction of the bark all have these properties, which, in fact, belong in a greater or less degree to most of the Euphorbiaceæ; and, as in other members of the same family, an oil expressed from the seeds is actively purgative. Martius states that the juice is anthelmintic, and employed to intoxicate fish. But attention has been especially attracted to the plant, in consequence of reports favorable to its efficacy in the *elephantiasis* or *leprosy* of Brazil. These reports were received by the Academy of Medicine, of Paris, from the French consul in one of the towns of Pará. Experiments have been made by the Brazilian physicians, and it is said with favorable results. The fact is that various acrid emeto-cathartic medicines, capable also of producing diaphoresis, have been more or less useful in *elephantiasis*, as the *Calotropis gigantea*, Dryand. (nat. ord. Asclepiadaceæ), and one or more species of Ionidium (nat. ord. Violaceæ), and it is probable that the assacou acts in a similar manner, and with similar results. The milky juice of the plant, and an infusion or decoction of the bark, are used. The juice is extremely acrid, producing on the skin, when applied to it, an erysipelatous redness and a pustular eruption; the natives are said to employ it in the preparation of a poison. A grain of the juice made into a pill, or a scruple of the bark infused in a pint of water, is given every day, and gradually increased as the stomach and bowels will bear it. Every week an emetic preparation is administered, made by boiling half an ounce of the bark in a pint of water to half a pint, to which twelve drops of the juice are added. Every second or third day the patient takes a bath consisting of a saturated infusion of the bark. (*Journ. de Pharm.*, xiv. 424.)

HYÆNANCHE GLOBOSA. Lamb. (Now *Toxicodendron Capense*. Thunb.) (Nat. ord. Euphorbiaceæ.) The fruits of this South African species are said to be used for the poisoning of hyenas. They have been investigated by Arthur Baron von Engelhardt (*Kobert's Arbeiten*, 1892), who finds in them a chemically neutral, bitter principle, *hyananchine*, which is a powerful poison, resembling in its physiological action strychnine; from which, however, it differs in that it powerfully affects the cerebrum. The convulsions which it produces are of central origin, the poison having no action upon the nerve-trunks or the muscles.

HYDRACETIN. *Pyrodine.* The hydracetin of commerce is stated to be a varying compound, whose active principle is *acetylphenylhydrazin* ($C_6H_5NH\text{-}NH.C_2H_3O$). It is soluble in alcohol and in water in proportion of 1 to 50. According to Guttmann (*Pharm. Centralh.*, May 16, 1889, 311), hydracetin is a powerful antipyretic and antirheumatic remedy. It occurs as a white, odorless, almost tasteless crystalline powder, melting at from 128°–129° C. (262·4°–264·2° F.), and has been given in doses of three-quarters of a grain (0·049 Gm.) two or three times a day. It is stated that it cannot be continuously used without danger. Externally, hydracetin is used in place of chrysarobin in *psoriasis* and similar disorders, in an ointment of from 5 to 15 per cent.

HYDRANGEA ARBORESCENS. L. *Common Hydrangea. Seven Barks.* (Nat. ord. Saxifragaceæ.) The root of our indigenous Hydrangea, which is the part used, consists of a caudex, from which proceed numerous radicles, from the thickness of a quill to that of a finger or more. For use it should be cut into transverse pieces when fresh, and then dried. The taste is aromatic, pungent, and not unpleasant. Bondurant (*A. J. P.*, 1887, 122) has isolated a characteristic glucoside, *hydrangin*, crystallizing in stellate clusters, melting at 235° C., and subliming without decomposition. It is decomposed by dilute acids into a resin-like body and glucose. Its aqueous solution fluoresces strongly on addition of an alkali, resembling æsculin, but distinctly different in several particulars. He also obtained a fixed oil and a volatile oil, the latter containing sulphur. Two resins seemed also to be present, together with saponin and sugar. He found no tannin, however. Its decoction is said to have been used with great advantage among the Cherokee Indians, and subsequently by settlers, in *calculous complaints*. (See *New Jersey Med. Reporter*, 1850, 1854, and 1885.) In overdoses it occasions vertigo, oppression of the chest, etc.

HYDRARGYRI SULPHURETUM NIGRUM. *Black Sulphide of Mercury. Mercurous Sulphide. Ethiops Mineral.* This now disused remedy was prepared as follows: "Take of Mercury, Sulphur, each, *a pound*. Rub them together till all the globules disappear." *U. S.*, 1850. For properties, see *U. S. D.*, 14th ed., 1259.

HYDRARGYROL. $(C_6H_4.OH.SO_3)_2Hg$. *Mercury Paraphenylthionate.* This salt occurs in brownish-red scales, having a gingerbread-like odor, neutral reaction, and sp. gr. 1·85. It dissolves in water and glycerin, with a ruby-red color. It is said to contain over 53 per cent. of quicksilver, and not to precipitate albumen. It has been proposed by Gautrelet as a substitute for corrosive sublimate in antiseptic surgery. A solution of 4 to 1000 is not irritant to the mucous membrane or skin, but very active as an antiseptic, sterilizing bouillons at once. When taken in large doses it is toxic, thirty and a half grammes of it having caused death; but, according to its introducer, as a poison it is seventy-five times less active than is corrosive sublimate.

HYDRIODIC ACID, DILUTE. *Acidum Hydriodicum Dilutum.* This preparation was introduced into the U. S. Pharmacopœia in 1860 and dismissed in 1870. Owing to the difficulty of preserving it from change, it has been supplanted by the official syrup. (See *Syrupus Acidi Hydriodici*, PART I.) The official formula in 1860 was as follows. "Take of Iodine, in fine powder, *a troy-ounce;* Distilled Water, *a sufficient quantity*. Mix thirty grains of Iodine with five fluidounces of Distilled Water in a tall glass-stoppered bottle, having the capacity of half a pint, and pass into the mixture hydrosulphuric acid gas until the color of the Iodine entirely disappears, and a turbid liquid remains. Detach the bottle from the apparatus employed for introducing the gas, and gradually add the remainder of the Iodine, stirring at the same time. Then reattach the bottle, and again pass the gas until the liquid becomes colorless. Decant the liquid into a small matrass which it is nearly sufficient to fill, boil it until it ceases to emit the odor of hydrosulphuric acid, and filter through paper. Then pass sufficient Distilled

Water through the filter to bring the filtered liquid to the measure of six fluidounces. Lastly, keep the liquid in a well-stopped bottle. The hydrosulphuric acid gas, required in this process, may be obtained by mixing, in a suitable apparatus, *a troyounce and a half* of sulphide of iron, *two troyounces* of sulphuric acid, and *six fluidounces* of water." *U. S.*

The rationale of the process is extremely simple. The hydrogen of the hydrogen sulphide unites with the iodine to form hydriodic acid whilst the sulphur is deposited, $2H_2S + 2I_2 = 4HI + S_2$. It is well to agitate the vessel slightly soon after the hydrogen sulphide is passed into the liquid, so that the excess of iodine may be taken up by the solution of hydriodic acid, iodine being quite soluble even in a dilute solution. Some difficulty may be experienced if this is not done, through the finely precipitated sulphur coating the iodine and preventing its easy conversion. We have found it an improvement to dissolve the iodine in just sufficient alcohol, and then add to the water; the greater part is thrown down as a fine precipitate which is much more easily acted on by the hydrogen sulphide.*

The iodine is known to have been all combined by the disappearance of the color. An excess of hydrogen sulphide is of no disservice, as it is driven off by the boiling. By filtration the liberated sulphur is separated, and the clear diluted hydriodic acid remains. By taking fixed proportions of iodine and water, an acid of the desired strength is secured.

In its pure state hydriodic acid is in the form of a gas, which fumes in the air, is colorless, and has an odor not unlike that of hydrochloric acid. It has a strong affinity for water, which, when saturated with it, forms liquid hydriodic acid. This has the sp. gr. 1·7, boils at 127° C. (260° F.), and may be distilled.

The diluted acid, as prepared by the former U. S. process, is colorless when recently prepared, of a sour taste, and of the sp. gr. 1·112. The acid is precipitated yellowish white by test-solution of silver nitrate, and this precipitate is not perceptibly dissolved either by nitric acid or ammonia. When exposed to the air it gradually darkens, in consequence of the separation of iodine, of which it acquires the characteristic odor. It is more rapidly decomposed, with the same result, by chlorine, by nitric, sulphuric, iodic, and sulphurous acids, and by ferrous sulphate. Mr. John A. Dunn has found that this change is prevented by the addition of one-third of a grain of crystallized sodium hyposulphite to a fluidounce. (*A. J. P.*, 1869, 42.)

Medical Properties and Uses. Diluted hydriodic acid was introduced into use as a medicine by Dr. Andrew Buchanan, of Glasgow. The acid official in 1860 contains ten grains of iodine in each fluidrachm, and is therefore twice as strong as Dr. Buchanan's solution. There can be little doubt that hydriodic acid is capable of producing the alterative effects of iodine; and it may be given in all cases to which that medicine is applicable. The dose may be half a fluidrachm (1·9 C.c.) three times a day, diluted with water. When the solution becomes discolored it may be irritant through the liberated iodine; but this effect may be obviated by exhibiting it in any amylaceous liquid, as barley-water.

HYDROCHINONE. *Hydroquinone.* $C_6H_4(OH)_2$. This is one of the three isomeric diatomic phenols, being *paradioxybenzene.* It was first prepared by the dry distillation of quinic acid, but is now made from quinone by reduction with sulphurous acid, the quinone being made by oxidizing aniline with bichromate mixture ($K_2Cr_2O_7 + H_2SO_4$). It is in shining white leaflets melting at 169° C., soluble in water, alcohol, and ether, and is used largely in photography as a developing agent. In 1877 Brieger found that hydroquinone produces in man giddiness, tinnitus aurium, and a lessening of the force and frequency of the pulse. The experiments of Dr. P. J. Martin have shown that in the frog the hydroquinone causes violent convulsions, followed by paralysis and death through failure of the respiration, due to an action upon the spinal cord. In the mammal small doses produce a rise in the arterial pressure, followed by a depression; both these phenomena are apparently the result of an action of the drug upon the arterial vaso-motor system, although it is probable, from the experiments of Beyer, that the toxic dose of hydroquinone paralyzes both the heart-muscles and the muscle-fibres in the coats of the arterioles. The bodily temperature is lowered by large doses of hydroquinone, and, according to the experiments of Martin, this is chiefly due to an increase of heat-dissipation, and is, therefore, probably the result of a vaso-motor paralysis.

Hydroquinone is also a distinct antiseptic, but, according to Dr. Antaeff, when it is mixed with a solution of urea the latter principle undergoes rapid decomposition. The influence of hydroquinone upon the human being has been especially studied by Silvestrini and Picchini, and by Dr. Gaetano Traversa. (*La France Méd*, May, 1890.) According to these authorities, it is a prompt antipyretic, producing, in dose of from three to eleven grains (0·19–0·71 Gm), depression of temperature in fever, the reduction beginning in half an hour, and reaching its maximum in an hour and a half. Usually the antipyretic action is not accompanied by disagreeable symptoms, although after the larger dose excessive sweating, chills, and some nervous disturbances have been noted. It was found in the experiments of Martin that the fall of temperature is due to an increase of heat-dissipation; this is confirmed by the observation of Traversa, that the peripheral temperature may rise as much as two degrees, although the internal temperature is de-

* Various processes have been proposed for making hydriodic acid. Dr. Buchanan used an extemporaneous formula, which consisted in dissolving 330 grains of potassium iodide and 264 of tartaric acid, each in one and a half fluidounces of water, mixing the solutions, filtering to separate the potassium bitartrate formed, and finally adding sufficient distilled water to make the solution measure fifty fluidrachms. Each fluidrachm of this preparation contained five grains of iodine. Beginning with a few drops, he gradually increased to a fluidrachm, and finally even half a fluidounce or a fluidounce three times a day. Mr. John A. Dunn's modification of Buchanan's process is as follows. Take of potassium iodide 209¾ grains; tartaric acid, in crystals, 190¼ grains. Dissolve the iodide in three fluidrachms of distilled water, and the acid in the same quantity, and filter if necessary; mix the solutions, set the mixture in ice-cold water, and allow it to stand for one hour; then filter, and make up the measure to two fluidounces. Each fluidrachm represents 10 grains of iodine. (*A. J. P.*, 1869, 41.) Prof. H. Kolbe (*Journ. f. prakt. Chem.*, 1879, 172, and *A. J. P.*, June, 1877) adds phosphorus to iodine in a retort filled with carbonic acid gas. Heat is applied, and water added; on application of moderate heat, hydriodic acid gas free from iodine is produced. C. Winckler (*A. J. P.*, May, 1880; from *Jahresber. d. Phys. Ver.*) dissolves iodine in carbon disulphide; adds sufficient water to form a layer on top of the solution of iodine; passes a stream of hydrogen sulphide through the mixture; when this has acquired a yellow color, the layers are separated, the aqueous hydriodic acid is boiled a few minutes to expel hydrogen sulphide, and it is then chemically pure.

pressed. The excretion of urea is said to be diminished. Hydroquinone has been used with asserted good results in *infectious fevers*, and in *acute articular rheumatism;* also as a gastro-intestinal disinfectant. According to Forster, a 1 per cent. solution will arrest putrefaction and alcoholic fermentation.

HYDROCOTYLE ASIATICA. L. *Thick-leaved Pennywort.* (*Bevilacqua.* Boileau.) *Indian Pennywort. Bevilacqua*, Fr. *Wassernabel*, G. This is a small umbelliferous plant, growing in Southern Africa and in India, where it has long been used as an alterative. M. Jules Lépine discovered in it a peculiar oleaginous substance, *vellarine*, having a strong odor recalling that of the plant, and a bitter, pungent, and persistent taste. (*Journ. de Pharm.*, 1885, 49.) It is said to be diuretic, and has been given in *fever* and *bowel complaints;* also in *syphilitic* and *scrofulous affections.* (*P. J. Tr.*, 1860.)

Dr. C. Daruty de Grandpré (*Les nouv. Remèdes*, April 8, 1888) finds that in small doses it is an energetic stimulant, and that in large doses it is narcotic, producing stupor, headache, and in some persons vertigo with a tendency to coma.

HYDROCYANIC ETHER. *Cyanide of Ethyl. Propionitrile.* C_3H_5N, or $C_2H_5.CN$. This ether was discovered by Pelouze. It is formed by distilling a mixture of barium sulphovinate and potassium cyanide, or, better, by the action of ethyl iodide on potassium cyanide in closed tubes at a temperature of 180° C. It is a colorless liquid, of an agreeable ethereal odor, soluble in alcohol, ether, and water, boiling at 98° C. (208·4° F.), and having the sp. gr. 0·78. *Ethyl cyanide* is very poisonous, but less so than hydrocyanic acid, with which it agrees in therapeutic action and dose.

HYDROGEN SULPHIDE. *Sulphuretted Hydrogen. Hydrosulphuric Acid.* H_2S. A colorless gas of unpleasant odor, soluble in water, to which it imparts an acid reaction. 3·23 volumes of gas are absorbed by one volume of water at 15° C. Also soluble in alcohol. Has been liquefied at ordinary temperatures under a pressure of 17 atmospheres, or at ordinary pressures by a cold of —74° C. (—101·2° F.), and at —85° C. (—121° F.) becomes an ice-like solid.

The symptoms of poisoning by hydrogen sulphide vary with the amount taken. Its inhalation in a concentrated form is followed by giddiness, nausea, excessive weakness, and rapid or immediate loss of consciousness. The very diluted gas produces nausea, pain in the head, and great general weakness; followed, if sufficient be taken, by coma, or stupor with delirium, and in some cases by general convulsions. The blood becomes of a brownish-black color, and after death remains fluid. The general appearances at the autopsy are not to be distinguished from those produced by the absorption of carbonic acid gas, but the diagnosis is readily made by the odor which pervades the whole corpse.

Dr. Bruère (*Journ. Anat. and Physiol.*, Oct. 1891) finds that bright red diluted blood, under the influence of the sulphide, becomes of an olive-green color, and that out of the oxyhæmoglobin a new compound is formed, *sulphmethæmoglobin* or *sulphhæmoglobin*, probably by a union of hydrogen sulphide with hæmatin. It has been shown by Dr. Paul Binet (*Rev. Méd de la Suisse Rom.*, xvi., 1896) that this sulpho-methæmoglobin is produced in the blood during life, especially when the gas is in very large amount. It is worthy of remark that Dr. Bruère found the *hydrogen selenide* and the *hydrogen telluride* to act the same as the hydrogen sulphide.

In 1886 Dr. Bergeon proposed to the French Academy a method of treating tuberculosis by injecting hydrogen sulphide, diluted with pure carbonic acid, into the large intestine, the method being founded upon the supposed power of hydrogen sulphide to destroy the tubercular bacillus. The method of Bergeon had an extraordinary run, and then fell rapidly into desuetude, but there can be no doubt that the hydrogen sulphide has a distinct influence upon mucous membranes. It is a useful remedy in *pulmonary catarrh*, chronic or acute, as well as in *chronic rheumatism* and in *gout.* It is for this reason that sulphur springs are so frequently resorted to. Water saturated with hydrogen sulphide and carbonic acid gas is usually not objected to by patients after the first day or two of its taking, and does not disagree with the stomach. The dose is from two to four ounces, three or four times a day.

HYDROXYLAMINE HYDROCHLORIDE. $NH_2.OH.HCl$. The free base is known only in solution, and is unstable. The crystalline hydrochloride forms colorless hygroscopic crystals similar to ammonium chloride in appearance, soluble in an equal weight of water, also in glycerin and in fifteen parts of alcohol. In 1888 Prof. Binz found that this substance caused in the lower animals stupor, convulsions, and a destruction of the red blood-corpuscles, of such character that their hæmoglobin was reduced to methæmoglobin or even to hæmatin. In 1889 Prof. L. Lewin, of Berlin, further investigated the subject, confirming in part the results obtained by Prof. Binz, and showing that the poison acts both upon the dead and living blood, and that its action upon the corpuscle is probably due to its decomposition, and the liberation of nitric or nitrous acid. In 1889 Dr. John Fabry (*Arch. de Derm. et de Syph.*, tome ii., 1889) found that a 10 per cent. solution is exceedingly irritating to most human skins, producing intense redness, violent burning, sweating, and not rarely vesication. Some skins will not bear a 1 per cent. solution, so that it is not safe in a new case to use a solution stronger than this. The substance was employed by Fabry, and since then by other clinicians, as an agent to replace pyrogallic acid and chrysarobin in the treatment of skin diseases, whilst it would offer the advantage of being colorless, and not staining skin, linen, etc. It has been used in *chronic psoriasis*, in *scabies*, in *lupus*, *herpes tonsurans*, *parasitic sycosis*, etc., with asserted excellent results, though Groddeck condemns it as being too irritating and liable to produce constitutional symptoms, and inferior in its healing powers to chrysarobin and pyrogallic acid. The solution may be prepared with alcohol or water, but should always be rubbed up with prepared chalk to neutralize any excess of acid.

HYGROL. A name applied to colloidal mercury, or mercury in a fine state of division. It occurs as a nearly black powder, slightly soluble in water, insoluble in alcohol and ether. It has been proposed as a substitute for mercury in mercurial ointment.

HYGROPHILA SPINOSA. T. Anders. (Nat. ord. Acanthaceæ.) This is an Indian plant, the seeds of which are considered aphrodisiac and diuretic. (See Jayesingha, *Brit. Med. Journ.*, vol. ii., 1887.)

HYPAPHORUS SUBUMBRANS. Hasskl. (Now *Erythrina lithosperma.* Blume.) From the seeds of this leguminous tree, largely grown for shade in the coffee gardens of Java, P. C. Plugge has obtained *hypaphorine*, a tetanizing alkaloid. (*Arch. f. Exp. Path. und Pharm.*, xxxii.)

HYPERICUM PERFORATUM. L. *St. John's Wort. Millepertuis, Casse-diable*, Fr. *Johanniskraut, Harthen*, G. (Nat. ord. Hypericaceæ.) A perennial herb, abundant both in Europe and in this country. It is usually from one to two feet high, with leaves which, from the presence of numerous transparent vesicles, appear as if perforated, and have hence given origin to the botanical designation of the plant. The flowers are numerous and of a deep yellow color. The flowering summits are the parts used. St. John's wort has a peculiar balsamic odor, which is rendered more sensible by rubbing or bruising the plant. Its taste is bitter, resinous, and somewhat astringent. It imparts a yellow color to cold water, and reddens alcohol and the fixed oils. Its chief constituents are volatile oil, a resinous substance, tannin, and coloring matter. This latter, known as *hypericum red*, is a reddish resin, smelling like the flowers, soluble in alcohol, ether, ethereal and hot fatty oils, coloring the solution from wine red to blood red. It is soluble in alkalies with green color, and gives yellow precipitates with the alkaline earths and metallic salts. As a medicine it was in high repute among the ancients and the earlier modern physicians. Among the complaints for which it was used were *hysteria, mania, intermittent fever, dysentery, gravel, hemorrhages, pectoral complaints, worms*, and *jaundice;* but it was, perhaps, most highly esteemed as a remedy in *wounds* and *bruises*, for which it was employed both internally and externally. It probably has somewhat analogous power to the turpentines. It formerly enjoyed great reputation for the cure of demoniacs, and the superstition still lingers among the vulgar in some countries. At present the plant is scarcely used except as a domestic remedy. The summits were given in the dose of two drachms or more. A preparation, *oleum hyperici* or *red oil*, made by macerating four ounces of the tops in a pint of olive oil, is still used in many families for bruises.

HYRACEUM. This is the product of *Hyrax Capensis*, an animal of South Africa, about the size of a large rabbit. It is said to be collected in small pieces on the rugged sides of mountains, and is probably the excrement or the dried urine of the animal. It is rather hard, tenacious, of a blackish-brown color, and in taste and smell not unlike castor. It is inflammable, and yields portions of its constituents to water and alcohol. It contains vegetable tissues, animal hair, sand, and globular particles, either resinous or oily. Schrader has found in it stearin, a gum-resin soluble in absolute alcohol, an odorous yellow substance soluble in ordinary alcohol and in water, a brown substance soluble in water, and insoluble residue. (See *A. J. P.*, 1879, 363.) Dr. Pereira considered it worthless as a therapeutic agent, though in physiological effects it is said to resemble American castor. (*P. J. Tr.*, x. 123.) For an elaborate paper on this substance by M. J. Léon Soubeiran, see *Journ. de Pharm.*, xxix. 378. E. D. Cope states that a similar substance is found in fissures of the rocks in New Mexico, and is probably a fecal and renal deposit of the wild rat, *Neotoma.*

HYSSOPUS OFFICINALIS. L. *Hyssop. Hysope*, Fr. *Isop, Ysop*, G. This is a European labiate plant, perennial, with numerous erect, quadrangular, somewhat branching stems, which are woody in their interior portion, about two feet high, and furnished with opposite, sessile, lanceolate-linear, pointed, punctate leaves. The flowers are violet-colored or blue, sometimes white, turned chiefly to one side, and arranged in half verticillated, terminal leafy spikes. The upper lip of the corolla is roundish and notched at the apex, the lower is divided into three segments, of which the undermost is obovate. The flowering summits and leaves are the parts used. They have an agreeable aromatic odor, and a warm, pungent, bitterish taste, due to the presence of a volatile oil. This oil is colorless or greenish yellow, of peculiar odor, sharp camphor-like taste, and neutral reaction. It has a sp. gr. from 0·88 to 0·98, distils between 142° and 162° C., and is soluble in its own bulk of alcohol of 0·85 sp. gr. According to Stenhouse, it is a mixture of several oxygenated oils. Hyssop is a warm, gently stimulant aromatic, applicable to the same cases as the other labiate plants. Its infusion has been much employed in *chronic catarrhs*, especially in old or debilitated people.

IBERIS AMARA. L. *Bitter Candytuft.* A small European herbaceous cruciferous plant. The leaves, stem, and root are said to possess medicinal properties; but the seeds are the most efficacious. The plant appears to have been employed by the ancients in *rheumatism, gout*, and other diseases. In large doses it is said to produce giddiness, nausea, and diarrhœa, and to be useful in *cardiac hypertrophy, asthma*, and *bronchitis*, in doses of from one to three grains (0·06–0·19 Gm.) of the seed. (*Prov. Med. and Surg. Journ.*)

ICHTHYOL. *Ammonium Ichthyol Sulphonate.* $C_{28}H_{36}S_3O_6(NH_4)_2$. In the dry distillation of a bituminous mineral containing fossil fish a tarry product is obtained. On treating this with sulphuric acid, and subsequently neutralizing with sodium or ammonium carbonate, ichthyol is procured. This is a red-brown syrupy liquid, of a bituminous odor and taste, puffing up considerably and carbonizing when heated, and upon continued incineration volatilizing without residue. Water, or a mixture of equal volumes of alcohol and ether, dissolves it to form a clear red-brown liquid of a faintly acid reaction. Pure alcohol or ether dissolves it only partially; petroleum benzin takes up only a small quantity. Upon the addition of hydrochloric acid to the aqueous solution a dark resinous mass is precipitated, which when separated is soluble in ether and in water, but is again thrown out from the latter solution by hydrochloric acid or sodium chloride. Treated with potash solution, ichthyol develops an odor of ammonia, and the mixture dried and burnt yields an hepatic coal, which with hydrochloric acid gives off hydrogen sulphide. The ammonium ichthyolate loses upon drying in a water-bath at least half its weight. The sodium ichthyol is a dark tar-like substance of an alkaline reaction, perfectly soluble in water. The ichthyol sulphonates of lithium, zinc, and mercury have also been prepared. Both preparations combine with fat and vaseline in all proportions, and are very rich in sulphur, containing, it is said, 10 per cent. According to Baumann, they have a great affinity for oxygen, and are powerful reducing agents.

Odorless ichthyol has been made by treating ichthyol with hydrogen dioxide. It is questionable,

however, whether the removal of the odorous constituents does not impair the therapeutic activity of the ichthyol.

Medical Properties. So far as is known, ichthyol has little or no general action, although it has been used to some extent internally in *rheumatism* and by Unna in *lepra*. As a liquid external remedy it has been most extravagantly praised by various German and American clinicians. Applied in the pure form to the sound skin, it produces irritation and burning. Peculiar alterative properties are attributed to it, and also the power of penetrating through the skin, so that it has been used with alleged extraordinary success as a local alterative and anodyne discutient in *chronic eczema*, *chronic urticaria*, *acne*, *intertrigo*, *lupus*, and *lepra* and various *ulcerations of the skin*, in *lymphatic enlargements*, for the softening and dispersion of *lipomas*, in *burns*, *frost-bites*, *sprains* and *contusions*, and in almost every form of *subacute* or *chronic gout* or *rheumatism*. When the skin is not destroyed or greatly inflamed the application should be made of the full strength or as a 50 per cent. ointment. In the various skin diseases or ulcerations the strength of the lotion or ointment may vary from 1 to 50 per cent. For internal administration, H. Wyatt (*P. J. Tr.*, xxi., 1891, 929) recommends the evaporation of the ichthyol on a water-bath and the formation of the residue into pills. He also made a good combination by adding 15 grains of magnesia (made into a milk with 90 minims of water) to 120 grains of ichthyol and evaporating over a water-bath to a pilular consistence. Dr. Latteux has found ichthyol to be an active germicide. (*Journ. de Méd.*, Paris, April, 1892.)

ICHTHYOL ALBUMINATE. *Ichthalbin.* This is a greenish-brown powder, insoluble in water and acid solutions, soluble in alkaline solutions, odorless, almost tasteless. It is prepared by precipitating fresh albumen with ichthyol and prolonged washing of the precipitate until the ichthyol odor and taste are removed. It is stated to contain about 75 per cent. of ichthyol. It is not toxic, and when given internally, even in large doses, produces little or no irritation of the gastro-intestinal tract. It is affirmed that as an internal remedy it is practically ichthyol, and as such is useful in various conditions connected with wide-spread vascular dilatation, in *syphilis*, in *struma*, and in other states of lowered nutrition. Dose, from fifteen to thirty grains (0·9–1·9 Gm.), three times a day, best taken in capsules; or in the case of young children mixed with chocolate.

IGNATIA. *U. S.* 1880. *Bean of Saint Ignatius. Semen Ignatiæ*, *Faba Ignatii*, *Faba Sancti Ignatii*, Lat. *Fève igasurique*, *Fève de Saint Ignace*, Fr. *Ignatiusbohne*, *Bittere Fiebernuss*, *Ignazbohnen*, G. *Fava di Santo Ignazio*, It. *Haba de Santo Ignacio*, Sp. *Strychnos Ignatii*, Berg., *Ignatia amara*, Linn., is a tree of the nat. ord. Loganiaceæ, of middling size, with numerous long, cylindrical, glabrous, vine-like branches, which bear opposite, nearly sessile, oval, pointed, entire, and very smooth leaves. The flowers are long, nodding, white, tubular, fragrant, and arranged in short, axillary racemes. The fruit is of the size and shape of a pear, with a smooth, whitish, ligneous rind, enclosing about twenty seeds, embedded in a dry medullary matter, and lying one upon the other. The seeds are the part used. The tree is a native of the Philippine Islands, where the seeds were highly esteemed as a medicine, and, having attracted the attention of the Jesuits, were honored with the name of their founder. Prof. Flückiger and Arthur Meyer have found that the seed has a close structural analogy to nux vomica. (*P. J. Tr.*, 1881, 1.)

The seeds are about an inch long, rather less in breadth, still less in thickness, convex on one side, obscurely angular, with two, three, or four faces on the other, and marked at one end with a small depression indicating their point of attachment. They are externally of a pale brown color, apparently smooth, but covered in fact with a short down or efflorescence, which may be removed by scraping them with a knife. They are somewhat translucent, and their substance is very hard and horny. They have no smell, but an excessively bitter taste. They were officially described as "about an inch and a fifth (3 Cm.) long, oblong or ovate, irregularly angular, dull brownish or blackish, very hard, horny; fracture granular, irregular; the albumen somewhat translucent, enclosing an irregular cavity with an oblong embryo; inodorous; very bitter." *U. S.* To Pelletier and Caventou they yielded the same constituents as nux vomica, and, among them, 1·2 per cent. of strychnine and 0·5 per cent. of brucine. J. M. Caldwell found strychnine and brucine, combined with igasuric acid, a volatile principle, extractive, gum, resin, coloring matter, fixed oil, and bassorin, but no starch or albumen. (*A. J. P.*, 1857, 298.) Flückiger, on the other hand, found 1·78 per cent. of nitrogen, corresponding to about 10 per cent. of albuminoid matter. (*Pharmacographia*, 443.) In consequence of the relatively larger proportion of strychnine which they yield, they have been used instead of nux vomica, in the preparation of that alkaloid, when their cost would permit of the substitution, but the nux vomica bean has been imported in such large quantities, and is now so low in price, that the ignatia bean is rarely used. The medical uses are those of nux vomica.

Abstractum Ignatiæ. *U. S.* 1880. *Abstract of Ignatia.* "Ignatia, in No. 60 powder, *two hundred parts* [or four ounces av.]; Sugar of Milk, recently dried and in fine powder, Alcohol, Water, each, *a sufficient quantity*, To make *one hundred parts* [or two ounces av.]. Mix Alcohol and Water in the proportion of *eight parts* [or six fluidounces] of Alcohol to *one part* [or five fluidrachms] of Water, and, having moistened the Ignatia with *one hundred parts* [or two fluidounces] of the menstruum, pack firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, until the Ignatia is exhausted. Reserve the first *one hundred and seventy parts* [three and one-half fluidounces] of the percolate, distil off the alcohol from the remainder, and mix the residue with the reserved portion. Place the mixture in an evaporating dish, and, having added *fifty parts* [or one ounce av.] of Sugar of Milk, cover it with a piece of thin muslin gauze, and set aside in a warm place where the temperature will not rise above 50° C. (122° F.), until the mixture is dry. Lastly, having added enough Sugar of Milk to make the mixture weigh *one hundred parts* [two ounces av.], reduce it to a fine, uniform powder.

Preserve the powder in a well-stopped bottle." The yield of extract is usually about 10 per cent. The dose of abstract is from one-half to one and a half grains (0·03–0·10 Gm.).

TINCTURA IGNATIÆ. *U. S.* 1880. *Tincture of Ignatia. Teinture de Fève de Saint Ignace*, Fr. *Ignazbohnentinktur*, G. "Ignatia, in No. 60 powder, *ten parts* [or eight ounces av.]; Alcohol, Water, each, *a sufficient quantity*. Mix Alcohol and Water, in the proportion of *eight parts* [or four and a half pints] of Alcohol to *one part* [or half a pint] of Water. Moisten the powder with *ten parts* [or half a pint] of the menstruum, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour menstruum upon it, until the Ignatia is exhausted. Reserve the first *ninety parts* [or four and a half pints] of the percolate, evaporate the remainder to *ten parts* [or half a pint], and mix with the reserved portion. Of this Tincture take any convenient number of parts, and, by means of a water-bath, evaporate it to dryness. Weigh the resulting extract, and from its weight calculate the quantity of extract contained in the one hundred parts of Tincture obtained, then dissolve the dried extract in the remainder of the Tincture, and add enough of the above menstruum to make the product weigh so many parts that each *one hundred parts* of Tincture shall contain *one part* of dry extract. Lastly, mix thoroughly, and filter through paper. Tincture of Ignatia thus prepared represents about *ten parts* of Ignatia in *one hundred parts*." Dose, from fifteen to twenty minims (0·9–1·25 C.c.). A tincture equivalent to the official preparation may be made by dissolving sixty grains of dry alcoholic extract of ignatia in a mixture of fourteen fluidounces of alcohol and one and a half fluidounces of water.

ILEX. *Holly. Houx*, Fr. *Stechpalme, Christdorn*, G. Several species of Ilex (nat. ord. Ilicaceæ) are employed in different parts of the world. The *I. aquifolium*, L., or *common European Holly*, is usually a shrub, but in some places attains the magnitude of a middling-sized tree. The viscid substance called *birdlime* is prepared from the inner bark. The leaves, which are of a bitter, somewhat austere taste, were formerly much esteemed as a diaphoretic, and in the form of infusion were employed in *catarrh, pleurisy, small-pox, gout*, etc. A few years since they gained a brief reputation in France as a cure for *intermittents*. They were used in powder, in the dose of a drachm two hours before the paroxysm; and this dose was sometimes repeated frequently during the apyrexia. Their febrifuge virtues are said to depend on a bitter principle, *ilicin*. M. Labourdais obtained this principle by boiling a filtered decoction of holly leaves with animal charcoal, allowing the charcoal to subside, washing it, then treating it with alcohol, filtering off the alcoholic solution, and evaporating it to a syrupy consistence. The liquid thus obtained was very bitter, and, on being allowed to evaporate spontaneously, yielded an amorphous substance, having the appearance of gelatin, which was the principle in question. (See *A. J. P.*, xxi. 89.) A yellow coloring substance called *ilexanthin*, and a peculiar acid called *ilicic acid*, have been obtained by Dr. F. Moldenhauer. Ilexanthin is obtained in the following manner. The leaves are exhausted with alcohol, the alcohol is distilled off, and the residue set aside for several days. A sediment forms, which is separated from the mother-liquor, treated with ether to remove the chlorophyll, and then purified by repeated solution in alcohol and crystallization. The composition of ilexanthin is $C_{17}H_{22}O_{11}$. It crystallizes in yellow needles, which change color at 185° C. (365° F.), melt at 198° C. (388° F.), and at 214° C. (417° F.) boil with decomposition, and are not sublimable. It is insoluble in ether, but soluble in alcohol. In cold water it is almost insoluble; but hot water dissolves it freely, and deposits it in crystals on cooling. (*Chem. Centralblatt*, 1857, 766.) The *berries* are about the size of a pea, red and bitter, and are said to be purgative, emetic, and diuretic. Ten or twelve of them will usually act on the bowels, and sometimes vomit. Their expressed juice has been used in *jaundice*.

The *Ilex opaca*, Soland. in *Ait. Hort. Kew.*, or *American holly*, is a middling-sized evergreen tree, growing throughout the Atlantic section of the United States, and especially abundant in New Jersey. It is so similar to the European plant that it is by some writers considered as the same species. The berries, examined by Mr. D. P. Pancoast, were found to contain tannin, pectin, two crystallizable organic principles, and salts of potassa, lime, and magnesia. One of the crystallizable principles was inodorous and tasteless, the other inodorous but intensely bitter. The latter was obtained by a treatment similar to that of M. Labourdais, above described; but, after the evaporation of the tincture to a syrupy consistence, the process was continued by adding potassium carbonate and afterwards ether, and agitating briskly. The ethereal solution, rising to the surface on repose, was separated, and allowed to evaporate spontaneously. Crystals of the bitter principle were deposited. This is probably pure *ilicin*. (*A. J. P.*, xxviii. 314.) Walter A. Smith (*A. J. P.*, 1887, 1668) obtained a resin soluble in alcohol by the ether extraction, and in the portion of this soluble in water he obtained evidences of a glucoside. This species is said to possess the same medical properties as *I. aquifolium*, L.

Ilex Paraguayensis, A. St.-Hil., the *I Maté* of St.-Hilaire, yields the celebrated *Paraguay tea*, so extensively consumed as a beverage in the interior of South America. It is a small tree or shrub growing wild along the streams in Paraguay, and also cultivated for the sake of its leaves, which are the part used. These are stripped from each plant every two or three years. The period of their collection extends from December to August, sometimes beginning earlier but never continuing later. Companies are formed who penetrate far into the forest at a distance from the settlements, and devote a long time to the collection and preparation of the leaves. These are first dried by exposure to heat, and are then reduced to powder more or less fine, which is kept for several months protected from moisture, and then packed in sacks and delivered to commerce. (A. Demersay, *Ann. de Thérap.*, 1868, 72; see also *Pharmaceut. Record*, May 1891.) They have a balsamic odor and bitter taste, and are usually at first disagreeable to the palate. They have a pleasant and corroborant effect upon the stomach; but, when very largely taken, are said to purge and vomit. They are used in the form of infusion, which is prepared from the entire leaves as we prepare tea; or, under the name of *cha maté*, a fine powder is put in a cup of hot water by the drinker, and after a moment's stirring, the fluid is sucked up by means of a tube expanded below,

and pierced with fine holes, so as to strain out the powder. They contain, besides other substances, a peculiar tannin and the alkaloid caffeine in variable amount. In the analysis of D. A. Strauch, the leaves yielded 0·450 of theine, 20·880 of caffeotannic acid, 2·830 of gum, 5·902 of resin, chlorophyll, and wax, 1·200 of starch, 9·361 of protein compounds, 22·148 of cellulose, 8·640 of apotheme, 3·896 of salts, 8·100 of water, with a trace of volatile oil, and some sand and extractive. (*A. J. P.*, 1868, 314.) Some fresh leaves of *Ilex paraguayensis* grown in the Cambridge Botanical Gardens were found by A. H. Allen, after drying at 100° C., to contain: insoluble matter, 57·94 per cent.; tannin, by lead acetate method, 15·62; tannin, by cupric acetate method, 15·66; caffeine, 1·13; total ash, 6·14; soluble ash, 3·56. (*Com. Org. Anal.*, 2d ed., iii., Part II., 527.) Some elaborate proximate analyses of maté are also published by Theodore Peckolt. (*Pharm. Journ.* (3), xiv. 121.) The consumption of maté, or yerba, in South America is enormous. Although largely produced in the Argentine Republic, fourteen thousand tons of the leaves were in 1880 imported into that country from Brazil and Paraguay, and six thousand tons into the republic of Uruguay. For an interesting account of the method of preparation, and an elaborate analysis, see *P. J. Tr.*, vol. xvi. 1017.

The *Ilex vomitoria*, Soland. in *Ait. Hort. Kew.* (*I. cassine* of Walt.), is a handsome evergreen shrub, growing in our Southern States, and especially abundant along the southern coast of Florida. Analysis of its leaves by Venable (*A. J. P.*, 1885, 390) gave 7·89 per cent. of tannic acid and 0·27 per cent. of caffeine. It is the *cassena* of the Indians, who formerly employed a decoction made from the toasted leaves, called *black drink*, both as a medicine and as a drink of etiquette at their councils. It acts as an emetic. The leaves of the *Ilex dahoon*, Walt. (now *I. cassine*, L.), have similar properties, and are also said to have entered into the composition of the black drink. The leaves of the *Ilex cassine*, Walt. (now *I. vomitoria*, Soland.) known as *Yaupon* by the Indians, yielded to Mr. H. M. Smith 0·011 per cent. of volatile oil and 0·122 per cent. of caffeine. (*A. J. P.*, xliv. 217.)

ILLICIUM FLORIDANUM. Ellis. *Florida Anise-tree.* This is an evergreen shrub or small tree, of the nat. ord. Magnoliaceæ, growing in Florida, along the coast which bounds the Gulf of Mexico. The bark, leaves, and probably also the seed-vessels are endowed with a spicy odor and taste, analogous to those of anise. H. C. C. Maisch (*A. J. P.*, 1885, 280) obtained from the leaves a crystalline alkaloid to which the bitter taste is due, tannin, and a resin. In the root-bark and capsules he found volatile oil and a crystalline principle, melting at 110° C., insoluble in alcohol and ether, but soluble in chloroform, and neutral to test-paper. It is a question worthy of investigation whether the capsules of this plant might not be substituted for those of the *Illicium anisatum* or *star aniseed.* (See *Illicium.*) Another species, *I. parviflorum*, a shrub found by Michaux in the hilly regions of Georgia and Carolina, has a flavor closely resembling that of sassafras root.

IMPATIENS. *Impatiens fulva*, Nutt. (now *I. biflora*, Walt.); and *I. pallida*, Nutt. (now *I. aurea*, Muhl.). *Touch-me-not. Jewel-weed. Balsam-weed.* These two species of Impatiens (nat. ord. Geraniaceæ), the former of which is better known commonly as *Spotted Touch-me-not* and the latter as *Pale Touch-me-not*, are indigenous, annual, succulent plants, from two to four feet high, growing in low, moist grounds, and flowering in July and August. They may be known by their tender, juicy, almost transparent stems; by their yellow flowers, which in the latter species are pale and sparingly punctate, in the former are deeper colored and crowded with dark spots; and by their capsules, which burst elastically, and curl up with the slightest pressure. They probably possess properties similar to those of the *I. noli-me-tangere*, Crantz. (now *I. noli-tangere*, D. Don), of Europe, which has an acrid burning taste, and, when taken internally, acts as an emetic, cathartic, and diuretic, though considered dangerous, and therefore little used. The late Dr. Ruan, of Philadelphia, employed with great advantage, in piles, an ointment made by boiling the American plants, in their recent state, in lard. The flowers may be used for dyeing yellow. The *I. balsamina*, L., or *balsam-weed, touch-me-not*, etc., of the gardens resembles the other species in its effects.

IMPERATORIA OSTRUTHIUM. L. *Masterwort. Rhizoma Imperatoriæ*, P. G. *Impératoire*, Fr. *Meisterwurz, Kaiserwurz*, G. An umbelliferous plant, indigenous in the south of Europe. The root has a strong odor, similar to that of angelica, and a pungent, biting, aromatic taste, attended by a flow of saliva, and followed by a glowing warmth which remains long in the mouth. E. M. Holmes (*P. J. Tr.*, March 17, 1877) noticed this root mixed with aconite in the London market, but this probably arose from carelessness, as masterwort is worth twice as much as aconite. A crystallizable, tasteless principle, called *imperatorin*, was extracted from the root by Wackenroder, and Gorup-Besanez found in the root another principle, to which he gave the name of *ostruthin.* Besides these two crystalline compounds, masterwort contains a volatile oil, composed of a hydrocarbon and an oxygenated compound, probably the aldehyde of angelic acid. (Wagner, *Journ. Pr. Chem.*, lxii. 283.) Jassoy (*Apoth. Zeit.*, v. 150) has since investigated the substance ostruthin and gives it the formula $C_{18}H_{20}O_3$. He states that it does not contain a methoxyl group but a phenol-like hydroxyl. By fusion with caustic potash, it yields along with a carbonaceous residue small amounts of resorcin and acetic and butyric acids. By the action of bromine in chloroform solution it is changed in the presence of acid sodium carbonate into *tribromostruthin*, $C_{18}H_{19}Br_3O_3$ (Schmidt, *Pharmaceutische Chem.*, Bd. ii., 3te Auf., 1510.) The root of masterwort was formerly considered alexipharmic, stomachic, corroborant, emmenagogue, diuretic, and diaphoretic, and was used in a wide circle of complaints with so much supposed success as to have gained for it the title of *divinum remedium.* It is, however, merely a stimulant aromatic, which in this country is unknown as a remedy.

INCASSA POISON. This is an African ordeal bark, which has been studied by Prof. Liebreich, who found in it a very violent cardiac poison.

INDELIBLE INK. This is prepared by dissolving two drachms of silver nitrate and a drachm of gum arabic in a fluidounce of distilled water, colored with a little Indian ink. It is used for writing with a pen on linen and muslin. The place to be marked is prepared by being moistened with

a solution of two ounces of crystallized sodium carbonate and two drachms of gum arabic in four fluidounces of water, and then dried. This alkaline solution, called *mordant*, decomposes the nitrate, and protects the cloth from the action of the free nitric acid. At the end of twenty-four hours the spot is to be washed.

Prof. Redwood, of London, proposes the following indelible ink, not requiring the use of a mordant. Dissolve an ounce of silver nitrate and an ounce and a half of crystallized sodium carbonate, separately, in distilled water, and mix the solutions. Wash the precipitated silver carbonate, and, having introduced it, still moist, into a Wedgwood mortar, rub it with eight scruples of tartaric acid, until effervescence ceases. Then add strong solution of ammonia, just sufficient to dissolve the silver tartrate formed (about two fluidounces). Lastly, having mixed in half a fluidounce of archil, half an ounce of white sugar, and an ounce and a half of powdered gum arabic, add sufficient distilled water to make the whole measure six fluidounces. M. Soubeiran has given the following formula for indelible ink, which he considers simpler than Mr. Redwood's. Dissolve 8 parts of crystallized silver nitrate, 3 of copper nitrate, and 4 of sodium carbonate, in 100 of ammonia water, and add to the solution a little gum. The marks produced by silver nitrate on linen or muslin may be completely removed by moistening them with a solution of corrosive sublimate or of potassium cyanide in distilled water, and afterwards washing them.

M. Jules Guiller has devised the three following formulas for marking-inks for linen. 1. Silver nitrate 11 parts; distilled water 85; powdered gum arabic 20; sodium carbonate 22; solution of ammonia 20. Dissolve the sodium carbonate in the water, rubbing the solution with the gum, and the silver nitrate in the ammonia. Mix the solutions, and gradually heat the mixture in a flask until it boils. This ink flows readily from a pen. 2. Silver nitrate 5 parts; distilled water 12; powdered gum arabic 5; sodium carbonate 7; solution of ammonia 10. The ingredients are treated as in the preceding formula, with the exception that the mixed solution is heated until it becomes of a very dark color, and is reduced about one-twentieth in volume by evaporation. This ink is suitable for marking on linen with stamps. 3. Silver nitrate 17 parts; distilled water 85; powdered gum arabic 20; sodium carbonate 22; solution of ammonia 42; copper sulphate 33. Dissolve the silver nitrate in the ammonia, the sodium carbonate in 25 parts of the water, and the gum in the remaining 60. Then mix with the soda solution, first the gum solution, and afterwards the silver solution. Lastly, add the copper sulphate. This ink has a blue instead of the dark brown color of the others. (See *A. J. P.*, 1853, 33.)

Dr. Boettger gives the following formula. 3·65 Gm. of aniline black are rubbed down in a porcelain mortar with 60 drops of concentrated hydrochloric acid, and 22 Gm. of alcohol. This solution is mixed with a hot solution of 1·82 Gm. of gum arabic in 85 Gm. of hot water. This ink does not attack steel pens, and is not acted upon either by strong mineral acids or by alkalies. If the aniline black solution be diluted with shellac solution (21 Gm. in 85 of alcohol) an aniline black lake will be obtained, which is suited for coloring wood and leather.

Herberger recommends the following indelible ink for other purposes than marking linen. Dissolve wheat gluten, carefully freed from starch, in a little weak acetic acid, and dilute the solution with rain-water, so as to have about the strength of wine vinegar. For every four ounces of the solution add ten grains of the best lamp-black, two grains of indigo, and a little oil of cloves. This ink has a beautiful black color, and cannot be removed by chlorine or dilute acids.

Elsner states that an *indelible red ink* can be prepared as follows. Equal parts by weight of copperas and cinnabar, both in fine powder and sifted, are rubbed up with linseed oil with a muller, and finally squeezed through a cloth. The thick paste can be employed for writing or stamping woollen or cotton goods.

INDIAN GRASS OILS. The Indian grass oils are at least five in number,—namely, oils of citronella, lemon-grass, Indian or Turkish geranium, ginger-grass, and vertivert or cus-cus. They are derived from various tropical grasses of the genus Andropogon, but there is some confusion as to the particular species from which the individual oils are obtained. These oils are used solely for perfumery. (See later, under *Oils of Citronella* and *Lemon-grass.*)

INDIAN RED. A purplish-red pigment, brought from the island of Ormus in the Persian Gulf. It is *red ochre*, and owes its color to *ferric oxide.*

INDIAN YELLOW. This is a pigment manufactured from a yellow substance from India, called *purree.* Purree occurs in commerce in balls, from three to four ounces in weight, which are dark brown externally and deep orange within. It has a peculiar smell, closely resembling that of castor. This circumstance gave rise to the belief that it was of animal origin; but Stenhouse found it to consist of magnesia, united with a peculiar acid, which he names purreic (*euxanthic acid* of Erdmann), and which forms nearly one-half of the crude substance. *Purreic acid* is in small crystals of a light yellow color, dissolving sparingly in cold water, quite readily in boiling water, and abundantly in hot alcohol. It has at first a sweetish and then a slightly bitter taste, and possesses, in appearance, considerable resemblance to berberine. When acted upon by boiling nitric acid, it is finally converted into a new acid, crystallizing in yellow needles, called by Erdmann *oxypicric acid.* Purreic or euxanthic acid is monobasic, and has the formula $C_{19}H_{16}O_{10} + 3H_2O$. Dr. Stenhouse concludes that purree is probably the juice of some plant, saturated with magnesia, and boiled down to a solid consistence. (*Philos. Mag.*, xxv. 321. See also *Chem. Gaz.*, 1855, 134.)

INDIGO. *Indicum. Pigmentum Indicum. Indigo*, Fr., G. This well-known and highly important dye-stuff is obtained from various species of Indigofera (nat. ord. Leguminosæ), especially *I. tinctoria*, L., and *I. anil*, L., and is said to be afforded also by other plants, such as *Wrightia tinctoria*, R. Br. (nat. ord. Apocynaceæ), *Polygonum tinctorium*, Ait. (nat ord. Polygonaceæ), *Galega tinctoria*, L. (now *Tephrosia tinctoria*, Pers.), and *Tephrosia apollinea*, D. C., both of the nat. ord. Leguminosæ, etc. For an interesting account of the manufacture in Manchuria of indigo from *Polygonum chinense*, see *American Druggist*, Aug. 1888. It does not exist ready formed, but is generated, during

fermentation, from another principle existing in the plant. This principle appears to have been isolated from *Isatis tinctoria*, L. (nat. ord. Cruciferæ), by Ed. Schunck, who has named it *indican*. Through the agency of the mineral acids, it is resolved into indigo and sugar; and perhaps the same result may take place in fermentation. Indican is yellow, amorphous, of a nauseous bitter taste, with an acid reaction, and readily soluble in water, alcohol, and ether. It contains nitrogen. (*P. J. Tr.*, xv. 166.) In the process of preparing indigo, the plant is macerated in water; fermentation takes place; the liquor becomes of a greenish color, and in due time is decanted; the coloring principle dissolved by the water absorbs oxygen from the air, and assumes a blue color, becoming at the same time insoluble; a gradual precipitation takes place, favored by the addition of lime water or an alkaline solution; and finally the precipitated matter, having been washed upon linen filters, is dried, shaped usually into cubical masses, and sent into market. The importations of indigo into the United States for the year 1898 were 3,097,340 lbs., valued at $1,815,411. Most of the indigo consumed in dyeing is brought from the East Indies, though considerable quantities are imported also from Guatemala and Northern South America. The present annual production of natural indigo is estimated to be as follows:

	Kilos.	Valued at
Bengal	4,000,000	$10,000,000
Madras	1,100,000	2,000,000
Manila, Java, Bombay	1,000,000	2,500,000
Central America	1,125,000	3,000,000
China and other countries	1,000,000	2,500,000
		$20,000,000

It was formerly produced in our Southern States, especially Florida, where the plant grows luxuriantly, and it still appears to be prepared there for local use. (See *A. J. P.*, xxvii. 473.) It is of an intensely blue color, but assumes a coppery or bronze hue when rubbed by a smooth hard body, as the nail. Heated to 287·7° C. (550° F.), it emits a reddish-violet vapor, which condenses in minute crystals. It is insoluble in water or alcohol, but is readily dissolved by concentrated or fuming sulphuric acid, because of the formation of *monosulphindigotic* and *disulphindigotic* acids, of which the first is difficultly soluble in water and the second easily soluble. The sodium salt of this latter constitutes the *indigo-carmine* of commerce. It is also soluble in nitrobenzol. For other solvents, see *American Chemist*, i. 472; *A. J. P.*, xliii. 562. According to Berzelius, indigo contains, among other ingredients, four distinct principles: 1, a substance resembling gluten; 2, a brown coloring substance; 3, a red coloring substance; and 4, a blue coloring substance, which is the principle upon which its value as a material for dyeing depends, and which seldom constitutes so much as one half of the indigo of commerce. This blue coloring matter is called *indigotin*. According to C. Méhu, if dissolved in a boiling mixture of carbolic acid with a little alcohol or 15 per cent. of camphor, on cooling it is deposited in crystals. (*A. J. P.*, xliv. 71.) By deoxidizing agents it is deprived of its blue color, which it recovers by exposure to the air, in consequence of the absorption of oxygen. Such is the case with the acid sulphites, and in a less degree with sulphurous acid. Certain volatile oils are said to have the same effect when boiled with tincture of indigo, as the oils of turpentine, peppermint, lavender, juniper, savine, or sage. (*Journ. de Pharm.*, 1859, 399.) Chlorine also destroys the blue color. M. Preisser has concluded, from an elaborate examination of the *coloring principles* of plants, 1, that these principles are colorless in the young plants; 2, that they acquire color by combination with oxygen; 3, that all the coloring matters, extracted from any one plant, are produced by the oxidation in different degrees of a single principle; 4, that they are deprived of color by substances having a strong affinity for oxygen, and reacquire it by contact with oxidizing bodies; and 5, that these coloring principles are acids, and the lakes which they form genuine salts. (*Journ. de Pharm.*, 3e sér., v. 263.) For modes of testing the value of any specimen of indigo, see *Sadtler's Industrial Organic Chemistry*, 448. The most important of the methods for the determination of the indigo blue may be summarized under three heads, —viz., oxidation methods, reduction methods, and sublimation of the pure indigo blue from the commercial product. A table of analyses of commercial samples with results according to the several methods above referred to will be found in Allen, *Com. Org. Anal.*, 2d ed., iii. 311.

The artificial production of indigo has been the subject of much investigation and effort in recent years. The problem was successfully solved by A. Baeyer, of Munich, who proposed several methods capable of commercial utilization.

A method which has been carried out on a large scale by the Baden Aniline and Soda Co., at Ludwigshafen, is to start with *cinnamic acid*, $C_9H_8O_2$, made artificially from benzaldehyde, which is changed into *ortho-nitro-cinnamic acid*, $C_9H_7NO_4$, and this by the intervention of the dibromine derivative into *ortho-nitro-phenylpropiolic acid*, $C_9H_5NO_4$, and this by the action of alkalies in the presence of reducing agents, like grape sugar or xanthogenates, is converted directly into *indigo blue*, $(C_8H_5NO)_2$.

A second method was by the action of dilute alkalies upon a solution of *o-nitro-benzaldehyde* in acetone according to the reaction $2C_6H_4(NO_2)CHO+2C_3H_6O=C_{16}H_{10}N_2O_2+2C_2H_4O_2+2H_2O$. A method of Heumann, also successfully carried out on a large scale, is to treat *phenylglycin*, $C_6H_5.NH.CH_2.COOH$, with alkalies, and then oxidize the resulting alkaline solution, when *indigotine* is formed.

Synthetically prepared indigotine, according to O. N. Witt (*Chem. Ind.*, xx. 454), can be produced at a price comparable with good quality indigo and cheaper than refined indigo. There are several points in its favor, such as purity of product, fineness of division, and its being readily tested.

Schunck first showed that all urines, whether pathological or not, contain an indigo-producing body in minute quantities. This body is commonly spoken of as *indican* in medical books. Its true chemical nature was first ascertained by Baumann, who showed that it was not a glucoside, like the indican of plants, but the potassium salt of a peculiar acid, *indoxylsulphonic acid*.

Indigo was at one time considerably used in medicine, but at present is very rarely if ever employed. It is said to produce, when taken in sufficient quantity, nausea, vomiting, purging with bluish dark stools, a dark violet or dark green

color of the urine, and sometimes to cause a menstrual flux. It has been especially used in *epilepsy*, *infantile convulsions*, *chorea*, *hysteria*, and *amenorrhœa*, from a scruple to an ounce, three times a day. For further details, see 16th ed. *U. S. D.*

INKS, COLORED. The following recipes are stated by the *Boston Journal of Chemistry* to be preferable to the solutions of aniline dyes, which are now so extensively used as colored inks.

Green. Two parts copper acetate, one part potassium carbonate, and eight parts water. Boil till half is evaporated, and filter.

Blue. Three parts Prussian blue, one part oxalic acid, and thirty parts water. When dissolved, add one part gum arabic.

Yellow. One part fine orpiment, well rubbed up, with four parts thick gum water.

Red. With the aid of a gentle heat dissolve four grains of carmine in one ounce of ammonia water, and add six grains of gum arabic.

Gold. Rub gold-leaf, such as is used by bookbinders, with honey till it forms a uniform mixture. When the honey has been washed out with water, the gold powder will settle at the bottom, and must be mixed with gum water in sufficient quantity.

Silver. Silver-leaf treated in precisely the same manner gives a silver ink. Both these inks may, when dry, be polished with ivory.

Black. Three ounces crushed nut-gall, two ounces crystallized ferrous sulphate, two ounces gum arabic, and twenty-four ounces water.

White. Fine French zinc white, rubbed up with gum water to a proper consistency.

INSECT POWDER. *Camomille de Perse*, Fr. *Persische Bertramblumen*, G. *Persian* or *Caucasian Insect Powder*, or *Guirila*, consists of the flowers of *Chrysanthemum roseum*, Web. et Mohr. (*C. carneum*, M. von Bieb; *Pyrethrum coronopifolium*, Willd.; *P. carneum*, Bieb; *P. roseum*, Lindl.); and *C. marschallii*, Aschers (*Pyrethrum roseum*, Bieb), growing upon the Caucasian mountains, Armenia and Northern Persia, at an elevation of about a mile. *Dalmatian Insect Powder* is the product of *Chrysanthemum cinerariæfolium*, Benth. et Hook., also Vis., also (Trev.) Bocc. (*Pyrethrum cinerariæfolium*, Trev.), and it is more powerful than the Caucasian powder. The plant is now being cultivated on a large scale in California, and as more care is given to the preservation during drying of the color and of the volatile oil than in Dalmatia, the California product is said to be superior to the foreign drug. (*Chem. and Drug.*, August, 1889; see also for method of cultivation *Reports of the Fourth U. S. Entomological Commission*, 1885.)

The insect powder of commerce varies in color from yellow, yellowish brown, or brownish yellow to yellowish green, the finer qualities verging towards brown and the poorer towards green. Brilliant yellow powder should be viewed with suspicion. On microscopical examination of an insect powder, it will be found to consist of fragments of involucral scales composed of sclerenchyma, perhaps bits of stems composed of collenchymatous cells, pollen grains, fragments of the corolla and of its epidermis and papillæ. The absence or scarcity of pollen in the powder shows the absence or scarcity of the flowers in the drug; whilst the proportion of collenchymatous tissue indicates the proportion of stems. As the activity of the insect powder resides in the flower, specimens containing little of the flowers or much of the stems should be rejected. The powder yielded by the Dalmatian plant can usually be distinguished from Persian insect powder by the following characters. The outer surface and edges of the scales of the Dalmatian flowers contain numerous hairs, consisting of a long cell with attenuated ends placed horizontally upon a one- to three-celled stalk. The Persian flowers are almost entirely glabrous, a white hoariness being found only at and near the base of the scales, and very few hairs near the apex; the hairs are of the same structure as the preceding, only the terminal cell being much longer. Sclerenchymatous cells are much more numerous in the Persian than in the Dalmatian. The so-called *Hungarian* or *Russian daisy*, probably a species of the subgenus *Leucanthemum*, has been quite largely used as an adulterant. The importance of the adulteration is increased by the fact that the Hungarian daisy appears to be entirely free from insecticidal properties. The Hungarian daisy is distinguished from the true Pyrethrum by the orange-yellow disk florets, by the depression of the involucre, by its prominent dark receptacle, and by the absence of pubescence and pappus. The odor is less pungent than that of the true insect flower, being more like that of matricaria. The difference in odor is more pronounced on infusing in warm water. The Hungarian daisy yields a powder somewhat darker in color than true insect powder. Microscopically, the Hungarian or Russian daisy differs only in the absence from the involucre and stems of the peculiar hairs seen on the scales of the true insect powder, and the presence in their place of certain hairs, consisting of from four to ten cells, and terminating with a much elongated, thin-walled, or inflated cell. There seems to be no recognizable difference between the pollen of the two plants which yield insect powder and of the Hungarian daisy. The presence of quassia, fustic, turmeric, and other adulterants may be made out by the aid of the microscope, and chrome yellow (salt of lead) chemically, but the powder of Hungarian daisy cannot be detected microscopically. According to George R. Durrant, however, the Hungarian powder yields 10 per cent. of ash, whereas true insect powder yields but 6·5 per cent.

Insect powder does not appear to be actively poisonous to man, though it is said to cause some confusion of head in those who sleep in close apartments where much of it is used. Upon the insects, however, which are apt to infest the person of man and animals, as well as bedding and sleeping apartments, it acts very destructively, first stupefying and then killing them. It is scattered over the person, upon the beds, about apartments, etc., and is even employed as a dressing for ulcers and wounds to prevent the formation of maggots. It also answers to preserve dried insects and plants in cabinet collections. The powder, exhausted by alcohol, is harmless to insects; its activity is therefore dependent upon some principle whose nature has not been positively determined. M. Trapp, and also Ivanel de Bellesme, assert that it is an alkaloid, whilst M. Rother denies that it is of such nature. (*A. J. P.*, xxv., 1857; Dragendorff, *Jahresbericht*, 1876, 121.) Mr. Texton has found it to be a soft resin. (*A. J. P.*, 1881, 491.) In a series of experiments, Prof. Riley has found that the fumes of the burning powder are very poisonous to insects, and for certain purposes afford a ready mode of application, but that generally an aqueous

infusion is the best and cheapest preparation. It is also used now in the form of cones made by making a mass with mucilage of gum, with the addition of a small quantity of potassium nitrate. After drying, these are ignited like a pastille. Twenty-five grains stirred up in two quarts of water were sufficient to kill young cotton worms. The infusion soon spoils. The tincture and the alcoholic extract are both efficient preparations. The tincture (one part to four) has been especially recommended, diluted with ten times its bulk of water, by F. Jager, to keep off vermin from the human body. According to Prof. Maisch (*A. J. P.*, 1869, 128), it is capable of causing a vesicular eruption like that produced by the poison ivy.

IODAL. This substance, prepared by the action of iodine upon a mixture of alcohol and nitric acid, is decomposed by an alkali into iodoform and formic acid. M. Rabuteau found it to resemble chloral in its actions on animals. (*Ann. de Thérap.*, 1870, 98.)

IODANTIFEBRIN. *Iodacetanilid.* $C_6H_4I.NH(C_2H_3O)$. This occurs in rhombic flakes melting at 181·5° C., very slightly soluble in cold water, easily soluble in alcohol and in glacial acetic acid. In the experiments of E. Munz (*Prag. Med. Wochensch.*, 1891), the physiological results following the administration of this remedy by the mouth were entirely negative, and neither iodine nor antifebrin could be recognized in the urine, the probable explanation of this being that the excessive insolubility of the drug prevents its absorption.

IODIC ACID. HIO_3. This is obtained by decomposing the calcium iodate with sulphuric acid (*A. J. P.*, xlvi. 558), or by heating iodine with nitric acid (sp. gr. 1·5), and allowing the crystals of iodic acid to separate on cooling. It has been proposed by M. Lutton as a remedy in chronic glandular enlargements and goitre, half a drachm of a 2 per cent. solution being injected into the affected part. (*Ann. de Thérap.*, 1874, 192.)

Its 5 per cent. solution has been highly commended as a hæmostatic, also as an astringent and alterative in *gonorrhœa* and other mucous membrane infections. Pencils made of it are also said to be a very useful caustic in *chancroids* and various other *ulcers*. In using it hypodermically it is essential to have an absolutely clean syringe. In *gastric hemorrhage* it may be given in the dose of from one to two grains (0.06–0·13 Gm.) three times a day in milk; in *gonorrhœa*, injections of 0·05 per cent. may be employed.

The *sodium iodate*, a white, odorless, crystalline substance, very soluble in water, has been recommended for internal use, but is much inferior to the iodides. Dose, from ten to fifteen grains (0·6–0·9 Gm.) in milk. As a local remedy it may be useful in tubercular and other inflammations of the nose and larynx, either pure or diluted. Subcutaneous injections of from one to three grains may be safely given to reduce adenopathies, relieve rheumatic swellings and pains, and in neuritis and nervous syphilis.

IODINE ALBUMINATES. *Eigon.* Dieterich (*Pharm. Centralb.*, xxxiii) has produced certain substances which he believes to be staple compounds of iodine and albumen, and useful internally and externally for iodization.

Alpha-eigon, a light brown, odorless, tasteless, and insoluble powder, contains 20 per cent. of combined iodine, which is set free by acids and more slowly by alkalies.

Alpha-eigon sodium, *sodium iodo-albuminate*, an almost colorless, odorless, and nearly tasteless soluble powder, contains 15 per cent. of iodine; proposed as a substitute for potassium iodide.

Beta-eigon iodized peptone, one-fifth of the iodine strength of potassium iodide, over which salt it is said to have the advantage for internal use of being readily absorbed without causing irritation. One hundred and fifty grains daily are said to be well borne by the stomach.

IODINE TRICHLORIDE. ICl_3. This compound occurs in reddish-yellow crystals; very soluble in water and alcohol; rapidly decomposed with liberation of iodine and chlorine when brought in contact with organic matter. It has been especially recommended by Belfield (*Brit. Med. Journ.*, Aug. 1892) as a powerful local antiseptic. A solution is prepared for medicinal use by suspending 5·5 Gm. of iodine in 22 Gm. of water, and passing in chlorine as long as it is absorbed by the well-cooled mixture. The solution contains 10 Gm. of iodine trichloride. The strength of the solution used is 1 to 5 per cent. Gauze sterilized by boiling and immersing in 1 to 10 per cent. and dried is said to retain iodine trichloride indefinitely.

IODIPIN. A yellow, oily fluid, of a purely oleaginous taste, said by Winternitz (*Deutsch. Med. Wochen.*, xxiii.) to be an iodine addition-product of sesame oil, and to contain 10 per cent. of iodine in chemical combination. It has been given successfully in *syphilis* and *scrofula*, in drachm doses (3·9 Gm.), three times a day, either pure or in emulsion.

IODOFORMOGEN. According to K. Gaab (*Pharm. Centralhalle*, 1898, xi. 189), iodoformogen is a chemical combination of iodoform and albumen. It occurs as a fine, loose, dry, non-conglutinating powder, having a faint acidulo-ethereal odor, and being two and one-half times as voluminous as powdered iodoform. According to Kromayer (*Berl. Klin. Wochen.*, xxxv. 1898), iodoformogen is more slow and continuous and certain in its local action than is iodoform, and has the other properties of iodoform which make it valuable in surgery, lacking the odor. It bears sterilization at 212° F., without change.

IODOL. *Tetraiodopyrrol. Pyrrol Tetriodide.* C_4I_4NH. This is a yellowish-brown shining powder, composed of long prismatic crystals soluble in alcohol, in three parts of absolute ether, chloroform, and fatty oils, but soluble in water only in the proportion of one to five thousand, tasteless, and without odor. It was discovered by Silber and Ciamician, and is made from the pyrrol obtained in Dippel's oil (bone oil), which, after purifying, is treated with a solution of iodine in potassium iodide, when the tetraiodide (iodol) precipitates. It is purified by redissolving in hot alcohol, and again precipitated by the addition of water. It contains nearly 89 per cent. of iodine. It is capable of being heated to 100° C. without decomposition,* but at 140·6° C. (285° F.) is decomposed with evolution of fumes of iodine. Sulphuric acid produces a green color with it.

When given in sufficient dose to animals, iodol causes emaciation, albuminous urine, fall of temperature, general loss of muscular power, and finally death from fatty degeneration of the liver and kid-

* Merck's bulletin states that the iodol when in alcoholic solution begins to decompose at the boiling point of alcohol, although dry iodol will bear 100° C., as above stated.

neys and other tissues. That iodol is capable of producing constitutional symptoms is shown by Dr. C. Lauenstein (*Therap. Gaz.*, 1887, 768), in a case in which the use of the drug as a surgical dressing caused dizziness, marked rise in the temperature, vomiting, and small irregular pulse of 136, albuminous urine, and apathy which did not subside for four days. Iodine was found in the urine for twelve days. Pallin also reports a case with similar symptoms. That iodol is a less dangerous topical application than iodoform is due to its slower absorption. Iodol may be employed for all purposes for which iodoform has been used. It has been found very valuable in the treatment of tubercular laryngitis, and may be blown into the larynx directly upon the ulcers without causing irritation. It has been used with asserted great success in the treatment of blennorrhagic and simple *vaginitis*, in *chancres* and other *ulcers*, in suppurative *adenitis*, and as an antiseptic dressing to wounds. Mazzoni's original solution was: iodine, one part; alcohol, sixteen parts; glycerin, thirty-four parts. One drachm of iodol forms with one ounce of ether a clear brown solution, which may be applied by the spray or brush to the nasal and other mucous membranes, on which it leaves a coating of iodol. Iodol pastilles are prepared by Wolfenden from one grain of iodol, one minim of glycerin, and eighteen grains of glyco-gelatin, and are by him strongly recommended for *laryngitis*. Iodol has also been used as an internal remedy. Assaky states that its effects in *tertiary syphilis* and in *scrofula* are extraordinary. Good effects have also been claimed for it in *diabetes*. The usual dose is two or three grains (0·13 or 0·19 Gm.) a day; but Assaky and Reck have given thirty grains (1·9 Gm.) a day with asserted good results.

IODOPHENACETIN. *Iodophenine.* $C_{20}H_{23}I_3N_2O_4$. To a solution of phenacetin in glacial acetic acid is added hydrochloric acid water, and then a solution of iodine in potassium iodide. The product forms crystals resembling those of potassium permanganate, melting at from 130°–131° C. with decomposition, and soluble in glacial acetic acid or alcohol. Decomposed by water. Dr. Scholvein (*Oesterr. Zeitsch. für Pharm.*, 1891) has found that this substance is a powerful germicide, and that it is locally very irritant, and when taken into the intestinal canal is decomposed with the liberation of iodine, and liable to produce iodine poison. The drug probably has no practical value.

IODOTERPIN. $C_{10}H_{16}I$. This compound of iodine and terpin is a dark brown liquid, having the odor of turpentine, soluble in ether, benzol, and chloroform, with a specific gravity of 119, and a boiling point of from 165° to 175° C. In a communication to the Twelfth International Medical Congress it was proposed by A. Lieven as a substitute for the tincture of iodine, and mixed with sterilizing kaolin, 1 to 20 per cent., as an antiseptic dusting powder.

IODOZONE. This is stated to be a solution of iodine in ozone. It has been brought forward as a remedial agent by M. Robin, an apothecary of Bourges. (*Journ. d'Hygiène*, Aug. 1892.)

IONIDIUM MARCUCCI. This name has been conferred by Dr. Bancroft upon a South American plant of the nat. ord. Violaceæ, supposed to be the source of a medicine used with great asserted advantage in Maracaibo and elsewhere, in *elephantiasis* and other cutaneous affections. A specimen, however, received from Dr. Bancroft, was found by Sir W. Hooker to be identical with the *Ionidium parviflorum* of Ventinat, which is now referred to *I. glutinosum*, Vent. The medicine is called by the Indians *cuichunchulli*, and grows at the foot of Chimborazo. It is said to be diaphoretic, diuretic, occasionally sialagogue, and in large doses emetic and cathartic. The root is the part used. For further information, see *A. J. P.*, iii. 125.

IRON-WOOD. *Ostrya virginica.* Willd. (Now *O. virginiana* (Mill.), Willd.) (Nat. ord. Cupuliferæ.) The wood of the Hop-Hornbeam is said to be tonic, antiperiodic, and alterative; and the fluid extract has been used in doses of from a half to one fluidrachm in *ague*.

ISATIS TINCTORIA. L. *Woad. Pastel.* (Nat. ord. Cruciferæ.) A biennial plant, indigenous and cultivated in Europe. The leaves have a fugitive pungent odor, and an acrid very durable taste; they have been used in scorbutic affections, jaundice, and other complaints, but are only valuable because of the indican present, which yields indigo blue. (See *Indigo*.) The leaves are prepared by grinding them to a paste, which is made into balls, placed in heaps, and allowed to ferment. When the fermentation is at an end, the mass falls into a coarse powder, which is woad.

ISOPYRUM THALICTROIDES. L. (Nat. ord. Ranunculaceæ.) F. A. Harsten believes he has found two alkaloids, *isopyrine* and *pseudoisopyrine*, in the root of this plant. (*A. J. P.*, xliv. 453.)

ISSUE PEAS. These are globular beads, of the size of a pea, made of woody substances of spongy structure, intended to be introduced into issues, abscesses, etc., for the purpose of promoting suppuration.

JACARANDA. Several species of this genus (nat. ord. Bignoniaceæ) are employed in *syphilis* in Brazil and other portions of South America under the names of *caroba*, *carobinha*, etc. Peckolt (*A. J. P.*, 1882, 134) has found in them a crystalline substance, *carobin*, besides resins and acids, such as *carobic* and *steocarobic acids*, and *carobon*, *carobore-linic acid*, and *caroba balsam*. Hesse (*Ann. Chem. und Pharm.*, 252, 150) found only an aromatic resin, but no alkaloid. The value of the remedy has been asserted in the *Brit. Med. Journ.*, vol. i., 1885. For further information, consult *P. J. Tr.*, 3d series, vols. v., xii., and xiv., and also *A. J. P.*, 1882.

JAMBOSA ROOT. This is the root of *Myrtis Jambos*, H. B. K. (now *Eugenia Jambos*, L.), of the nat. ord. Myrtaceæ, which is widely cultivated in the tropics under the name of the *rose-apple*. It has been found by A. W. Gerrard to contain an oleoresin, besides a crystalline principle, *jambosin*, $C_{10}H_{15}NO_3$. Lyons has also found in it minute quantities of an alkaloid. The decoction of the bark of the root is used as an astringent in *dysentery*, *gonorrhœa*, and *leucorrhœa*. (*P. J. Tr.*, March, 1884.)

JAMBU ASSU. *Piper Jaborandi.* The root of the *Piper jaborandi*, Vell. (nat. ord. Piperaceæ), is one of the jaborandis of Brazil, which is used by the natives as a sudorific, a diuretic, and a febrifuge. It is said to contain an alkaloid and a pungent oleoresin. (See *Pilocarpus*.)

JATROPHA MACRORHIZA. Benth. *Jicama.* This is a euphorbiaceous plant which inhabits Northern Mexico and the adjoining United States. It is a mild purgative, acting excessively in overdose, and is believed by the Mexicans to be chola-

gogue. The dose of the fluid extract is stated to be from one-half to two fluidrachms (1·9–7·4 C.c.).

JEFFERSONIA DIPHYLLA. (L.) Pers. *Twin-leaf.* (Nat. ord. Berberidaceæ.) This is a small, indigenous, herbaceous perennial. From a knotty rhizome arises a naked one-flowered scape about a foot in height, and leaves which stand in pairs on long footstalks. The flower is white, with a four-leaved colored calyx, and eight petals; and the fruit is a one-celled, obovate, substipitate capsule, dehiscent near the top, with many oblong seeds, united at the base. The plant grows in the Middle and Western States. The rhizome, which, with the rootlets attached, is the part used, has a brownish-yellow color, and a bitter, acrid taste, which resides in its cortical part, the inner portion being nearly tasteless. E. S. Wayne, of Cincinnati, found it to contain albumen, gum, tannic acid, starch, pectin, a fatty resin, hard resin, sugar, lignin, and a peculiar acrid principle, having acid properties and resembling polygalic acid, in which it is supposed that the virtues of the root reside. The root is said to be emetic in large doses, tonic and expectorant in smaller doses, and not unlike senega, as a substitute for which it is sometimes used. (*A. J. P.*, xxvii. 1.) According to Prof. Mayer, of New York, the rhizome of this plant contains a small quantity of berberine and a second white alkaloid. The pectin of Mr. Wayne he considers to be saponin. (*Ibid.*, 1863, 99.) Mr. A. W. Flexor has, however, proved the absence of berberine from the root. (*Amer. Drug.*, 1884.)

JELLIES. The form of jelly is sometimes a convenient method of administering medicines, especially the fixed oils, as cod-liver oil, castor oil, resinous juices, etc. The following is a formula recommended by Prof. Parrish and William C. Bakes. "Take of the fixed oil or liquid resin a *troyounce;* honey, syrup, each, *half a troyounce;* gum arabic, in powder, *two drachms;* Russian isinglass, *forty grains;* orange-flower water, *six fluidrachms.* Dissolve the isinglass, with the aid of heat, in half a fluidounce of the orange-flower water, replacing the water as it evaporates. Triturate the other ingredients, with the remainder of the orange-flower water, into a homogeneous mass in a warmed mortar, then add the hot solution of isinglass, stir the mixture as it cools, and set it aside to gelatinize." (*A. J. P.*, 1861, 4.) Any other aromatic water may be substituted for that of the orange-flower, and cinnamon water diluted with an equal measure of pure water would probably better cover the offensive taste. In reference to cod-liver oil, the bitter-almond or cherry-laurel water would be still more effectual, care, however, being taken, in this case, that the water be duly diluted, lest too large a dose of it be administered.

JUNIPERUS. *U. S.* 1880. *Juniper. Fructus Juniperi*, P. G. *Baccæ Juniperi. Juniper Berries. Genièvre, Baies de Genièvre*, Fr. *Gemeiner Wachholder, Wachholderbeeren*, G. *Ginepro*, It. *Enebro, Bayas de Enebro*, Sp.

Juniperus communis, L. (nat. ord. Coniferæ), is an erect evergreen shrub, usually small, but sometimes twelve or fifteen feet high, with numerous very close branches. The leaves are narrow, longer than the fruit, entire, sharply pointed, channelled, of a deep green color, somewhat glaucous on their upper surface, spreading, and attached to the stem or branches in threes, in a verticillate manner. The flowers are diœcious, and disposed in small, ovate, axillary, sessile, solitary aments. The fruit is formed of the fleshy coalescing scales of the ament, and contains three angular seeds.

The common juniper is a native of Europe, but has been naturalized in the United States. Northward it becomes a trailing shrub, seldom more than two or three feet high, spreading in all directions, throwing out roots from its branches, and forming beds which are often many rods in circumference. The name of *J. depressa* has been proposed for this variety. The common juniper flowers in May, but does not ripen its fruit till late in the following year. All parts of the plant contain a volatile oil, which imparts to them a peculiar flavor. The wood has a slight aromatic odor, and was formerly used for fumigation. A terebinthinate juice exudes from the tree and hardens on the bark. This has been erroneously considered as identical with *sandarach.*

The berries, as the fruit is commonly called, are sometimes collected in this country, and parcels are occasionally brought to the Philadelphia market from New Jersey. But, though equal to the European in appearance, they are inferior in strength, and are not much used. The best come from the south of Europe, particularly from Trieste and the Italian ports. They are globular, more or less shrivelled; about as large as a pea; marked with three furrows at the summit, and at the base with tubercles from the persistent calyx; and covered with a glaucous bloom, beneath which they are of a shining blackish-purple color. They contain a brownish-yellow pulp, and three ovate, long, bony, angular seeds. They have an agreeable somewhat aromatic odor, and a sweetish, warm, bitterish, slightly terebinthinate taste. These properties, as well as their medical virtues, they owe chiefly to a volatile oil. (See *Oleum Juniperi.*) The other ingredients, according to Trommsdorff, are resin, sugar, gum, wax, lignin, water, and various saline substances. The proportion of these ingredients varies according to the greater or less maturity of the berries. The volatile oil is most abundant in those which have attained their full growth and are still green, or in those which are on the point of ripening. In the latter Trommsdorff found 1 per cent. of the oil. In those perfectly ripe it has been partly changed into resin, and in those quite black, completely so. The berries impart their virtues to water and alcohol. They are very largely consumed in the preparation of gin.

The tops of juniper were formerly directed by the Edinburgh and Dublin Colleges. Their odor is balsamic, their taste resinous and bitterish, and they possess similar virtues with the berries.

Uses.—Juniper berries are gently stimulant and diuretic, imparting to the urine the smell of violets, and producing occasionally, when largely taken, disagreeable irritation in the urinary passages. They are chiefly used as an adjuvant to more powerful diuretics in dropsical complaints. The infusion is a good preparation. It is made by macerating an ounce of the bruised berries in a pint of boiling water, the whole of which may be taken in the course of twenty-four hours. The fluid extract is an eligible preparation, but for most purposes the oil is preferable. (See *Oleum Juniperi*, PART I.)

JUNIPERUS VIRGINIANA. L. *Red Cedar. Cèdre de Virginie*, Fr. *Virginische Ceder, Rothe Ceder*, G. The tops of this plant were formerly included in the Secondary List of the U. S. Pharmacopœia. The tree is an evergreen of slow growth,

seldom very large, though sometimes attaining a height of forty or fifty feet, with a stem more than a foot in diameter. It has numerous and close branches, which, in the young tree, spread out horizontally near the ground; but as the tree advances, the lower branches slowly decay, leaving the trunk irregular with knots and crevices. The leaves are very small, fleshy, ovate, concave, pointed, glandular on their outer surface, ternate or in pairs, and closely imbricated. Those of the young shoots are often much longer and spreading. The leaves closely invest the extreme twigs, increasing with their growth, till ultimately lost in the encroachments of the bark. The red cedar grows in all latitudes of the United States, from Burlington, in Vermont, to the Gulf of Mexico; but it is most abundant and vigorous in the southern section. The interior wood is of a reddish color, and highly valuable on account of its great durability. Small excrescences, which are sometimes found on the branches of the tree, are popularly used as an anthelmintic, under the name of *cedar apples*, in the dose of from ten to twenty grains (0·65–1·3 Gm.) three times a day. The tops have a pleasant odor, and a strong, bitterish, somewhat pungent taste. These properties reside chiefly in a volatile oil, and are readily imparted to alcohol. The leaves, analyzed by Mr. Wm. J. Jenks, were found to contain volatile oil, gum, tannic acid, albumen, bitter extractive, resin, chlorophyll, fixed oil, lime, and lignin. (*A. J. P.*, xiv. 235.) They bear a close resemblance to the leaves of *Juniperus sabina*, L., from which they can be certainly distinguished only by the difference of odor. The *oil of red cedar* is now an article of commerce: it is used principally in perfumery, and is one of the principal constituents of the popular extract of white rose. (*A. J. P.*, 1877, 186.) It possesses, in a marked degree, the well-known agreeable odor of the red cedar wood. *Cedren camphor*, $C_{15}H_{26}O = C_{15}H_{24} + H_2O$, may be obtained by cooling the oil until coagulated, and separating the crystalline portion by expression; the expressed liquid is *cedren*, $C_{15}H_{24}$, which, after rectification and distillation, has the sp. gr. 0·984 at 15° C. (59° F.), boiling at 237° C. (458·6° F.). Cedren may also be prepared from the cedren camphor by the dehydrating action of phosphoric anhydride, P_2O_5. The resemblance of red cedar to savine is said also to extend to its medical properties. It is, however, much less energetic, and has not acquired the confidence of the profession. Externally applied it acts as an irritant; and an ointment, prepared by boiling the fresh leaves for a short time in twice their weight of lard, with the addition of a little wax, is employed as a substitute for savine cerate in maintaining a purulent discharge from blistered surfaces. Sometimes the dried leaves in powder are mixed with six times their weight of resin cerate, and used for a similar purpose. But neither of these preparations is as effectual as the analogous preparation of savine.

The volatile oil, which resembles oil of savine in its medical properties, has been used for the purpose of producing abortion, and in some cases has caused death. The symptoms have been burning in the stomach, vomiting, convulsions, coma, and a slow pulse, with evidences of gastro-intestinal inflammation after death. (See Dr. S. C. Watt, *Boston Med. and Surg. Journ.*, vol. xl.)

Under the name of *cedar* are known in commerce various trees, some of which do not belong to the genus Juniperus. The wood of *Juniperus bermudiana* is said to be largely used in making pencils. The cedar of Lebanon, *Cedrus libani*, Barrel, and its two varieties, the African cedar, *C. atlantica*, Manetti, and the Indian cedar or deodar, *C. deodara*, Loud., do not appear to be distilled for oil. Other trees known as cedars are the West Indian white cedar, *Tecoma leucoxylon*, Mart.; the American red cedar, *Thuja occidentalis*, Linn.; the Californian white cedar, *Libocedrus decurrens*, Torr.; the New Zealand cedar, *Libocedrus bidwillii*, Hook.; the Australian red cedar, *Cedrela toona*, Roxb.; and the West India cedar, *Cedrela odorata*, Linn. The wood of the latter species is used in making cigar boxes, and, according to the Messrs. Schimmel, yields 3 per cent. of a volatile oil, has a specific gravity of 0·915, boils between 265° and 270° C., and has an optical rotation of 5·053° in a 100 Mm. tube. It is said to be a powerful insecticide. (*Pharm. Journ.*, August 29, 1896, 179.)

JURUBEBA. *Solanum paniculatum.* L. (Nat. ord. Solanaceæ.) Introduced by importers under the name of jurubeba, this plant was examined by Dr. Kobert, and found to contain no active principle, and to be inert. According to Dr. Peckolt, however (*Pharm. Rundschau*, 1889), true jurubeba is *Solanum insidiosum*, Mart., from which the results would have been more favorable. It is used in Brazil in *gonorrhœa* and *syphilis*.

KAIRINE. *Kairin* G. *Oxytetrahydromethylquinoline.* The hydrochloric acid compound of this base, $C_{10}H_{13}ON.HCl + H_2O$, is the commercial kairine (kairine M). Quinoline is treated with sulphuric acid, forming *quinoline-sulphonic acid*, which, fused with caustic soda, yields *oxyquinoline*, which is then reduced with tin and hydrochloric acid, forming *tetrahydroxyquinoline*, and this, on treatment with methyl bromide, yields *methyltetrahydroxyquinoline* or kairine. Kairine A is the corresponding ethyl compound, and has similar properties. Kairine, as brought into commerce, is readily soluble in water and alcohol, and forms a grayish-white, crystalline powder, with bitter, salty taste. Ferric chloride produces a dark brown color, which upon the addition of sulphuric acid turns purple.

Kairine belongs to the antipyretic remedies, and is without doubt capable, in doses of from five to ten grains (0·3–0·6 Gm.), of producing pronounced fall of temperature in fever, accompanied by copious sweating. It is, however, a cardiac depressant, which is said to act directly upon the cardiac muscles, and is very prone to produce cyanosis and collapse. The reports have been so unfavorable that, in the absence of advantage over antipyrin and antifebrin, kairine is no longer used in practical medicine.

KAIROLINE, M or A. *Tetrahydromethylquinoline*, or *Tetrahydroethylquinoline.* These bases differ from kairine in not containing oxygen. Their characters are similar. The sulphates are the commercial salts. For physiological action, see *Ber. Chem. Ges.*, xvi. 739.

KALMIA LATIFOLIA. L. *Laurel. Mountain Laurel. Broad-leafed Laurel. Calico-bush. Spoonwood. Kalmie*, Fr., G. This well-known ericaceous evergreen is found from New Brunswick to Florida and from Ohio to Louisiana, being especially abundant on the sides of hills and mountains. It is from three to ten feet in height. The leaves,

which are supposed to be possessed of poisonous, narcotic properties, have been found by Mr. Charles Bullock to contain gum, tannic acid, resin, chlorophyll, fatty matter, a substance resembling mannite, an acrid principle, wax, extractive, albumen, yellow coloring matter, lignin, and salts of potassium, calcium, and iron. (*A. J. P.*, xx. 264.) Mr. George W. Kennedy detected the alkaloid arbutin in them. (*Ibid.*, xlvii. 5.) Although chemists have failed to find the toxic principle in this plant, the leaves are popularly believed to be poisonous to sheep and other small animals, but are said to be eaten with impunity by deer, goats, and grouse. It is also affirmed that severe and fatal poisoning has been produced by eating grouse that have fed upon these leaves. (See 16th ed. *U. S. D.*) Scientific proof of the poisonous properties of the laurel still seems to be lacking. The leaves have been used internally in *diarrhœa* and in *syphilis*, and externally in various skin diseases. (See 16th ed. *U. S. D.*)

It is probable that other species of Kalmia, as *K. angustifolia*, L., or *sheep-laurel*, and *K. glauca*, Ait., or *swamp-laurel*, have properties identical with those of *K. latifolia*. A decoction of the leaves of *K. angustifolia* is used by the negroes of North Carolina as a wash for ulcerations between the toes.

KANDOL. *Canadol.* This is a light fraction of petroleum of great volatility, which is said to afford a very cheap and efficient means of rapidly freezing skin and subdermal tissues.

KAOLIN. *Porcelain Clay. Fuller's Earth.* This is a very pure hydrated aluminum silicate, of the average formula $Al_2(SiO_3)_3 + Al_2O(OH)_4$. It is a white, powdery clay, unctuous when moist. It has very notable power of clarifying and decolorizing oils both mineral and vegetable, and in recent years has been largely used for this purpose.

KAURI GUM. This is an amber-like substance, varying from a soft cream-white to an amber color, dug in large quantities from the soil of New Zealand. It is a resinous exudation from the *Dammara australis*, Lamb (now *Agathis australis*, Steuds.), of the nat. ord. Coniferæ, but as it first exudes and is found on the surface of the ground, it is not esteemed. For a full account of it, see *P. J. Tr.*, ix. 715. It yields on distillation an oil almost entirely composed of a terpene. (*A. J. P.*, 1881, 419.) *Baume Calédonien* consists of a solution of kauri gum in an equal weight of 90 per cent. alcohol. It has been used with alleged great success in the treatment of *wounds* and *ulcers*, of *eczema* and other skin affections, and as a substitute for collodion and the soluble sodium silicate. When applied to a well-cleansed and dried wound it leaves a slight deposit of resin as a varnish, which is not affected by friction or contact with water.

KEFIR. *Kephir.* This is milk which has undergone a peculiar fermentation caused by certain fungus-masses, which have been long known by the Tartars as *Kephir seed*, or as the *Millet of the Prophet.* They are white, irregularly roundish bodies, with a very rough furrowed surface, a tough gelatinous or, when dried, cartilaginous consistency, of about the size of a walnut. They have been found by morphologists (C. D. Spivak, *N. Y. Med. Journ.*, 1896) to be composed of three different organisms. 1. *Saccharomyces cerevisiæ* (Meyen), or the yeast fungus; 2. *Bacillus acidi lactici* (Pasteur); and 3. *Dispora caucasica*, Kern; or *Bacillus kephir* (Sorokin), a rod-shaped bacterium. For an analysis of kefir, see König's *Nahrungs- und Genussmittel*, 3te Aufl., Bd. i. 420.

For the methods used by the Tartars in preparing kephir, see the previous editions of the *U. S. D.*, also the paper by Spivak. The method of Dmitrieff, which may be practised by any one having the kephir grains, is described in the *New York Med. Journ.*, Jan. 1896. According to Spivak, the changes in milk during kephirization are as follows. 1. Fat, salts, and water remain unchanged. 2. The quantity of lactose is gradually lessened from 30–50 per mille to 16–30 per mille in the second-day kephir, and to 12–20 per mille in the third-day kephir. 3. Lactic acid is increased from 3·5–8·6 per mille in second-day kephir to 6·3–9·0 in third-day kephir. 4. Alcohol is produced from 5·3–8·0 per mille in second-day kephir to 6·0–10·0 in third-day kephir. 5. Carbon dioxide is generated in quantities approximately 10 per cent. 6. A part of the casein—namely, about 10 per cent.—is transformed into acid albumin and peptone, 10 per cent. into hemialbumose, and the rest loses its lime, and therefore becomes digestible.

Kephir may be employed for the same purposes as are koumys and matzoon. It yields its constituents readily to assimilation, and is somewhat laxative and distinctly diuretic. It may be employed in various forms of *dyspepsia*, whether organic or functional, in *anæmia* and *chlorosis*, in *rachitis*, *chronic rheumatism*, *phthisis*, and other conditions of impaired nutrition.

KERATIN. The outer skin surface, the material of horns, hoofs, tortoise-shell, the finger-nails, all show a similar chemical composition, the empirical formula of which is said to be $C_{230}{}^{\cdot}{}_5H_{381}N_{70}O_{77}S_6$. The percentage of sulphur varies, however, considerably. Keratin is prepared by Unna by steeping parings of horn in a digestive liquid composed of pepsin, 1, hydrochloric acid, 1, and water, 11, as long as the shavings yield anything to the solvent. The residue is then dissolved in ammonia by maceration lasting several weeks, after which the solution is evaporated.

Gissmann boils the quills of birds' feathers in glacial acetic acid for from twenty-four to thirty-six hours in a retort furnished with a return condenser. A thick yellow-brown liquid is thus obtained, which is filtered through glass wool, evaporated on a water-bath to the consistence of an extract, and afterwards dried. Dieterich employs Gissmann's process, but before the treatment with acetic acid he subjects the feathers to ten hours' digestion in water and then to eight days' maceration in a mixture of equal weights of ether and alcohol, to eliminate fatty matters and cholesterin.

Keratin obtained by one of the foregoing processes is dissolved with the aid of a gentle heat either in acetic acid or ammonia, and the solution is allowed to clear by standing. Fischer recommends the employment of seven parts of keratin with either one hundred parts of acetic acid or a mixture of equal parts of ammonia and dilute alcohol. Keratin is insoluble in water, alcohol, ether, and dilute acetic acid, or acidulated pepsin solution. Diluted sulphuric acid on boiling changes it into leucin, tyrosin, and other products. It is soluble in concentrated acetic acid, alkalies, and ammonia.

Keratin has been employed for the purpose of coating pills, so as to enable them to pass through

the acid juices of the stomach and be dissolved in the alkaline intestinal fluids. It is proposed to use these coatings for four classes of medicine: 1. Medicines that can by prolonged contact cause irritation to the mucous membrane of the stomach: arsenic, salicylic acid, creosote, chrysarobin, quinine compounds, copaiba, cubebs, ferruginous preparations and especially ferric chlorides, opium, mercurial preparations and especially mercuric iodide and chloride, phosphorus, and all the tænifuge preparations. 2. Medicines that can injure the digestion by giving insoluble precipitates with pepsin and peptones: tannin, alum, lead acetate, preparations of bismuth, silver nitrate, corrosive sublimate, etc. 3. Medicines that are rendered inactive or decomposed by the gastric juice: alkali, bile, soap, calcium sulphide, iron sulphide, pancreatin, etc. 4. Medicines which should arrive in the intestines as concentrated as possible: kousso, santonin, extract of male fern, alkali. For the preparation of a solution of keratin suitable for the coating of pills several formulæ have been proposed, in all of which either acetic acid or ammonia is used as a solvent. The acetic solution might be used for coating pills containing salts of mercury, gold, or iron, arsenic, creosote, salicylic acid, tannin, alum, etc. On the other hand, an ammoniacal solution might be had recourse to for pills containing pancreatin, trypsin, bile, alkalies, iron sulphide, etc. If the pill mass should contain water, the pills would shrink and fissures would be produced in the keratin coating. It is, therefore, recommended to use in the making of these pills a mixture of yellow wax, one part, and suet or cacao butter ten parts. It is also necessary to avoid the use of vegetable powders and to employ in their place kaolin or charcoal powder.

When the pills are finished they should be dipped in cacao butter, rolled in charcoal powder, and then keratinized. For this purpose the pills, placed in a porcelain capsule, are sprinkled with a suitable quantity of keratin solution and then shaken together until the evaporation of the solvent takes place. This moistening and drying require to be repeated several times (as many as ten) before the layer of keratin is sufficiently thick. The process employed for coating pills with gelatin, which consists in dipping into the solution the pill fixed on the point of a needle, is not suitable here, for it leaves a hole through the keratin coating that can never be completely closed.

In order to insure that the keratin used is insoluable in the stomach, Unna recommends that a preliminary experiment should be made with calcium sulphide pills coated with it. If in the course of some hours after such pills are taken eructations of hydrogen sulphide are observed, it would indicate that the pills have been dissolved in the stomach. When the keratin is of good quality nothing of the kind should occur. Finally, the pills when placed in water should not liquefy or crack. (Bourquelot.)

KOSSALA. An Abyssinian remedy against *tape-worm.* (*Proc. A. P. A.*, xxvi.)

KOUMYS. *Kumys.* This is a liquor originally prepared by the Tartars from the milk of mares, but recently imitated with cow's milk to a great extent. It is said to be prepared in Tartary by putting the mare's milk in tall vessels whilst warm, adding koumys, one part for every ten of milk, stirring thoroughly every few minutes, and in three or four hours taking out and boiling in champagne bottles. (*Journ. de Pharm.*, 1875, 59.) For an account of the method employed in Russia, see *A. J. P.*, 1875, 261. The milk of the mares of the Steppes is stated to resemble that of women, being much richer than cow's milk in sugar and poorer in casein. For analysis, see *Journ. de Pharm.*, 1875, 62. The true koumys does not keep long, and therefore must be drunk at the place of production. For particulars as to the varieties of it, etc., see *Journ. de Pharm.*, Janv. 1875; also Truckenmiller, *A. J. P.*, 1880, 292. Dr. L. Wolff (*A. J. P.*, 1880, 291) has furnished, probably, the best formula for koumys: "Grape Sugar, half an ounce. Dissolve it in four ounces of water. Dissolve twenty grains of Fleischmann's compressed yeast, or well-washed and pressed out brewer's yeast, in two ounces of milk. Mix the two solutions in a quart champagne bottle, which is to be filled with good cow's milk to within two inches of the top. Cork well, secure the cork with wire, and place in a cellar or ice-chest, where a temperature of 10° C. (50° F.) or less can be maintained, and agitate three times a day. In three or four days the koumys is ready for use, and should not be kept longer than four or five days; it should be drawn only with a champagne tap." A beer bottle with patent cork may be substituted for the champagne bottle.

According to M. Stalberg, the composition of true koumys is as given below; other analyses may be found in the *Journ. de Pharm.*, 1875, 62. *Koumys of June.* In 100 parts, alcohol 1·65, fat 2·05, sugar of milk 2·20, lactic acid 1·15, casein 1·12, salts 0·28, carbonic acid 0·75. *Koumys of September.* Carbonic acid 1·86, alcohol 3·23, fat 1·05, lactic acid 2·92, casein and salts 1·21. M. Stalberg gives the following as the result of an analysis of Swiss koumys, made from skimmed cow's milk to which sugar had been added. Alcohol 3·622, lactic acid 0·256, sugar 2·376, albumen 2·099, butter 2·008, mineral salts 0·574, carbonic acid 1·997. Prof. Warnikiewicz found in koumys from cow's milk 6·32 per cent. of solid material, casein 3·08, butter 0·22, milk sugar 1·77, salts 0·33, lactic acid 0·62, alcohol 1·23 parts per hundred. (See also König's *Nahrungs- und Genussmittel*, 416–419.)

These fermented milks vary in composition with the milk they are prepared from. In the following analyses, the first three columns are taken from *A. J. P.*, 1887; the matzoon analysis is by Prof. Uffelmann.

	Cow's milk.	Koumys.	Kefir.	Matzoon.
Albumen	4·8	11·2	3·8	31·2
Butter	3·8	20·5	2·0	16·0
Sugar of milk	4·1	22·0	2·0	16·2
Lactic acid	..	11·5	9	8·3
Alcohol	..	16·5	8	2·1
Water and salts . . .	87·3	918·3	905	926·2

The taste of koumys is sweet but acidulous and peculiar. In small quantities it is said to increase the appetite, in large quantities to take the place of solid food, each quart of it containing, according to Dr. Victor Jagielsky, four ounces of solid food. (*N. R.*, i. 1.) In warm weather it is said to act as a diaphoretic, in cold weather as a diuretic. It is used especially in chronic constitutional diseases attended by emaciation, such as pulmonary *phthisis*, in chronic *abdominal catarrhs*, and in *albuminuria*. Jagielsky asserts that it is a powerful diuretic. (*Br. Med. Journ.*, 1879, ii. 288.) Hourowicz states that in Russia "the cure" requires from twelve to fifteen pounds of milk daily (two mares), and that

the koumys is taken in doses of from a teacupful to a tumblerful every half-hour or hour early in the morning.

KRESAMIN. This is a colorless aqueous fluid, with a characteristic carbolic acid odor, becoming yellowish on exposure to the air, which is said to be composed of 10 parts each of *trikresol* and *ethylene-diamine* in 500 parts of water. It is alleged to be antiseptic, non-toxic as used, and of high value in the treatment of *lupus* and various other skin diseases. (*Therap. Monat.*, April, 1898.)

KRYOFINE. *Methoxacet-p-Phenetidin. Methylglycollic Phenetidin.* $C_6H_4\begin{cases}OC_2H_5\\NH.COCH_2OCH_3\end{cases}$.

Kryofine crystallizes from aqueous solutions in needles, with a melting point of from 98°–99° C. (208·4°–210·2° F.). These crystals are white, and in moderate doses tasteless. In doses exceeding fifteen grains (0·9 Gm.), one has, after a few moments, the sensation of chewing willow bark. It is soluble in boiling water 1 in 52, in cold water 1 in 600. It is soluble also in alcohol, ether, chloroform, and the oils in excess. The physiological action of kryofine has not been worked out, but it has been shown that the fatal dose for mice is three grains, and for a medium-sized dog two hundred and one grains, death occurring by general paralysis and extreme slowing of respiration and pulse. Seventy-five grains (4·8 Gm.) given to man have produced no more serious effect than cyanosis with some lessened frequency of respiration. It can be detected in the urine from fifteen to twenty minutes after taking, disappearing in from six to eight hours. In doses of from two and a half to twenty-five grains it has been used and very strongly commended by Ebstein, Eichhorst, Hass, Morrison, and other clinicians as an analgesic for pains of purely nervous origin and antipyretic in various fevers. It has been found not to reduce the temperature so markedly and rapidly as some of the other allied drugs, and is believed to be a safer remedy with much less marked diaphoretic action.

The range of action of kryofine appears to be that of antipyrin. The assertion that it is less dangerous than that drug seems hardly to be sustained by the facts; depression and cyanosis have been produced by it in various cases. According to Ebstein, it can usually be demonstrated in the urine within twenty minutes after its ingestion, and disappears in six or sometimes eight hours. The usual dose is seven and a half grains (0·46 Gm.), to be repeated three or four times daily. In robust subjects the dose may be increased to twenty grains (1·3 Gm.), and sixty grains (3·9 Gm.) are said to have been given in the twenty-four hours with no injurious manifestations. In the feeble great caution is necessary in its employment.

LABDANUM. *Ladanum.* A resinous substance, obtained from various species of Cistus (nat. ord. Cistaceæ), especially *C. creticus*, L., *C. ladaniferus*, L., *C. cyprius*, Lmk., and *C. laurifolius*, L., small evergreen shrubs, inhabiting the islands of the Grecian Archipelago, and the different countries bordering on the Mediterranean. Upon the leaves and branches of these shrubs a juice exudes, which is collected by means of an instrument resembling a rake, with leather thongs instead of teeth, which is drawn over the plant. The juice adheres to the pieces of leather, and is afterwards separated. It is said that labdanum was formerly collected by combing the beards of goats which had been browsing upon the leaves of the cistus; and Landerer states that it is still gathered in Cyprus from sheep and goats, whose fleeces become loaded with it while they are pasturing. (See *P. J. Tr.*, xi. 6; xv. 301; xvi. 386, 779.) It comes chiefly from the Grecian Islands. Two varieties exist in commerce. The *purest labdanum* is in masses of various sizes, sometimes weighing several pounds, enclosed in bladders, dark red almost black externally, grayish internally when first broken, of the consistence of a plaster, softening in the hand and becoming adhesive, of an agreeable balsamic odor like that of amber, and of a bitter, balsamic, somewhat acrid taste. It is very inflammable, burning with a clear flame. On exposure it becomes dry, porous, and brittle. Little of this variety is found in the markets. *Common labdanum* is in contorted or spiral pieces, light, porous, blackish gray, hard and brittle, not softening between the fingers, similar in odor and taste to the preceding variety, but less inflammable, and mixed with sand and other earthy matters, which are obvious to the sight. A specimen exhibited at the International Exhibition of 1862, at London, was in flattish pieces, an inch or more thick, with remains of leaves on one side, of a very dark greenish-brown color, and a granular somewhat shining fracture. Guibourt found in 100 parts of the labdanum in masses, 86 parts of resin with a little volatile oil, 7 of wax, 1 of watery extract, and 6 of earthy substances and hair. In the contorted variety, Pelletier found 20 per cent. of resin, 3·6 of gum with calcium malate, 0·6 of malic acid, 1·9 of wax, 1·9 of volatile oil including loss, and 72 of a ferruginous sand. Schimmel & Co. (*Semi-annual Report*, April, 1893) state that they obtained from labdanum resin 0·91 per cent. of a golden-colored essential oil having the penetrating odor of ambergris. Its sp. gr. is 1·011 at 15° C. Labdanum is a stimulant expectorant, formerly given in catarrh and dysentery. At present it is employed only in plasters.

LAC. *Lacca. Resina* (*Gummi*) *Lacca. Laque, Gomme lacque*, Fr. *Lack, Gummilack*, G. A resinous substance obtained from several trees growing in the East Indies, particularly from *Croton laccifer*us, L. (nat. ord. Euphorbiaceæ), a form reduced to *C. aromaticus*, L., two species of Ficus, *F. religiosa*, L., and *F. indica*, L., both of the nat. ord. Urticaceæ, and, according to Valentine Ball, *Schleichera trijuga*, Willd. (nat. ord. Sapindaceæ), *Butea frondosa* (Roxb. ?), of the nat. ord. Leguminosæ, and *Zizyphus jujuba*, Lam. (nat. ord. Rhamnaceæ). Prof. Stillman states that *Acacia greggii*, A. Gray (nat. ord. Leguminosæ), and *Larrea mexicana*, Moric (Zygophylleæ), plants growing in Arizona, Colorado, and the Western territories, furnish both *shellac* and *lac dye*. (*A. J. P.*, 1880, 409.) Lac is found in the form of a crust, surrounding the twigs or extreme branches, and is generally supposed to be an exudation from the bark, owing to the puncture of an insect belonging to the genus Coccus, and denominated *C. lacca*. By some it is thought to be an exudation from the bodies of the insects themselves, which collect in great numbers upon the twigs, and are embedded in the concreted juice, through which the young insects eat a passage and escape. Several varieties are known in commerce. The most common are *stick-lac*, *seed-lac*, and *shell-lac*.

Stick-lac is the resin as taken from the tree, still encrusting the small twigs around which it origi-

nally concreted. It is of a deep reddish-brown color, of a shining fracture, translucent at the edges, inodorous, and of an astringent, slightly bitterish taste. Its external surface is perforated with numerous minute pores, as if made by a needle; and when broken it exhibits many oblong cells, often containing the dead insect. When chewed it colors the saliva beautifully red, and when burnt, diffuses a strong, agreeable odor. It is in great measure soluble in alcohol.

Seed-lac consists of minute irregular fragments, broken from the twigs and partially exhausted by water. It is of a light or dark brown color, inclining to red or yellow, feebly shining, almost tasteless, and capable of imparting to water less color than the stick-lac, sometimes scarcely coloring it at all. It is occasionally mixed with small fragments of the twigs.

Shell-lac is prepared by melting the *stick-lac* or *seed-lac*, previously deprived of its soluble coloring matter, straining it, and pouring it upon a flat smooth surface to harden. Valentine Ball (*Jungle Life in India*, *N. R.*, June, 1880) states that the stick-lac is first placed between two powerful rollers, which, by a simple arrangement, admit of any degree of approximation. The lac is then crushed off and is separated from the woody portions by screening; it is next placed in large tubs half full of water and is washed by the coolies, male or female, who, standing in the tubs, and holding a bar above with their hands, stamp and pivot about on their heels and toes until, after a succession of changes, the resulting liquor comes off clear. The disposal of the liquor drawn off at the successive washings will be spoken off farther on. The lac, having been dried, is placed in long cylindrical bags of cotton cloth, of medium texture, and about ten feet long and two inches in diameter. These bags when filled have somewhat the appearance of enormous Bologna sausages. They are taken to an apartment where there are a number of open charcoal-furnaces. Before each of these there are one principal operator and two assistants. The former grasps one end of the long sausage in his left hand, and slowly revolves it in front of the fire, and at the same time one of the assistants, seated as far off as the sausage is long, twists it in the opposite direction. The roasting before the glowing charcoal soon melts the lac in the portion of the bag nearest the operator's hand, and the twisting of the cloth causes it to drop into a trough formed of the leaves of the American aloe (*Agave americana*). When a sufficient quantity in a molten condition is ready in the trough, the operator takes it up in a wooden spoon and places it in a wooden cylinder some eight or ten inches in diameter, the upper half of which is covered with sheet brass. The stand which supports this cylinder gives it a sloping direction away from the operator. The other assistant, generally a woman, now steps forward, holding a strip of the aloe between her hands, and with a rapid and dexterous draw of this the lac is spread out at once into a sheet of uniform thickness, which covers the upper portion of the cylinder. The operator now cuts off the upper edge with a pair of scissors, and the sheet is then lifted up by the assistant, who waves it about for a moment or two in the air till it becomes quite crisp. It is then held up to the light, and any impurities (technically called "grit") are simply punched out of the brittle sheet by the finger. The sheets are laid upon one another, and the tale at the end of the day is taken and the chief operator paid accordingly. The sheets are placed in packing-cases, and when subjected to pressure break into numbers of fragments. The dark red liquor resulting from the washing above described is strained in order to remove all foreign materials. It is then passed into large vats, where it is allowed to settle. The sediment is subjected to various washings, and at last allowed to settle finally, the supernatant liquid being drawn off. The sediment when of proper consistency is placed in presses, from which it is taken out in the form of hard, dark purple cakes, with the manufacturer's trademark impressed upon them. This constitutes what is known in commerce as "lac dye." By the addition of mordants this dark purple substance yields the most brilliant scarlet dyes, which are not inferior to those produced by cochineal. Shell-lac is in thin fragments of various sizes, from half a line to a line thick, often somewhat curved, of a lighter or darker brown color, inclining more or less to red or yellow, shining, more or less transparent, hard and brittle, inodorous and insipid, insoluble in water, but easily and almost entirely soluble in alcohol, especially with the aid of heat. According to Oberdörffer, cold ether takes from shell-lac only about 5 per cent., consisting of wax; and adulteration with resins soluble in ether is thus readily detected. (See *A. J. P.*, 1861, 313.) An alcoholic solution of shell-lac usually needs clarification (due to suspended wax); by agitating the solution with six parts of powdered chalk, decanting and filtering, it becomes transparent.

A variety of lac is mentioned by writers, in the form of cakes, called *cake-lac* or *lump-lac* (*lacca in placentis*); but this is at present rare in commerce.

According to John, lac consists of resin, coloring matter, a peculiar principle insoluble in alcohol, ether, or water, called *laccin*, a little wax, and various saline matters in small proportion. The resin, according to Unverdorben, consists of several distinct resinous principles differing in their solubility in alcohol and ether. The laccin is nearly or quite wanting in *shell-lac*, which also contains scarcely any of the coloring principle. Mr. Hatchett found in *stick-lac* 68 per cent. of resin, and 10 of coloring matter; in *seed-lac* 88·5 per cent. of resin, and 2·5 of coloring matter; in *shell-lac* 90·9 per cent. of resin, and 0·5 of coloring matter. The other constituents, according to this chemist, are wax and gluten, besides foreign matters. R. E. Schmidt (*Ber.*, 1887, 1285–1303) has prepared the lac dye in a pure crystallized state. He gives it the formula $C_{16}H_{12}O_6$, and calls it *laccaic acid*. It was obtained crystallized from ethereal solution. Caustic alkalies dissolve it, giving a magenta color. Baryta water forms a violet lake. Laccaic acid shows some analogy to carminic acid, but the colors they give on wool and silk are different. Laccaic acid is decomposed on heating with concentrated hydrochloric acid to 180° C., as well as on fusing with caustic potash.

The importations of shell-lac into the United States in 1896 were 6,056,957 pounds, valued at $1,210,802, and in 1897, 7,151,459 pounds, valued at $1,082,401.

Lac in its crude state is slightly astringent, and was formerly used in medicine; but at present it is

not employed. Shell-lac is wholly inert. Stick-lac and seed-lac are used on account of the coloring principle which they contain. Shell-lac, as well as the other varieties, deprived of their coloring matter, is applied to numerous purposes in the arts. It is the chief constituent of *sealing wax*. The best *red sealing wax* is made by melting together, with a very gentle heat, 48 parts of shell-lac, 19 of Venice turpentine, and 1 of balsam of Peru, and mixing with the melted mass 32 parts of finely powdered cinnabar. But common resin is often substituted in part for the lac, and a mixture of red lead and chalk for the cinnabar. The best *black sealing wax* consists of 60 parts of lac, 10 of turpentine, and 30 of levigated bone-black; the best *yellow sealing wax*, of 60 parts of lac, 12 of turpentine, and 24 of lead chromate. (Berzelius.) Lac is also used as a varnish, and forms an excellent cement for broken porcelain and earthenware. It may be dissolved in alcohol, oil of turpentine, benzin, or naphtha. For a method of preparing a colorless varnish from lac the reader is referred to *P. J. Tr.*, 1864, 338. Lac has been highly recommended as an adhesive material for the dressing of wounds, ulcers, etc. It is prepared for use by dissolving, with the aid of a gentle heat, in alcohol contained in a bottle, sufficient lac to give it a gelatinous consistence, and then closing the bottle. It is used by spreading it on the bandages.

LACTOPHENIN. *Lactyl-phenetidine.* $C_6H_4\begin{cases}OC_2H_5\\NH.CO.CH(OH).CH_3\end{cases}$. A white crystalline powder, without odor, having a feeble bitter taste, soluble in one part in five hundred of cold water, one in eight and a half parts of alcohol, and having a melting point of from 117·5° to 118° C. It is produced by the action of lactic acid on phenetidine in the presence of dehydrating substances.

We have very little definite knowledge in regard to the physiological action of lactophenin, but it probably resembles in general that of other remedies of the class. There is abundance of clinical reports to prove that lactophenin is an active antipyretic and analgesic, and that it may be substituted for the older drugs in the various febrile diseases in which they are employed. The statements of Landowski, that it is more calmative and hypnotic in its influence than is antipyrin or phenacetin, has been confirmed by Jaksch, by Jaquet, and by other observers. Jaquet puts it as between sulphonal and urethane as an hypnotic. When, in *pneumonia*, *typhoid fever*, or other infectious diseases, the nervous symptoms are very pronounced and the fever high, lactophenin would seem to be especially indicated. There is much clinical evidence to show that in *rheumatism* it is superior to the older remedies of its class, having indeed specific curative properties inferior to but resembling those of the salicylates.

The statements which have been made that its use is free from danger are, however, not correct. It sometimes produces an exanthematous eruption, which may be macular or diffuse. Dr. Wenzel (*Centralb. f. Inn. Med.*, xvii., 1896) reports a case in which, after the patient had been taking for two weeks fourteen grains of lactophenin a day, there was suddenly developed violent jaundice, with dark brown urine, without fever or slowing of the pulse, with colorless stools. Similar cases had been previously recorded by Strauss, and Franz Rield (*Zeitsch. f. Heilk.*, xvi., 1895) details two. Kronig (*Berl. Klin. Wochensch.*, 1895) has reported a case of poisoning, with methæmoglobin in the blood, cyanosis, and rapidly produced death.

That lactophenin resembles closely the remedies of its class in its physiological action is shown by the fact that it is eliminated, at least in part, by the urine as a paramidophenol.

Lactophenin may be given in doses of from five to twenty grains (0·3–1·3 Gm.), repeated in special cases up to a drachm and a half (5·8 Gm.) in a day.

LAGAM BALSAM. A thick, yellowish, fluorescent liquid, of a peculiar aromatic odor, and bitterish, acrid taste, resembling copaiba. (*A. J. P.*, 1883.)

LAKES. These paints are compounds of vegetable or animal coloring principles with alumina or other metallic oxide, and are usually obtained by adding alum or stannic chloride to the solution of the coloring matter in water, and precipitating by means of an alkali. The alumina or stannic oxide unites with the coloring matter at the moment of separation, and forms an insoluble compound. Lakes are obtained in this way from cochineal, madder, Brazil wood, seed-lac, French berries, etc.

LAMIUM ALBUM. L. (Nat. ord. Labiatæ.) Dr. Florain asserts that this plant is an active hæmostatic, and contains an alkaloid, *lamine*.

LANTANA BRASILIENSIS. Link. *Yerba Sagrada.* (Nat. ord. Verbenaceæ.) M. Negrete states that he has separated from this Brazilian verbena an alkaloid, *lantanine*, resembling quinine in its action upon the system, and actively antiperiodic in doses of from fifteen to thirty grains (0·972–1·94 Gm.) in the twenty-four hours, given directly after the paroxysm. (*T. G.*, 1885.)

LANTHANII NITRAS. *Lanthanium Nitrate*, $La_2(NO_3)_6.12H_2O$, occurs in large rose-colored prisms which are soluble in water and alcohol. This salt is employed as an antiseptic, preventing the growth of bacteria when used in solutions of the strength of 1 in 2000. (See *Central. f. Bacter. u. Parasit.*, 1897, xxi.)

LARICIS CORTEX. *Br.* 1885. *Larch Bark. Ecorce de Mélèze*, Fr. *Lärchenrinde*, G. The bark of *Pinus Larix*, Linn. (now *Larix europœa* D. C.), of the nat. ord. Coniferæ, was found by Aldridge to contain gum, starch, resin, and tannic acid of the kind which precipitates the salts of iron olive-green. Dr. John Stenhouse has obtained from it a peculiar volatile principle, which he has not found in other trees of the Pine family, and which, as it has feeble acid properties, he has called *larixinic acid* (*larixine*). It is obtained by evaporating an infusion of the bark to the consistence of syrup, and submitting the residue to distillation in a glass retort or silver alembic by means of a sand-bath cautiously heated. A portion of the larixinic acid comes over and condenses in crystals, but the greater part is dissolved in the liquid distillate. This on careful distillation deposits the impure acid, which may be purified by pressing it in bibulous paper, again crystallizing from a strong aqueous solution, and lastly subliming once or twice. Larixinic acid is most abundant in the young bark. It is in beautiful white, lustrous crystals, often more than an inch long, of a peculiar somewhat empyreumatic smell, and a slightly bitter and astringent taste, inflammable, volatilizing at 93° C. (199·4° F.) and melt-

ing at 153° C. (307·4° F.), soluble in 87·88 parts of water at 56° F., very soluble in boiling water, soluble in cold but much more so in hot alcohol, and sparingly soluble in ether. It readily crystallizes from its solutions. A very singular and characteristic property is that of forming, when added, in strong solution, in excess, to baryta water, a bulky, transparent, gelatinous precipitate, occupying the whole measure of the liquids if concentrated. The probable formula of the acid is $C_{10}H_{10}O_5$. The inner larch bark possesses astringent and gently stimulant properties, and is supposed to have a special tendency to the mucous membranes. It has been found particularly efficacious in *purpura* and other *hemorrhagic affections*, especially *hæmoptysis*, and has been given in *bronchitis* with copious expectoration, and in diseases of the urinary passages. It has been used also, mixed with soap and glycerin, as a local remedy in *psoriasis*, *chronic eczema*, and other cutaneous affections. Of the extract from three to five grains (0·20–0·33 Gm), of the tincture from thirty minims to a fluidrachm (1·9–3·7 C.c.) or more may be given every three or four hours.

LATHYRUS SATIVUS. L. (Nat. ord. Leguminosæ.) The *White* or *Chickling Vetch*, which is used in Europe as a food both by man and animals, produces, when taken too freely, a condition known as *lathyrismus*. Horses which have been fed on the plant for a considerable period drop while performing the lightest work, in consequence of paralysis of the hinder extremities, and in many cases death has followed from bilateral paralysis of the laryngeal recurrent nerves and consequent asphyxia. This laryngeal affection does not occur in the human subject, anddeath very rarely takes place. In man the muscles of the lower extremities below the knee are apt to be especially affected, the abductors more than the adductors. The muscles of the face, neck, and upper extremities are very rarely, if ever, attacked. The reflexes and the general sensibility are usually not influenced; but Giorgieri has seen the tendon reflexes increased. Cantani found that the galvanic contractility of the paralyzed muscle was altered, the descending galvanic current producing only very slight contractions, the ascending current no response, and on microscopic examination the transverse markings were found to be nearly obliterated by fat globules. Proust has attributed death in fatal cases to inflammation of the spinal cord; but in the great majority of instances recovery occurs, and when post-mortem examinations have been had, the spinal cord has been found normal. Astier obtained from the seeds a poisonous alkaline volatile liquid. According to him, this, being volatile, is not present in preparations such as pressed cakes made at a high temperature, which are consequently not poisonous. If, however, such cakes have been prepared at low temperature, they exhibit toxic properties, owing to the retention of the toxic principle. This is in conformity with the experience of the peasants in some parts of Europe, who mix the ground white vetch seeds with wheat flour, and boil the mixture for food.

LAUROTETANINE. This alkaloid has been found by M. Greshoff in a number of plants belonging to the *Laurineæ*. It is said to be a powerful poison, acting like strychnine on the spinal cord. It gives with Froehde's reagent a magnificent indigo-blue color, which on the addition of water changes to yellow; with Erdmann's reagent, a transitory bright blue color, becoming brown, and with more nitric acid it gives immediately a bright red-brown, and with pure nitric acid a dirty brown. It is soluble in excess of alkali. (*P. J. Tr.*, vol. xxi., 1891.)

LAURUS NOBILIS. L. *Sweet Bay. Laurier commun*, Fr. *Lorbeer*, G. *The Bay-tree. Laurus nobilis* is an evergreen tree of the nat. ord. Laurineæ, attaining in its native climate the height of twenty or thirty feet. Its leaves are alternate, on short petioles, oval-lanceolate, entire, sometimes wavy, veined, of a firm texture, smooth, shining, deep green upon their upper surface, paler beneath. The flowers are diœcious, of a yellowish-white color, and placed in small clusters of three or four together, upon a common peduncle in the axils of the leaves. The corolla is divided into four oval segments. The fruit is an oval berry, of the size of a small cherry, and when ripe of a dark purple, nearly black color. The bay-tree, so famous among the ancients, inhabits the countries bordering on the Mediterranean. Its leaves and fruit, and an oil expressed from the latter, are used.

The *leaves* have a fragrant odor, especially when bruised, and a bitter, aromatic, somewhat astringent taste. They yield by distillation a greenish-yellow volatile oil, upon which their properties chiefly depend. The volatile oil, of which the fruit yields 0·23 per cent., has a sp. gr. 0·88, and is solid at 0° C. It is largely composed of oxygenated compounds. The constituents thus far recognized are *myrcene*, *phellandrene*, *methyl-chavicol*, *citral*, *methyl-eugenol*, *chavicol*, and *eugenol*. (*Schimmel's Report*, April, 1897.) Water distilled from the leaves has their peculiar odor. The *berries* when dried are black and wrinkled, and contain two oval fatty seeds within a thin, friable envelope; or they may be considered as drupes, with a kernel divisible into two lobes. They have the same aromatic odor and taste as the leaves, but are more pungent. Besides an essential oil, they contain a fixed oil, which may be separated by expression or decoction. The *expressed oil*, which is obtained from the fresh fruit, is concrete, of a greenish color, and retains a portion of the volatile oil, which renders it agreeably aromatic. One of its chief constituents is the ether of *lauric acid*, the so-called *laurostearine*, $C_3H_5(C_{12}H_{23}O_2)_3$, which fuses at 45° C. The free acid may be obtained from this by saponification. It cannot be distilled without decomposition. Another constituent of the crude fat is *laurin*, $C_{22}H_{30}O_3$, which can be extracted by alcohol. It forms neutral, easily fusible prisms without odor or taste. Lard, impregnated with the odorous principle of the berries, and colored green by chlorophyll or sometimes by indigo and turmeric, is said to be often substituted for the genuine expressed oil. The sophistication may be detected by means of boiling alcohol, which dissolves the laurel oil. The leaves, berries, and oil of the bay-tree are excitant and narcotic, but at present are never used internally as medicines, and in this country are scarcely employed in any manner. Their chief use is to communicate a pleasant odor to external remedies. Dr. A. T. Thomson has found an infusion of the berries useful in *impetigo*.

LAVANDULA. *U. S.* 1880. *Lavandula vera.* D. C. *Lavender. Flores Lavandulæ*, P. G. *Lavender Flowers. Lavande, Fleurs de Lavande*, Fr. *Lavandelblumen, Lavandelblüthen*, G. *Lavendola*, It. *Espliego, Alhucema*, Sp.

Lavender is a small labiate shrub, usually not more than two or three feet high, but sometimes reaching six feet. The stem is woody below, and covered with a brown bark; above, is divided into numerous slender, straight, herbaceous, pubescent, quadrangular branches, furnished with opposite, sessile, narrow, nearly linear, entire, and green or glaucous leaves. The flowers are small, blue, and disposed in interrupted whorls around the young shoots, forming terminal cylindrical spikes. Each whorl is accompanied by two bracts. The corolla is hairy, glandular on the outside, tubular, and labiate, with the lower lip divided into three segments, the upper larger and bifid. The four stamens are within the tube. The calyx is tubular, blue-gray, hairy, five-toothed, the upper tooth largest and roundish rhomboid. The plant is a native of Southern Europe, and covers vast tracts of dry and barren land in Spain, Italy, and the south of France. In England it is very largely cultivated for commercial purposes, often covering many acres, and the English lavender is especially esteemed. For method of culture and detailed descriptions of the various varieties that have been educed, see *Bost. Med. and Surg. Journ.*, Aug. 1873, 165; also *P. J. Tr.*, x. 119; also Aug. 8, 1885, and Feb. 1890. It is cultivated in our gardens, and in this country flowers in August. All parts of it are aromatic. The spikes should be cut when they begin to bloom. Lavender flowers have a strong fragrant odor, and an aromatic, warm, bitterish taste. They retain their fragrance long after drying. Alcohol extracts their virtues; and a volatile oil upon which their odor depends rises with that liquid in distillation. Hager obtained from a pound of the fresh flowers from half a drachm to two drachms of the oil. Lavender is an aromatic stimulant and tonic, but is seldom given in its crude state. The products obtained by its distillation are much used in perfumery, and the volatile oil is official. (See *Oleum Lavandulæ*, PART I.)

LAWSONIA INERMIS. L. (Now *L. alba.* Lam.) *Henna Plant.* This is a shrub of the nat. ord. Lythrarieæ, growing in the Levant, Egypt, Persia, and India, and well known as the source of a dye-stuff denominated *henna*, much used throughout the Mohammedan countries of the East. It is largely cultivated in Egypt. The flowers have a strong, pungent odor; and a distilled water is prepared from them, used by the women as a cosmetic. The fruit is thought to have emmenagogue properties. But the leaves constitute the henna of commerce. They are used very extensively by the females to give an orange color to their feet and hands and a golden hue to their hair. They are also employed to stain common wood in imitation of mahogany. Henna is in the form of powder, which is strongly astringent. Abd-el-Aziz, of Cairo, Egypt, found in it a brown substance, of a resinoid fracture, having the chemical properties which characterize the tannins, and therefore named by him *henotannic acid.* (*Journ. de Pharm.*, 1863, 35.) Henna is used in medicine, both internally and locally, as a remedy in *jaundice* and *leprosy* and other affections of the skin.

LEAD SACCHARATE. PLUMBI SACCHARAS. *Saccharate of Lead.* Lead saccharate is made by saturating a solution of saccharic acid in water by freshly precipitated lead carbonate gradually added. As the acid becomes saturated, the lead saccharate falls in the form of a white powder, being insoluble in cold water, and but very sparingly soluble in that liquid boiling hot. From this Dr. E. Hoskins prepared his *lead nitro-saccharate*, by dissolving the saccharate in dilute nitric acid, containing only one part of the acid in twenty parts of the mixture, filtering the solution, and gradually evaporating. The nitro-saccharate is deposited in yellow crystals of the form of regular six-sided plates or prisms. By dissolving one grain of this salt, with five drops of pure saccharic acid, in a fluidounce of distilled water, a solution was obtained which, though slightly acid to test-paper, was perfectly bland. This solution has been used to dissolve urinary *calculi.* (See Pereira's *Mat. Med.*, 3d ed., 755.)

LEAD TANNATE. *Plumbi Tannas.* This is obtained by precipitating a solution of tannin with one of lead acetate, added drop by drop. It has been used as an external application with success by Dr. Fantonetti in two cases of *white swelling* of the knee-joint. He employed it at first mixed with a third of its weight of lard, and afterwards pure, the fresh precipitate admitting of application as an ointment. Autenrieth recommends it as a dressing to gangrenous *ulcers*, and it is probably peculiarly efficacious in *bed-sores.* With this intention, the precipitate, either uncombined or mixed in its dry state with simple ointment in the proportion of two drachms to the ounce, may be spread on linen and applied to the sore. Van den Corput uses it in *excoriations*, applying it freshly precipitated and rubbed up with glycerin. (*Ann. de Thérap.*, 1865, 266.) It is especially commended in *sore nipples.* (*Med. Record*, 1875, 575.) The preparation here described is a bitannate. Other lead tannates exist.

LECITHIN. $C_{42}H_{84}NO_3P$. In 1896 Danilewsky stated that this substance is capable of affecting very powerfully the development of young animals. In accordance with this assertion Charrin (*Sem. Méd.*, 1897) and Serono (*Therap. Wochensch.*, 1897) state that the effect is very extraordinary, accompanied by great increase in the assimilation of nitrogen and in the number of red blood-corpuscles. Whilst there is not at present sufficient reason for using lecithin in practical medicine, there is much for further investigation.

LEDUM PALUSTRE. L. *Marsh Tea. Rosmarinus Sylvestris. Marsh Cistus. Wild Rosemary. Lédon, Romarin sauvage*, Fr. *Porsch, Sumpfporsch, Wilder romarin*, G. A small evergreen ericaceous shrub, growing in swamps and other wet places in the northern parts of Europe, Asia, and America, and in the mountainous regions of more southern latitudes. The leaves have a balsamic odor, and an aromatic, camphorous, bitter taste; and contain, among other ingredients, volatile oil and tannin. For the properties of the volatile oil, see *Journ. de Pharm.*, 4e sér., xx. 244; also *Proc. A. P. A.*, xxv. 154. It contains *ledum camphor*, a stearopten, together with valerianic and other volatile acids, and *ericinol*, $C_{10}H_{16}O$. The tannin has been named *leditannic acid*, $C_{15}H_{20}O_8$. On boiling with dilute mineral acids it is decomposed, and *ledixanthin*, $C_{30}H_{34}O_{13}$, separates as a yellowish or reddish powder. (Thal, *Pharm. z. Russland*, 1883 268.) Thal also extracted *ericolin*, $C_{34}H_{56}O_{21}$. This is a glucoside, which on heating with dilute sulphuric acid decomposes into sugar and *ericinol*, $C_{10}H_{16}O$, a colorless, peculiar-smelling oil, which turns brown in the air, owing to oxidation. The leaves are thought to be narcotic and diaphoretic, and have

been employed in *dysentery* and in various cutaneous affections, particularly *leprosy* and *scabies*. In complaints of the skin they are used both internally and externally, in the form of decoction. In Germany they are sometimes substituted for hops in the preparation of beer. *Ledum latifolium*, Ait. (now *L. grœnlandicum*, Oeder), or *Labrador tea*, which is a larger plant than the preceding, is a native of North America, growing in damp places in Canada and the northern part of the United States. The leaves have an agreeable odor and taste, and are esteemed pectoral and tonic. They are said to have been used as a substitute for tea during the war for independence.

LEEK. *Porrum. Porreau*, Fr. *Lauch*, G. The bulb of *Allium Porrum*. L. (Nat. ord. Liliaceæ.) The leek is a biennial bulbous plant, growing wild in Switzerland, and cultivated in the gardens of Europe and this country for culinary purposes. All parts of it have an offensive pungent odor and an acrid taste, dependent on an essential oil, which is in a great measure dissipated by decoction, and may be obtained separate by distillation. The bulb, which is the medicinal portion, consists of concentric layers, like the onion, which it resembles in medical properties, though somewhat milder. It is generally stimulant, with a direction to the kidneys. Dose of expressed juice, a fluidrachm (3·69 C.c.).

LEONOTIS LEONURUS. R. Br. This handsome tropical labiate is said to possess purgative and emmenagogue properties. (See *P. J. Tr.*, May, 1885.)

LEONURUS CARDIACA. L. *Common Motherwort. Agripaume, Cardiaire*, Fr. *Hergespann, Wolfstrapp*, G. A perennial labiate herb, growing wild in this country in waste places, around dwellings, etc. It has a peculiar aromatic odor and a bitterish somewhat pungent taste, and its infusion or decoction is sometimes used in *amenorrhœa*, suppression of the lochia, and *hysterical affections*.

LEWISIA REDIVIVA. Pursh. *Spathum. Chita. Bitter Root.* The roots of this plant, of the nat. ord. Portulacaceæ, abundant in the Northwestern United States, are very widely used by the Indians as an article of food. For analysis and description, see *A. J. P.*, 1889.

LIATRIS SPICATA. Willd. (Now *Lacinaria spicata* (L.). Kuntze.) *Gay-feather. Devil's Bit. Colic Root. Button Snakeroot.* An indigenous perennial composite plant, growing in natural meadows and moist grounds throughout the Middle and Southern States. It has a tuberous root, and an erect annual stem, which terminates in a spike of beautiful, purple, compound flowers, appearing in August. The root is said by Schoepf to have a terebinthinate odor, and a warm, bitterish, terebinthinate taste; to be possessed of diuretic properties; and to be useful as a local application in *gonorrhœa* and *sore throat*. The leaves of the *Liatris odoratissima* are very largely employed in the Southern United States to flavor tobacco, and to preserve clothing, etc., from moths. As a preservative it is worthless. The agreeable odor is due to *coumarin*, $C_9H_6O_2$, which may be frequently noticed in crystals upon the surface of the smooth spatulate leaves. (*A. J. P.*, March, 1875; Sept. 1881; xlvii. 116; *N. R.*, 1882, 66.) Pursh informs us that *L. scariosa* and *L. squarrosa* are known in Virginia, Kentucky, and the Carolinas by the name of *rattlesnake's master*, and that their roots are employed to cure the bite of the rattlesnake. According to Wm. P. C. Barton, all the tuberous-rooted species of Liatris are active diuretics.

LIGROINE. *Ligroïn.* This name has been applied to a petroleum product which is chiefly used as a solvent. It boils between 80° C. and 120° C., and has a specific gravity varying between 0·710 and 0·730 (67°–62° B.).

LIGUSTICUM. *Radix Levistici*, P. G. *Livèche, Ache de Montagne*, Fr. *Liebstöckel*, G. Several species of this umbelliferous genus are employed as domestic remedies. The *Ligusticum levisticum*, L. (now *Levisticum officinale*, Koch), or *lovage*, of the south of Europe, is aromatic in all its parts, but only the root and seeds are used. The seeds are small, ovate-oblong, somewhat flattened, curved, strongly ribbed, and of a yellowish-brown color. The medical properties of lovage are closely analogous to those of angelica. It is a stimulant aromatic, and has been employed as a carminative, diaphoretic, and emmenagogue. The best form for administration is that of infusion. The coloring principle has been isolated by M. J. Nicklés, who gives it the name of *ligulin*, and suggests an important application of it that may be made in testing drinking-water. If a drop of its alcoholic or aqueous solution is allowed to fall into distilled water, it imparts to the liquid its own fine crimson-red color, which undergoes no change; but if limestone water be substituted, the red color disappears in a few seconds, and is followed by a beautiful blue. (*Journ. de Pharm.*, 1859, 329.) The root of the *Ligusticum sinense*, under the name of *kao-pén*, is largely used by the Chinese. In the Northwestern United States the large aromatic roots of *Ligusticum filicinum* (S. Wats.), *Osha, Colorado cough-root*, are employed to a considerable extent as stimulating expectorants. (See *A. J. P.*, 1890 and 1891.)

LIGUSTRUM VULGARE. L. *Troène*, Fr. *Rainweide, Hartriegel*, G. *Privet.* A shrub of the nat. ord. Oleaceæ, from four to ten feet in height, growing wild both in Europe and the United States, usually in hedges and by the roadside. The leaves, which have an astringent, bitter taste, and the flowers, which are small, snow-white, and of an agreeable odor, have been used in the form of decoction in sore throat and aphthous and scorbutic ulceration of the mouth. The berries are black, have a sweetish bitter taste, and are said to possess purgative properties, and to color the urine brown. They are sometimes used for dyeing. Death in a child between two and three years old is recorded by Mr. James Cheese in *P. J. Tr.* (2d ser., viii. 607), as due to the eating of privet berries. The bark was analyzed by M. G. Polex, who found a peculiar substance, which he denominated *ligustrin*, insoluble in ether and absolute alcohol, but soluble in water and diluted alcohol. Strong sulphuric acid gives with *ligustrin* a deep indigo-blue color. Kromayer (*Arch. Pharm.*, (2) cxiii. 19) proved that Polex's ligustrin was only impure *syringin*, $C_{19}H_{28}O_{10} + H_2O$. The large white crystals become anhydrous at 115° C., and fuse at 212° C. He found in addition (see Kromayer, *Arch. Pharm.*, (2) ci. 281) mannite, sugar, muco-saccharine matter, starch, chlorophyll, bitter extractive, bitter resin, tannin, albumen, and salts. (*A. J. P.*, xii. 347.) Kromayer found besides the *syringin* a crystallized bitter principle, fusing at a little over 100° C., which he named *ligustron*.

LILIUM CANDIDUM. L. (Nat. ord. Liliaceæ.) *Common White Lily.* This well-known plant

is a native of Syria and Asia Minor, but has been long cultivated in gardens. The bulb, which consists of imbricated fleshy scales, is without odor, but has a peculiar, disagreeable, somewhat bitter, and mucilaginous taste. It contains much mucilage, and a small proportion of an acrid principle, which is dissipated or destroyed by roasting or boiling. In the recent state it is said to have been employed with advantage in *dropsy*. Boiled with water or milk, it forms a good emollient cataplasm, more used in popular than in regular practice. The flowers have an agreeable odor, which they impart to oil or lard; and an ointment or liniment is sometimes prepared from them, and used as a soothing application in external inflammations. Vomiting, purging, drowsiness, etc., are said to have been produced in a little girl by the pollen of the *tiger lily*, *L. bulbiferum*. (Jeffries Wyman, *Am. Journ. of Med. Sci.*, 1863.)

LINDEN. M. Boussingault calls attention (*Journ. de Pharm.*, 4e sér., xv.) to a saccharine exudation which occurs upon the leaves of the European Linden, which he has found to have the same composition as manna of Mount Sinai.

LINT. *Linteum Carptum. Charpie*, Fr., G. the term lint is applicable to a substance prepared from linen. It is in fact linen made soft and somewhat fleecy by various mechanical processes, so as to render it suitable for the dressing of wounds. The qualities required in good lint are,—1, perfect softness, to prevent mechanical irritation to the wound; 2, looseness of texture, to render it capable of absorbing the secretions from the surfaces to which it is applied; 3, a certain tenacity, so that it may receive unctuous dressings, yet with a facility of being torn in one direction; and, 4, sufficient firmness of fibre to prevent small portions from being easily separated and remaining as foreign bodies in the wound. As formerly and still frequently made for domestic purposes, it consists of old linen scraped by means of a knife with the hand and thus brought into a soft flocculent state, almost destitute of visible fibres. It is obvious that, though this answers some of the above requisitions, it entirely fails to answer others, and is unfit for general surgical use. It will not readily admit of the application of cerates, and must very often leave portions of its substance in the wound, to serve as future sources of irritation. Much better is the old-fashioned lint, made by machines worked by the hand. This was formerly made in large quantities. Old linen was used for the purpose, such as shirts, sheets, table-cloths, etc., and generally in irregular pieces. This was first cleansed thoroughly by washing with soap and water, or by boiling with a weak lye of soda or pearlash. Sometimes, when colored, it was bleached before being washed. Thus prepared, it was operated on by a simple machine, in which the rag, wrapped round a cylinder, was submitted to the interrupted action of a knife made to descend upon it at intervals of one-eighth of an inch, so as to cut the thread in one direction. On being removed from the machine, the cut ends of the thread became untwisted and loose, giving a flossy character to the fabric. To render it smooth, it was passed through rollers, and its ragged edges were trimmed. Of course it had different degrees of fineness according to the character of the rags used; and this diversity rendered it fit for different purposes, the finer pieces being used merely as a dressing with unctuous matter to exclude the air, while the thicker were better adapted to the absorption of the liquid secretions.

In the progress of improvement, machines were invented and patented for manufacturing lint on the large scale. Thus made, it is distinguished in commerce as *patent lint*. This is generally prepared out of cloth manufactured for the purpose, and therefore has whatever advantage may be derived from uniformity of shape and consistence. In other respects it is doubtful whether it has any superiority over the old-fashioned article; especially as, in consequence of competition, cotton, being the cheaper article, has frequently been in part or altogether substituted for linen. It is said that lint may be rapidly prepared by attaching a piece of linen to the toothed cylinder of the common carding machine.

Cotton is in several respects inferior to linen for the preparation of lint; and, unless its presence in any manufactured article sold by this name be made known, it should be looked on as a fraudulent substitution. Its fibre is less soft and therefore more likely to irritate; it has much less absorbing power; and it conveys heat less rapidly. The following are methods by which it may be distinguished (Elsner). 1. A linen thread when held erect, and set on fire, appears, after the flame is extinguished, in a smooth continuous form, while cotton thread similarly treated has a tufted aspect. 2. Under a microscope which magnifies 300 diameters, the linen fibre appears to be a straight nearly solid cylinder, with a slender central canal; the cotton, flattened as a piece of tape, with a wide canal, and often twisted like a corkscrew. 3. The potassa test, proposed by Böttger, consists in exposing the doubtful substance to the action of a boiling concentrated solution of potassa. If made of linen, it will in two minutes assume a deep yellow color; if of cotton, it will either remain colorless, or will become very faintly yellow; and if the texture be composed of both, it will exhibit a streaked or mottled aspect. The examination must be quickly made, as the yellow color of the potassa becomes faint with time. 4. Sulphuric acid dissolves the linen fibre, while it leaves that of cotton little changed. 5. Linen thoroughly oiled has the transparent appearance of oiled paper; cotton remains white and opaque. 6. Tinctures of all organic red dye-stuffs, as cochineal, madder, etc., give a much deeper color to linen than to cotton, and cause a mottled appearance when the two are mixed.

Tow, and hemp in the state of *oakum*, have been employed for dressing wounds; but they are only applicable as exterior dressings to absorb the pus, when the discharge of this is very copious. Dr. L. A. Sayre prefers picked oakum to lint as more absorbent. (*Bost. Med. and Surg. Journ.*, lxvii. 84.) *Charpie*, so much used by French surgeons, generally consists of bundles of straight threads, each four or five inches long, made by unravelling old rather coarse linen.

LINUM CATHARTICUM. L. *Purging Flax.* Purging flax is a European annual plant of the nat. ord. Lineæ, six or eight inches high, having erect, slender stems, dichotomous near the summit, furnished with opposite, obovate-lanceolate, entire leaves, and bearing minute white flowers, the petals of which are obovate and acute. The whole plant is very bitter and somewhat acrid, and imparts its virtues to water, which acquires a yellow color. It

appears to owe its activity to a peculiar drastic principle, which has received the name of *linin*, and which is afforded most largely by the plant after the flower has fallen. Schroeder (*Neues Repert. Pharm.*, xi. 11) obtained it in lustrous, white, silky crystals, which are neutral in reaction and have a strong persistent bitter taste in alcoholic solution. Purging flax has enjoyed some reputation in Europe as a gentle cathartic, useful in muscular rheumatism, catarrhal affections, and dropsy with disease of the liver. Dose of the extract, from four to eight grains (0·26–0·53 Gm.); of the powder, one drachm (3·8 Gm.).

LIPANIN. This mixture of one hundred parts of olive oil and six parts of oleic acid, devised by Dr. Von Mering, has been considerably used, with asserted excellent results, as a substitute for cod-liver oil. Dose, from one teaspoonful to half a fluidounce (3·69–14·7 C.c.).

LIPPIA MEXICANA. (Probably *Cedronella mexicana*, Benth., of the nat. ord. Labiatæ.) A Mexican evergreen shrub, the leaves and stalks of which have been used in medicine as a demulcent and expectorant. Podwissotzki analyzed the herb, and found it to contain tannin, a quercetin-like principle, liquid volatile oil, and a camphor-like body which he named *lippiol*. (*Proc. A. P. A.*, 1886, 400.) Dose of concentrated tincture (1 to 4), from a half to one fluidrachm (1·8–3·69 C.c.).

LIQUIDAMBAR STYRACIFLUA. L. *Sweet Gum.* An indigenous tree (nat. ord. Hamamelidaceæ), growing in different parts of the United States from Connecticut to Florida, and flourishing also in Mexico, where, as well as in our Southern States, it sometimes attains a great magnitude. In warm latitudes a balsamic juice flows from its trunk when wounded. This has attracted some attention in Europe, where it is known by the name of *liquidambar* or *copalm balsam*, and is sometimes, though erroneously, called *liquid storax*. It is not afforded by the trees which grow in the Middle Atlantic States, but is obtained in the Western States bordering on the Ohio, and in those farther south, as far as Mexico. It is a liquid of the consistence of thin honey, more or less transparent, of a yellowish color, of a peculiar, agreeable, balsamic odor, and a bitter, warm, and acrid taste. By cold it becomes thicker and less transparent. It concretes also by time, assuming a darker color. It is sometimes collected in the form of tears, produced by the spontaneous concretion of the exuded juice. According to M. Bonastre, it contains a colorless volatile oil, a semi-concrete substance which rises in distillation and is separated from the water by ether, a minute proportion of benzoic acid, a yellow coloring substance, an oleoresin, and a peculiar principle, insoluble in water and cold alcohol, for which M. Bonastre proposes the name of *styracin*. The styracin of M. Bonastre has since been found to be *cinnamyl cinnamate*, $C_9H_9,C_9H_7O_2$, which is found together with the *ethyl*, *benzyl*, and other esters of cinnamic acid. Examined by Mr. W. P. Creecy, of Mississippi, it was found to contain, besides a volatile odorous principle melting at 65° C. and smelling of vanillin, and 30 per cent. of a hard resin (according to W. von Miller, *storesin*, $C_{36}H_{55}(OH)_3$), cinnamic acid as the prominent acid ingredient. If the storesin be repeatedly extracted with dilute potassium hydrate solution, it is separated into *α-storesin*, which is amorphous and melts at from 160°–168° C., and *β-storesin*, which forms white flocks melting at from 140°–145° C. Of these, the *β*-resin is first extracted, while the residue is nearly pure *α*-resin. The volatile oil mentioned above contains a hydrocarbon, *styrol* or *cinnamene*, C_8H_8, which changes on heating into the polymeric *metastyrol*, a colorless transparent solid, identical in composition. The results of W. L. Harrison, confirmed by Prof. Maisch (*A. J. P.*, xlvi. 160, 165), seem to prove that the American drug is identical with styrax, except in containing no water mechanically mixed with it.

Another product is said to be obtained from the same tree by boiling the young branches in water, and skimming off the fluid which rises to the surface. It is of a thicker consistence and darker color than the preceding, is nearly opaque, and abounds in impurities. This also has been confounded with liquid storax, which it resembles in properties, though derived from a different source. It is said to be used in Texas in coughs. (Gammage, *N. O. Med. and Surg. Journ.*, xii. 636.) For an account of the collection of American storax, see *Pharm. Rundschau*, 1895, 57.

Liquidambar may be employed for the same purpose as storax, and is used in the Southern United States, but it is almost unknown in the Northern States. The concrete juice is said to be chewed in the Western States in order to sweeten the breath. The bark of the tree is used with asserted great advantage in the Southern and Western States in *diarrhœa* and *dysentery*, especially in children. It is taken in the form of syrup, which may be prepared from the bark in the same manner as the syrup of wild cherry bark, according to the U. S. Pharmacopœia. The dose is a fluidounce for an adult, repeated after each stool. (*Am. Journ. of Med. Sci.*, N. S., xxxii. 126.)

Liquidambar altingia is said to exude a balsam in the Tenasserim provinces of India, somewhat resembling liquid storax. (See *P. J. Tr.*, viii. 243.)

LIQUOR FERRI DIALYSATUS. *Solution of Dialyzed Iron* was formerly recognized by the Br. Ph., but was dismissed at the last revision. It is made by treating a solution of ferric chloride with ammonia, whereby ferric hydrate is precipitated, which by agitation is dissolved, placing the thick liquid in a dialyzer, and suspending this in water, which is to be constantly renewed so long as any traces of hydrochloric acid are found in it. The following process has been used in the United States. To one hundred parts of solution of ferric chloride, sp. gr. 1·26, thirty-five parts of ammonia water, sp. gr. 0·923, may be gradually added. The precipitate which almost immediately forms is redissolved, and the solution introduced in the dialyzer, which is then suspended upon the water, contained in a suitable vessel. When this ceases to produce a precipitate with silver nitrate, or to show an acid reaction, it is assayed by evaporating 10 C.c. to dryness on a water-bath, to ascertain the amount of ferric oxychloride in solution; then the final solution is diluted so that it shall contain 10 per cent. of dry oxychloride.

Dialyzed iron is a solution of ferric oxychloride in water. Although the amount of chlorine present is very small, it is not correct to speak of it as a solution of ferric oxide. Its composition may vary from $Fe_2Cl_6,12Fe_2O_3$ to $Fe_2Cl_6,95Fe_2O_3$ (Graham), and solutions which contain a large quantity of oxide in proportion to chloride are less stable and more prone to gelatinize. Solutions

containing a large proportion of chloride may be evaporated to dryness, if care be used, without the residue becoming insoluble. The solution is of a transparent reddish-brown color, free from the usual astringent, styptic taste of iron preparations. It mixes in all proportions with distilled water, alcohol, syrup, and glycerin, but water containing any saline impurity is apt to cause precipitation. When gelatinization occurs, agitation with a small quantity of solution of ferric chloride will usually restore it to fluidity, care being observed not to add an excess. Contact with the alkalies should be avoided, even in minute quantity; indeed, it is best administered without addition of any kind, or simply diluted with distilled water.

The British Pharmacopœia formerly directed that its specific gravity should be 1·047, and "100 grains should afford a precipitate with a solution of ammonia which, washed, dried and ignited, weighs five grains." E. B. Shuttleworth (*Can. Pharm. Journ*, Dec. 1877) recommends a solution which has the sp. gr. 1·040 and yielding 5 per cent. of residue, when well dried on a water-bath, as the best for medicinal use. The specific gravity test can be relied upon, if the solution does not give a precipitate with silver nitrate or become of a blackish-blue color upon treatment with tannin, showing the absence of ferric chloride. (See also *N. R.*, 1879, 46, for a new process by F. Schneider, from *Schweiz. Wochenschr.*, 1878, 409.) There is good reason for believing that much of the so-called dialyzed iron found in commerce is made by adding freshly precipitated ferric hydrate to solution of ferric chloride until it ceases to be dissolved, and then filtering the solution. (Prof. Scheffer, *A. J. P.*, March, 1878.) *Ferrum catalyticum*, or *catalytic iron*, used on the Continent, is probably made in this way.

Solution of dialyzed iron has been very highly praised as a ferruginous tonic free from astringency, which can be given in enormous doses without producing headache or gastro-intestinal irritation. It is evident, however, that a preparation which will not pass through animal membrane cannot be absorbed: in fact, dialyzed iron is precipitated in the stomach and intestines as a ferric oxide, which is very slowly absorbed. Dialyzed iron is, therefore, not an eligible preparation. It is capable of acting as an antidote to arsenic by virtue of the readiness with which it yields hydrated ferric oxide. Dose, from twenty minims to a teaspoonful (1·3–3·7 C.c.).

LIQUOR MAGNESII BISULPHITIS. Mr. George Archibald, having found that magnesium bisulphite is capable of arresting the butyric acid fermentation, proposes a solution of it as a remedy in *heartburn*. He prepares it by treating the magnesium carbonate with sulphurous acid, adding to an ounce of water sixteen grains of the sulphite thus formed, and passing sulphurous acid gas through the mixture till a clear solution is obtained. (*P. J. Tr.*, 3d series, ii. 502.)

LIRIODENDRON TULIPIFERA. L. *Tulip Tree Bark. American Tulip Poplar Tree. White Tulip Bark. Ecorce de Tulipier*, Fr. *Tulpenbaumrinde*, G. This indigenous representative of the Magnoliaceæ attains in some situations a height of more than one hundred feet. The bark is of a brown or grayish-brown color, except in the young branches, on which it is bluish or of a reddish tinge. The leaves, which stand on long footstalks, are alternate, somewhat fleshy, smooth, of a beautiful shining green color, and divided into three lobes, of which the upper one is truncated and notched at its summit, so as to present a two-lobed appearance, and the two lower are rounded at the base and usually pointed. In the larger leaves, the lateral lobes have each a tooth-like projection at some distance below their apex. This peculiar form of the leaf serves to distinguish the tree from all others inhabiting the American forests. On isolated trees the flowers are very numerous. They are large, beautifully variegated with different colors, among which yellow predominates, and in appearance bear some resemblance to the tulip, which has given a name to the species. Each flower stands on a distinct terminal peduncle. The calyx is double, the outer two-leaved and deciduous, the inner consisting of three large, oval, concave leaves, of a pale green color. The corolla is composed of six, seven, or more obtuse, concave petals. The stamens are numerous, with short filaments and long linear anthers. The pistils are collected into the form of a cone, the upper part of which is covered with minute stigmas. The fruit consists of numerous long, narrow scales, attached to a common axis, imbricated in a conical form, and containing each two seeds, one or both of which are often abortive. The bark was the portion formerly official. It is taken for use indiscriminately from the root, trunk, and branches, though that of the root is thought to be the most active.

Deprived of the epidermis, it is yellowish white, the bark of the root being somewhat darker than that of the stem or branches. It is very light and brittle, of a feeble, rather disagreeable odor, strongest in the fresh bark, and of a bitter, pungent, and aromatic taste. These properties are weakened by age, and we have found specimens of the bark, long kept in the shops, almost insipid. The late Prof. Emmet, of the University of Virginia, believed that he had isolated the active principle, and gave it the name of *liriodendrin*. It was white, crystallizable, brittle, insoluble in water, soluble in alcohol and ether, fusible at 82·2° C. (180° F.), volatilizable and partly decomposed at 132·2° C. (270° F.), of a slightly aromatic odor, and a bitter, warm, pungent taste. It does not unite either with acids or with alkalies; and the latter precipitate it from the infusion of the bark by combining with the matter which renders it soluble in water. Water precipitates it from its alcoholic solution. It is obtained by macerating the root in alcohol, boiling the tincture with magnesia till it assumes an olive-green color, then filtering, concentrating by distillation till the liquid becomes turbid, and finally precipitating the liriodendrin by the addition of cold water. (*A. J. P.*, iii. 5.) Mr. J. U. Lloyd believes that liriodendrin is really an alkaloid, to which he gives the name of *tuliperine*, and this, according to Prof. Bartholow, appears to possess toxic properties. (*Pharm. Rundschau*, 1886, 169.) The virtues of the bark are extracted by water and alcohol, but are injured by long boiling.

Liriodendron is a stimulant tonic, with diaphoretic properties, which has been used in chronic *rheumatism* and *dyspepsia*. Dose of bark in powder, from half a drachm to two drachms (1·94–7·7 Gm.); of saturated tincture, a fluidrachm (3·88 C.c.).

LITHOSPERMUM OFFICINALE. L. *Gromwell. Milium Solis.* A European perennial

of the nat. ord. Boraginaceæ, the seeds of which are ovate, of a grayish-white or pearl color, shining, rather larger than millet-seeds, and of a stony hardness, from which the generic name of the plant originated. They were formerly used as stimulant diuretics, but are nearly inert.

LITMUS. LACMUS. *Turnsole. Tournesol. Lacca Cœrulea. Lacca Musica. Laquebleu*, Fr. *Lackmus*, G. This is a peculiar coloring matter derived from *Roccella tinctoria*, D. C., and other lichens. Three purple or blue coloring substances are known in commerce, obtained from lichenous plants. They are called severally *litmus*, *orchil*, and *cudbear*. The lichens employed are different species of *Roccella*, *Lecanora*, *Variolaria*, and others. They grow on alpine or maritime rocks, in various parts of the world, and for commercial purposes are collected chiefly upon the European and African coasts and the neighboring islands, as the Azores, Madeira, Canaries, and Cape Verde. The particular species most employed are probably *Lecanora tartarea* or *Tartarean moss*, growing in the north of Europe, and *Roccella tinctoria* or *orchilla weed*, which abounds upon the African and insular coasts, and is called commercially, in common with other species of the same genus, *Angola weed*, *Canary weed*, etc., according to its supposed nativity.

The principles in these plants upon which their valuable properties depend are themselves colorless, and yield coloring substances by the reaction of water, air, and ammonia. They are generally acids or acid anhydrides, and are named *lecanoric*, *orsellic*, *erythric*, etc., according to their origin. Lecanoric (diorsellinic) acid, $C_{16}H_{14}O_7$, the original constituent of most of these plants, when boiled with water or alkaline solutions, is changed into *orsellinic acid*, as follows: $C_{16}H_{14}O_7 + H_2O = (C_8H_8O_4)_2$. *Orsellinic acid*, $C_6H_2\begin{cases}CH_3\\(OH)_2\\COOH,\end{cases}$ fuses at 176° C. (348·8° F.), and decomposes into *orcin*, $C_6H_3(CH_3)(OH)_2$, and CO_2. The same decomposition is readily effected by distillation with milk of lime. Orcin combines with ammonia gas to form $C_8H_8O_2,NH_3$, the solution of which exposed to the air becomes colored reddish by the formation of *orcëin*, $C_7H_7NO_3$. This latter compound forms the basis of the commercial *orseille* extract (*orchil* or *archil*).

Kane (*Watt's Dictionary*, vol. iii. 731) described a deep red crystalline substance, *erythrolitmin*, and a brownish-red coloring principle, *azolitmin*, $C_7H_7NO_4$. This latter is considered as the distinctive coloring matter of the commercial litmus. It is nearly insoluble in cold water or benzene, but dissolves in alcohol with red, and in ether with yellow color. It appears to have the characters of a weak acid, the salts of which are blue and the potassium compound of which exists in litmus.

To test the value of the plants as dye-stuffs, they may be macerated in a weak solution of ammonia, or a solution of calcium hypochlorite may be added to their alcoholic tincture. In the former case a rich violet-red color is produced; in the latter, a deep blood-red color instantly appears, but soon fades.

Lacmus or *litmus* is prepared chiefly if not exclusively in Holland. The process consists in macerating the coarsely powdered lichens, in wooden vessels under shelter, for several weeks, with occasional agitation, in a mixture of urine, lime and potash or soda. A fermentation ensues, and the mass, becoming first red and ultimately blue, is after the last change removed, mixed with calcareous or silicious matter to give it consistence, and with indigo to deepen the color, and then introduced into small moulds, where it hardens. It comes to us in rectangular cakes, from a quarter of an inch to an inch in length, light, friable, finely granular, of an indigo-blue or deep violet color, and scattered over with white saline points. It has the combined odor of indigo and violets, tinges the saliva of a deep blue, and is somewhat pungent and saline to the taste. From most vegetable blues it differs in not being rendered green by alkalies. It is *reddened by acids*, and restored to its original blue color by *alkalies*.

Its chief use in medicine is as a test of acids and alkalies. For this purpose it is employed either in infusion or in the form of litmus-paper. The infusion, usually called *tincture of litmus*, may be made in the proportion of one part of litmus to twenty of distilled water, and two parts of alcohol may be added to preserve it. *Litmus-paper* is prepared by first forming a strong clear infusion with one part of litmus to four of water, and dipping slips of white unsized paper into it, or applying it by a brush to one surface only of the paper. The paper should then be carefully dried, and kept in well-stoppered vessels, from which the light is excluded. It should have a uniform blue or slightly purple color, neither very light nor very dark. As a test for alkalies the paper may be stained with an infusion of litmus previously reddened by an acid, care being taken to avoid all excess. By gas-light it is said that the change of color cannot be determined by the eye exactly, as the blue of litmus becomes mauve; but this may be obviated by watching the process through a green glass, by which the faintest trace of blue becomes discernible. (*P. J. Tr.*, 2d ser., vi. 479.)

Orchil or *archil* (*Orseille*, Fr., G.), as prepared in England, is in the form of a thickish liquid, of a deep reddish-purple color, but varying in the tint, being in one variety redder than in another. The odor is ammoniacal. It is made by macerating lichens in a covered wooden vessel, with an ammoniacal liquor, either consisting of stale urine and lime, or prepared by distilling an impure salt of ammonia with lime and water. (Pereira.) For details as to the method of preparation, see *Chemical News*, 1874, 143. It is occasionally adulterated with the extracts of colored woods, as logwood, sappan-wood, etc. A mode of detecting these adulterations is given by Mr. F. Leeshing in the *Chem. Gaz.* of June 1, 1855, 219.

Cudbear (*Orseille de terre*, Fr.; *Persio*, G.) is in the form of a purplish-red powder. It is procured in the same manner as orchil; but the mixture, after the development of the color, is dried and pulverized.

The point in which the preparation of these coloring substances differs from that of litmus appears to be, that potash or soda is added, in the latter, to the ammoniacal liquid used. Orchil and cudbear are employed as dye-stuffs, and sometimes, in like manner, with litmus, as a test of acids and alkalies. For some practical applications, see *A. J. P.*, 1874. For chemical constituents of lichens, see *A. J. P.*, 1898, 455.

LOCO PLANTS. *Crazy Weeds.* These are plants growing in the far-western States, the eating of which by horses and cattle is believed to produce loss of flesh, disordered vision, delirium, convulsive

movements, or stupor and death. Much doubt hangs about the matter, but *Astragalus mollissimus*, Torr., is believed to be the loco of Kansas, whilst *A. drummondii*, Dougl., is the loco plant of Colorado. Prof. O'Brien, of the State Agricultural College of Colorado, has examined six species of the astragalus, including those mentioned, and in none of them has any alkaloid, resin, or other active chemical substance been found. This is in conformity with the fact that the Western astragalus, believed to be *A. mollissimus*, Torr., was carefully tested by Dr. H. C. Wood upon rabbits and dogs, and found not to be poisonous, a result which has been confirmed by Jas. Kennedy, *Pharm. Rec.*, July, 1888; by Ingersoll, *Proc. A. P. A.*, 1890; and by L. E. Sayre, *Proc. A. P. A.*, 1888. On the other hand, Dr. Isaac Ott found a plant, which he believed to be *A. mollissimus*, to act as a violent spinal poison and mydriatic. (*New Remedies*, Aug. 1882.) According to Dr. Carl Ruedi, the decoction produces in the rabbit great hilarity, excitement, and even ferocity, and contains an alkaloid, *locoin*, and an acid. (*Trans. Colorado State Med. Soc.*, 1895.) President Ingersoll, of the Colorado State Agricultural College, at the post-mortem examination of a number of "locoed sheep," found in each animal masses of *Tænia expansa*, and believes that this tape-worm was the cause of the illness. There can be no doubt that domestic animals are destroyed in the West in very large quantities from an affection which is known as "loco," and hundreds of thousands of dollars have been spent in bounties by the State of Colorado for the extirpation of the supposed poisonous astragalus. But the cause of the disorder remains obscure. The most probable explanation of the case is that the fermentation of the plants in the intestines of the animal develops a poison which is absorbed, and that we have in the loco disease one parallel to the "Lathyrismus" of Europe. (See also *New York Med. Journ.*, 1889, xlix.)

LOLIUM TEMULENTUM. L. *Darnel. Bearded Darnel. Ivraie*, Fr. *Lolch, Taumelkorn*, G. One of the Gramineæ or grasses, indigenous in the Old World, but introduced into the United States, and owing its chief importance to the circumstance that it is apt to grow among wheat and other grains, and thus sophisticate the product with its seeds. From ancient times, these have been supposed to be deleterious to the human system, producing symptoms analogous to intoxication from alcoholic drinks, whence the plant derived its specific name of *temulentum*, and the French name of *ivraie*. The seeds have a sweetish taste, and are said to contain gluten, starch, and sugar; and there is nothing in their sensible properties which would suggest the idea that they might be poisonous. Indeed, De Candolle states that they are often eaten in bread without inconvenience; and that a beer into which they enter as an ingredient is drunk with impunity. (*Mérat and De Lens*, iv. 141.) The testimony, however, to the fact that they produce vertigo, dizziness, headache, sleepiness, and a species of drunkenness is too strong to be resisted; though very few instances, so far as we know, have been recorded of death from their use. MM. Rivière and Maizière have each recorded a fatal case, which occurred in peasants who had for several days lived upon bread consisting to the extent of two-thirds or five-sixths of darnel. (*Journ. de Pharm.*, 1863, 280.) Though thus acting on man, dogs, sheep, and horses, the seeds are said to be wholly innoxious to hogs, cows, and ducks; and poultry have even been fattened by them. The remedy, in case of poisoning, would be as soon as possible to evacuate the stomach. Lindley states that this is the only one of the grasses which has been satisfactorily proved to have deleterious properties. (*Med. and Economic Bot.*, 27.) Dr. P. Antze (*A. J. P.*, 1891, 568) announced the discovery of two alkaloids, *loliine*, which is volatile, and a solid base, *temulentine*. A more recent careful analysis of the seeds by Hofmeister (*A. J. P.*, 1892, 611) corrects these results. He finds that the volatile alkaloid "loliine" was impure ammonia; that the so-called "temulentine" was a mixture containing some of the narcotic principles which Hofmeister isolated and called *temuline*. Hofmeister's temuline is not crystallizable, is soluble in water, has an alkaline reaction, and forms a crystallized hydrochlorate with the formula $C_7H_{12}N_2O.2HCl$. The author also found an acid containing nitrogen and an uncrystallizable alkaloidal body. Dr. P. Antze found that both *loliine* and *temulentine* are poisonous, causing violent gastro-intestinal irritation, dyspnœa, and general depression. (*Centralb. für die Gesammte Therap.*, 1891.)

LONICERA CAPRIFOLIUM. L. *Honeysuckle.* (Nat. ord. Caprifoliaceæ.) This ornament of our gardens is a native of the south of Europe. Its sweet-scented flowers are sometimes used in perfumery, and a syrup prepared from them has been given in *asthma* and other pectoral affections. The expressed juice of the plant has been recommended for the stings of bees, being rubbed directly on the injured spot. The fruit of all the species of Lonicera is said to be emetic and cathartic (Mérat and De Lens), and that of *L. xylosteum* (L. ?) to have caused serious poisoning. (*Journ. de Pharm.*, 4e sér., xviii. 65.)

LORETIN. *Meta-iodo-ortho-oxyquinoline-ana-sulphonic Acid.* $C_9H_4IN.OH.SO_3H$. This organic iodine compound, discovered by Claus, of Freiburg, is a bright yellow, odorless, crystalline powder, insoluble in ether and oils, soluble in from 1 to 2 parts in 1000 in cold water, 5 to 6 parts in 1000 in boiling water; forms neutral soluble salts with sodium, potassium, ammonium, and magnesium, yielding a deep, orange-yellow solution. It is very stable for an iodine compound, not being affected by exposure to direct sunlight. It has been found by Ammelburg to be as a germicide much more powerful than iodoform, with seven different pathogenetic germs essayed. Given hypodermically to guinea-pigs (5 C.c. of a 5 per cent. solution for long periods), it produced no poisoning, and no iodine could be detected in the urine. (*Deutsche Zeitsch. für Thiermed. und Vergleich. Path.*, 1894.)

It has been especially commended as a substitute for iodoform by Schinsinger and by Snow. (*Brit. Med. Journ.*, ii. 1895.) It may be used as a dusting powder alone or mixed with calcined magnesia or starch; as collodion, from 2 to 10 per cent.; as ointment, 5 to 10 per cent.; and in solution, 1 to 2 per cent. of the soluble sodium salt. The soluble calcium salt *calcium loretin* has been especially recommended for the manufacture of antiseptic gauze. Snow states that the pure powder may be used without danger of poisoning or of local irritation.

LOSOPHAN. *Tri-iodo-meta-cresol*, $C_6HI_3(OH)(CH_3)$, contains 78·39 per cent. iodine, and

is prepared by the action of iodine upon m-oxy-toluic acid in the presence of a definite quantity of alkali, in the same manner that tri-iodo-phenol may be obtained from salicylic acid. It crystallizes in white needles, melting at 121·5° C., soluble with difficulty in alcohol, but readily in ether, benzin, and chloroform. Losophan has been recommended by Dr. Saalfeld in parasitic skin diseases and in chronic *eczema* and *prurigo*, but J. A. Cantrell, after extended trial, concludes that it is without therapeutic value. It may be employed either as a 1 or 2 per cent. solution in three parts alcohol and one part water, or as a 1 to 10 per cent. ointment with vaseline or four parts lanolin and one part vaseline.

LUCUMA. This Brazilian genus of the nat. ord. Sapotaceæ yields a number of species, which are used in Brazil as medicines or articles of diet. For an account of them, see *Pharm. Rundschau*, 1888. See also *Monesia.*

LUFFA. *Luffa Ægyptiaca. Vegetable Sponge. Wash-rag Sponge. Gourd Towel.* A cucurbitaceous genus, indigenous to Arabia and Egypt, furnishing a gourd-like fruit, which presents upon the removal of the epidermis a durable skeleton of interwoven woody fibres, which are used in place of sponge. (*A. J. P.*, 1884, 6.) The fruit of *L. echinata*, Roxb., of India, is a violent irritant poison, from which C. J. H. Warden has separated a principle allied to, if not identical with, *colocynthitin.* (*P. J. Tr.*, June, 1890.)

LUPINUS ALBUS. L. *Lupin. Lupin*, Fr. *Feigbohne, Wolfsbohne*, G. A plant belonging to the Leguminosæ, and a native of Europe and Western Asia, which is sometimes cultivated in our gardens. Other species are also met with,—*L. hirsutus*, L., *L. luteus*, L., *L. polyphyllus*, Lindl., *L. densiflorus*, Benth. The last two are indigenous to the Pacific slope and the West. The bitter principle *lupinin*, $C_{26}H_{32}O_{16}$, is a glucoside, and its solution in alkalies is of a dark brownish-yellow color. On boiling with dilute acids it is decomposed into *lupigenin*, $C_{17}H_{12}O_6$, and a fermentable, dextro-rotatory glucose. The bruised seeds of white lupin, after soaking in water, are sometimes used as an external application to *ulcers*, etc., and internally are said to be anthelmintic, diuretic, and emmenagogue. An instance has been recorded where a decoction used as an injection in the rectum caused symptoms which suggested a poisonous character for the drug. Schulze and Steiger have isolated an alkaloid, *arginine*, $C_6H_{14}N_4O_2$, from the germinated seeds of *Lupinus luteus.* (*A. J. P.*, 1887, 428.) Steiger (*Journ. Soc. Chem. Indus.*, 1886, 385) has also studied a carbohydrate analogous to dextrin, which Baeyer and Eichborn discovered in *Lupinus luteus.* He finds that it is not changed by yeast, that nitric acid converts it into mucic acid, and that dilute sulphuric or hydrochloric acid converts it into galactose.

LYCETOL. *Dimethylpiperazine Tartrate.* $NH(CH_2CHCH_3)_2NH + H_2C_4H_4O_6$. This is the tartrate of a substitution product from piperazine, in which an atom of hydrogen in each of two CH_2 groups is replaced by the methyl group CH_3. Lycetol is a white powder melting at 243° C., readily soluble in water, having a taste which is described as pleasant and acidulous. It is asserted that it is an active diuretic, exerting a powerful solvent influence upon uric acid, and causing no disturbance of digestion even when given continually in large doses. According to Hamonic, it acts very favorably in purulent *cystitis*, lessening suppuration and the tendency to decomposition of the urine. It has been used with asserted excellent results in chronic and acute gout and in various other forms of uric acid diathesis, as well as for solution of *calculi.* Dose, from fifteen to thirty grains (0·9–1·9 Gm.) daily, administered in from one to two pints of water.

LYCIUM BARBARUM. L. *Matrimony Vine.* The genus Lycium belongs to the Solanaceæ. Different species have been used in various parts of the world in reference to supposed medical virtues. *Lycium barbarum*, L., which is indigenous in the south of Europe and in Asia, is a thorny shrub, with long flexible branches, and is cultivated for hedges and arbors. Husemann and Marmé found in the leaves and stem an alkaloid, *lycine*, $C_5H_{11}NO_2$. (*A. J. P.*, 1864, 226.) It is characterized by its strong affinity for water, which causes it to deliquesce in a few minutes after exposure, and renders it very soluble in that liquid. It is also readily soluble in alcohol, but nearly insoluble in ether. It is crystallizable, of a sharp but not bitter taste, and forms crystallizable salts with the acids. Prof. Aug. Husemann believes that lycine does not exist in the plant, but is formed during the process of extraction, and also that it is identical with *betaine*, $C_5H_{11}NO_2$, the alkaloid obtained from beet-juice by Scheibler, and with the oxyneurine of Liebreich. (*A. J. P.*, xlvii. 209.) E. Schmidt found in *Lycium barbarum* traces of mydriatic alkaloids resembling those of belladonna. (*Apoth. Zeit.*, 1890, 511.) The young shoots of one of the species of Lycium are eaten in Spain as asparagus, and its leaves as salad; and the aborigines of Colombia used another species against *erysipelas.* The leaves of *L. barbarum*, as well as the fruit, are said to be used by the physicians of Japan. (Mérat and De Lens.)

LYCOCTONA. For its physiological action, see *Phil. Med. Times*, Oct. 1875.

LYCOPODIUM SAUSSURUS. *Piligan.* In this Brazilian lycopod Adrian has found an alkaloid, *piliganine* (*Compt.-Rend.*, June, 1886), which is said to act upon animals as a powerful emetic, cathartic, and convulsant. (See also *Bull. Thérap.*, cxi. 174.)

LYCOPUS. *U. S.* 1870. *Lycopus Virginicus*, L. *Lycope de Virginie*, Fr. *Virginischer Wolfsfuss*, G. The *bugle-weed* is an indigenous labiate herb, with a perennial creeping root, which sends up an erect, nearly simple, obtusely quadrangular stem, from twelve to eighteen inches high, and furnished with opposite sessile leaves. These are broad-lanceolate, attenuated and entire at both extremities, remotely serrate in the middle, somewhat rough, purplish, and beset with glandular dots on their under surface. The flowers are minute, in small axillary whorls, with two small subulate bracts to each flower, and a white corolla. The seeds are longer than the calyx, which is spineless. This plant grows in shady and wet places throughout the greater part of the United States. Its flowering period is August. The whole herb is used. Jos. L. Weil found 0·41 per cent. of a fat melting at 50° C., 0·68 per cent. of a granular wax melting at 70° C., 0·43 per cent. of a crystallizable resin soluble in ether, a crystallizable glucoside, and a small quantity of gallic acid and tannin. (*A. J. P.*, 1890, 72.) It has a peculiar odor and a nauseous

slightly bitter taste, and imparts these properties, as well as its medical virtues, to boiling water.

According to A. W. Ives, the bugle-weed is a mild narcotic. It is said also to be astringent, and has been employed with asserted success in pulmonic and other hemorrhages. Dose of infusion (℥i to Oi boiling water), from half a pint to one pint daily.

Lycopus europæus, L., is said to be frequently collected and sold for *L. virginicus*. The former may be distinguished by its acutely quadrangular stem, its narrow lanceolate leaves, of which the lower are somewhat pinnatifid, its more crowded flowers, and the acute segments of its calyx, armed with short spines. It has been employed in Europe as a substitute for quinine.

LYSIDINE. Lysidine is a reddish-white, crystalline substance, having a peculiar nauseous taste suggesting the odor of mice. On account of its great hygroscopicity it is now supplied to the trade in a uniform 50 per cent. solution. It was brought forward by Prof. Ladenburg as a solvent for uric acid, with the statement that it had five times the power of piperazine. Reports had been made upon it by Grawitz (*Deutsch. Med. Wochensch.*, 1894) and by Woodcock Goodbody (*Brit. Med. Journ.*, ii. 1896). It is asserted that the solvent action of this and also of piperazine is exerted in the blood, so that the uric acid is taken up from the tissues of the body more thoroughly than is ordinarily done. Goodbody believes that lysidine is more active as a diuretic than is piperazine. From ten to twenty grains (0·6–1·3 Gm.) may be given three times a day in a half-pint of aerated water We have used it in our cases with apparent good results.

LYTHRUM SALICARIA. L. *Loosestrife. Purple Willow-herb. Salicaire*, Fr. *Röther Weiderich*, G. This is an elegant perennial plant of the nat. ord. Lythraraceæ, a native of Europe, but naturalized from Ontario to Kentucky and Arkansas. The whole herbaceous part is medicinal, and is dried for use. In this state it is inodorous, and has an herbaceous, somewhat astringent taste. It renders boiling water very mucilaginous, and its decoction is blackened by the sulphate of iron. Loosestrife is demulcent and astringent, and may be advantageously given in *diarrhœa* and chronic *dysentery*, after due preparation by evacuating treatment. It has long been used in Ireland in these complaints, and is said to be a popular remedy in Sweden. The dose of the powdered herb is about a drachm two or three times a day. A decoction of the root, prepared by boiling an ounce in a pint of water, may be given in the dose of two fluidounces.

MACALLO or YABA BARK. For an article on this Yucatan bark, see *A. J. P.*, 1879, 392.

MACKAY BEAN. This is the seed of *Entada scandens*, Benth. (nat. ord. Leguminosæ), of Queensland, which has the reputation in the colony of being strongly poisonous, and in which John Moss found saponin. (*P. J. Tr.*, vol. xviii. 242.)

MACLURA AURANTIACA. Nutt. (Now *Toxylon pomiferum*, Raf.) (Nat. ord. Moraceæ.) The bark of the root of this tree, which is indigenous in our Southern States, is said to be considerably used in making a yellow dye. Alex. King has found in it *moric* and *morintannic acids*. (*A. J. P.*. xlvi. 257.)

MAGNESII ACETAS. *Magnesium Acetate.* $Mg(C_2H_3O_2)_2$. This salt has been used as a substitute for the citrate, but is much inferior. For further information, see previous editions *U. S. D.*

MAGNESII CHLORIDUM. *Magnesium Chloride.* $MgCl_2$. This is produced at Stassfurt in the Stassfurt potash and bromine industries. When a concentrated solution of this salt is evaporated to dryness, it is partially decomposed into magnesia and hydrochloric acid, the latter being evolved. By a careful evaporation, stopping it so soon as the vapor begins to redden litmus-paper, the chloride may be obtained in the state of a fused hydrate, having the composition MgCl,6HO. Or, by adding ammonium chloride to the solution, the mixed chlorides can be evaporated to dryness, and the sal-ammoniac volatilized without decomposing the magnesium chloride. Dr. Lebert finds this bitter and very deliquescent salt to act mildly and favorably as a purgative, producing a flow of bile and an increase of appetite. On account of its extreme deliquescence, he recommends it in the liquid form, prepared by dissolving the salt in its weight of water. Dose, an ounce (31·1 Gm.) sufficiently diluted to an adult, and half an ounce (15·55 Gm.) to a child ten years old. (*Arch. Gén.*, 4e sér., iii. 448.)

MAGNESII SALICYLAS. *Magnesium salicylate* has been enthusiastically recommended by Huchard in *typhoid fever*, given in daily doses of from fifty to one hundred grains (3·2–6·5 Gm.) continuously; diarrhœa is not a contraindication to its use. According to B. Fischer (*Pharm. Zeit.*, 1888, 146), the salt is prepared by dissolving salicylic acid in boiling water, saturating the solution with magnesium carbonate, filtering, and crystallizing. It forms long, colorless hygroscopic needles, is readily soluble in water and alcohol, and has a somewhat bitter taste. (*A. J. P.*, 1888.)

MAGNESII SULPHIS. *U. S.* 1880. *Sulphite of Magnesium.* ($MgSO_3.6H_2O$.) This salt may be prepared by double decomposition between magnesium sulphate and neutral sodium sulphite. Owing to the almost universal presence of sulphate in the sodium sulphite, Jos. P. Remington proposes to prepare it by suspending eight parts of pure magnesia in sixteen parts of water, and then adding gradually, with stirring, official aqueous sulphurous acid in excess. The crystals which form are washed with very cold water, drained, and dried. (*A. J. P.*, xl. 97.) "A white, crystalline powder, gradually becoming oxidized on exposure to air, odorless, having a slightly bitter, somewhat sulphurous taste, and a neutral or slightly alkaline reaction. Soluble in twenty parts of water at 15° C. (59° F.), and in nineteen parts of boiling water; insoluble in alcohol. When heated to 200° C. (392° F.), the salt loses its water of crystallization (50·9 per cent.), and is converted into magnesia and anhydrous sulphate of magnesium. The aqueous solution of the salt, mixed with chloride of ammonium, yields, with excess of test-solution of phosphate of sodium and water of ammonia, a white, crystalline precipitate soluble in acids. When treated with four times its weight of diluted hydrochloric acid, the salt dissolves completely and emits the odor of burning sulphur, without becoming cloudy (difference from hyposulphite). A 1 per cent. aqueous solution, strongly acidulated with hydrochloric acid, should not afford more than a slight cloudiness with test-solution of chloride of barium (limit of sulphate)." Magnesium sulphite shares the general medical properties of the sul-

phites, but is better fitted for internal administration on account of its less solubility and less disagreeable taste, etc. (See *Sodii Sulphis.*) The dose is from fifteen grains to half a drachm (1–2 Gm.).

MAGNESIUM SILICATE. *Hydrated Magnesium Silicate. Meerschaum.* $H_2Mg_2Si_3O_9+H_2O$. This is a mineral used for the manufacture of tobacco-pipes. It was brought into notice as a medicine by Garraud, who used it successfully as a substitute for bismuth subnitrate in obstinate *diarrhœa.* Trousseau employed it also with great success in numerous cases of diarrhœa. It is reduced to fine powder, and given in doses of from one to four drachms a day. It no doubt acts mechanically, either as an absorbent or a protective of the intestinal coats. (*Journ. de Pharm.*, 4e sér., iii. 385.)

MAGNOLIA. *U. S.* 1880. *Magnolia Bark. Ecorce de Magnolier*, Fr. *Magnolienrinde*, G. (Nat. ord. Magnoliaceæ.) Three species of magnolia were formerly official, as follows: 1. *Magnolia glauca*, L. (now *M. virginiana*, L.), which in the Northern States is often nothing more than a shrub, sometimes attains in the South the height of forty feet. The leaves are scattered, petiolate, oval, obtuse, entire, glabrous, thick, opaque, yellowish green on their upper surface, and of a beautiful pale glaucous color beneath. The flowers are large, terminal, solitary, cream-colored, strongly and gratefully odorous, often scenting the air to a considerable distance. The calyx is composed of three sepals; the petals, from eight to fourteen in number, are obovate, obtuse, concave, and contracted at the base; the stamens are very numerous, and inserted on a conical receptacle; the germs are collected into a cone, and each is surmounted by a linear recurved style. The fruit is conical, about an inch in length, consisting of numerous imbricated cells, each containing a single scarlet seed. This escapes through a longitudinal opening in the cell, but remains for some time suspended from the cone by a slender thread.

M. glauca is found along the seaboard of the United States, from Cape Ann, in Massachusetts, to the shores of the Gulf of Mexico. It is abundant in the Middle and Southern States, usually growing in swamps; but is seldom met with in the interior, west of the mountains. It begins to flower in May, June, or July, according to the latitude. It is usually known as *magnolia* in the North, and as *white bay* or *sweet bay* in the South, but is occasionally called *swamp sassafras*, *beaver-tree*, etc.

2. *M. acuminata*, L., is much larger than the preceding, often growing to the height of seventy or eighty feet. The leaves are six or seven inches long by three or four in breadth, oval, acuminate, and pubescent on their under surface. The flowers are five or six inches in diameter, bluish or cream-colored, slightly odorous, with obovate rather obtuse petals from six to nine in number. The tree grows in the interior mountainous regions of the United States, extending along the Alleghanies from New York to their termination in Georgia, and seldom existing in the low country far either to the east or west of that range. It is called *cucumber-tree.*

3. *M. tripetala*, L., is a small tree, sometimes, though rarely, reaching an elevation of thirty feet, and almost always having an inclined trunk. It is remarkable for the size of its leaves and flowers. The former are eighteen or twenty inches long by seven or eight in breadth, thin, obovate, somewhat wedge-shaped, entire, acute at both extremities, pubescent when young, and often disposed in rays at the extremity of the shoots, displaying a surface thirty inches in diameter. Hence has arisen its name of *umbrella-tree.* The flowers are terminal, seven or eight inches in diameter, white, with from five to twelve oval acute petals, of which the three outer are reflexed. This species extends from Northern New York to the southern limits of the United States. It is found only in shady situations with a deep and fertile soil. Wallace Procter found in the fruit a crystalline principle. When pure, this is without smell, and has at first little taste, in consequence of its insolubility in the liquids of the mouth, but after a time produces an irritant effect on the fauces. It is nearly insoluble in cold, but slightly soluble in hot water, very soluble in alcohol, ether, chloroform, carbon disulphide, and benzin. It is neutral to test-paper. Procter considered it analogous to the liriodendrin obtained by Emmet, but quite distinct. He proposed for it the name of *magnolin*, which is the more appropriate, as the principle seems to be the same as that obtained by Stephen Procter from the bark of *M. grandiflora*, and by W. D. Harrison from that of *M. glauca.* (*A. J. P.*, xxxiv. 29.) For a more detailed account of it, see *A. J. P.*, 1872, 145; also Lloyd's paper in *Pharm. Rundschau*, 1866, 224. W. F. Rawlins (*A. J. P.*, 1889, 7) obtained from the leaves of the *M. glauca* a small quantity of a volatile oil of bright green color, with an odor resembling fennel or anise, but more pleasant. From the ethereal solution of this oil small crystals deposited. Indications were also had of a bitter glucosidal principle.

The bark and fruit of all the species of Magnolia are possessed of similar medicinal properties; but the bark only was official, and that of the root has been thought to be most efficient. "The bark from young wood is quilled or curved, thin, externally orange-brown and glossy, or light gray, with scattered warts and somewhat fissured, internally whitish or pale brownish and smooth; fracture short, in the inner layer somewhat fibrous; inodorous; taste somewhat astringent, pungent, and bitter. The bark of old wood, deprived of the cork, is whitish or brownish, fibrous, and less pungent." *U. S.* 1880. The aromatic property, which resides in a volatile principle, is diminished by desiccation, and entirely lost when the bark is long kept. The bitterness, however, remains. The bark is destitute of astringency. The bark of *Magnolia grandiflora* was found by Stephen Procter to contain volatile oil, resin, and a principle analogous to the liriodendrin of Prof. Emmet. (*A. J. P.*, xiv. 95.)

Magnolia is a gently stimulant aromatic tonic and diaphoretic. It has been used in *malaria* and in *rheumatism.* The dose of the recently dried bark in powder is from half a drachm to a drachm (1·95–3·9 Gm.), frequently repeated. Diluted alcohol extracts all the virtues of the medicine; and a tincture, made by macerating the fresh bark or fruit in brandy, is a popular remedy in chronic rheumatism.

MALAKIN. *Salicyliden-paraphenetidine.* $C_6H_4\begin{cases}OC_2H_5\\N:CH.C_6H_4(OH)\end{cases}$. This occurs in small, bright yellow, fine needles, melting at 92° C., insoluble in water, sparingly soluble in cold, but quite so in hot alcohol, insoluble in carbonates of the

alkalies, but soluble with a yellow color in soda lye; weak mineral acids decompose it, forming salicyl-aldehyde and paraphenetidine.

Malakin contains about 50 per cent. of salicyl-aldehyde, and in 1893 Jacquet called attention to it as an anti-rheumatic remedy, stating that it is decomposed in the stomach, yielding salicyl-aldehyde to the blood, and offering, therefore, a method of giving salicylic acid. Cases have been reported not only by Jacquet, but by Merkel, by Korotkoff, by Oussoff, by Abernethy, and others, in which, in doses of from forty-five to ninety grains a day, malakin acted very favorably in acute rheumatism. On the other hand, Ottolenghi (*Therap. Wochensch.*, ii. 1895) has found that after the administration of malakin, crystals of it can be found throughout the whole intestines, even as low as the rectum, so that the decomposition and after-absorption of it must be exceedingly slow and uncertain; and the contention of Bauer, that it is distinctly inferior to the older salicylates, is in all probability correct. Ottolenghi suggests that malakin must act on tænia and other intestinal parasites, and may therefore prove useful as an anthelmintic.

MALAMBO or MATIAS BARK. A bark received from South America by Alex. Ure, under the name of *matias bark*, was found to have the characters of the *malambo bark*, which is held in high esteem in Colombia, where it is produced. According to H. Karston, it is derived from a hitherto undescribed species of Croton, which he names *Croton Malambo*. (See *Floræ Colombiæ Terrarumque adjacentium Specimina Selecta.*) This is a small tree or shrub, growing on the coast of Venezuela and Colombia. (*P. J. Tr.*, 1859, 321.) The bark is described by Ure as being three or four lines thick, brittle, though somewhat fibrous, of a brown color, and covered with an ash-colored tuberculous epidermis. It has an aromatic odor and a bitter pungent taste, and yields these properties to water and alcohol. Its active ingredients appear to be a volatile oil and a bitter extractive matter. According to Mackay, it has been used successfully in *intermittents*, convalescence from continued fevers, *hemicrania*, *dyspepsia*, and other cases in which tonic remedies are useful, and also as an adjuvant to diuretics. It is probably nothing more than an aromatic tonic. Ure has administered it with good effect as a substitute for Peruvian bark. (*P. J. Tr.*, iii. 169.)

Under the name of *Winter's bark*, a considerable quantity of bark was some time since imported into the United States from South America, which E. S. Wayne, of Cincinnati, has identified with the malambo bark above described, having found it to correspond with that product both in sensible characters and composition. (*A. J. P.*, xxix. 1.) George B. Wood confirmed this decision of Wayne; a specimen in his possession answered precisely to the description given by Ure. The malambo bark, analyzed by Cadet de Gassicourt, yielded volatile oil, bitter resin, and extractive, but no tannic or gallic acid, and no alkaloid; and the same was the case with the so-called Winter's bark examined by Wayne. (*Ibid.*) The same bark has been analyzed by F. B. Dancy, who found in it volatile oil, gum, starch, albumen, resin, extractive, fixed oil, wax, and several inorganic substances. (*Ibid.*, 219.)

MALOUETIA NITIDA. *Spruce. Guachamacà.* (Nat. ord. Apocynaceæ.) This plant, of Venezuela, contains an alkaloid, *guachamacine*, which Kobert believes to be identical with *curarine*. (*A. J. P.*, 1885, 560.)

MALTUM. *U. S.* 1880. *Malt. Maltum Hordei*, L. *Barley Malt. Malt d'Orge, Drêche*, Fr. *Gerstenmalz*, G. "The seed of *Hordeum distichum*, Linné (nat. ord. Graminaceæ), caused to enter the incipient stage of germination by artificial means, and dried," *U. S.* 1880. The object of malting is to allow germination of grain to go just far enough to develop the maximum amount of *diastase*, the ferment by which the starch is converted into sugar. In order to achieve this, the barley is: first, *steeped*,—*i.e.*, allowed to remain one or two days in cold water, of which it absorbs from 10 to 50 per cent.; second, *couched*,—*i.e.*, thrown into heaps upon a floor and allowed to develop heat and germinate; third, when the *acrospire* or shoot is one-third the length of the grain, the latter is *floored*,—*i.e.*, spread upon wide floors to dry; fourth, *kiln-dried*,—*i.e.*, exposed to such a temperature as thoroughly to dry it and to kill the young plant. If the temperature be raised high enough to scorch the grain, it becomes *Amber Malt*, or *Black Malt*, according to the extent of the charring, and porter owes its dark color to the blackening of the malt.

The so-called malt liquors are prepared by making an infusion (*wort*) of the bruised malt, adding hops and various other substances, and fermenting. *Ale*, *brown stout*, and *porter* are made by rapid fermentation at a comparatively high temperature (75° F.), whilst *lager beer* is prepared by a very slow, prolonged fermentation at a low temperature. Differences of color in malt liquors depend chiefly upon the color of the malt. Malt is composed of germinated, dried barley grains with acrospires and radicles adherent. The U. S. P. 1880 directed that it should be fresh, of a color not darker than pale amber, and should have an agreeable odor and a sweet taste. If it lack body and taste, it has probably been already exhausted. For a description of *diastase*, the peculiar ferment which converts the starch of the grain into dextrin and dextro-glucose, see *Hordeum Decorticatum*.

Under the name of extract of malt, two distinct preparations have been put upon the market; the one being a very strong beer, the other an extract prepared from malt, and chiefly composed of dextrin and glucose, with some albumen and phosphates. The object of the process below is to obtain all of the soluble principles of malt in a permanent form. To secure this, strict attention to the details of the process is necessary. Good extract of malt should contain no starch, have the consistence of thick honey, a brown color, and should be free from empyreumatic taste. A great deal of commercial extract of malt is adulterated with glucose to a surprising extent.

Extractum Malti. U. S. 1880. *Extract of Malt. Extrait de Malt d'Orge*, Fr. *Gerstenmalz-Extrakt*, G. "Malt, in coarse powder, not finer than No. 12, *one hundred parts* [or eighty ounces av.]; Water, *a sufficient quantity*. Upon the powder, contained in a suitable vessel, pour *one hundred parts* [or five pints] of Water, and macerate for six hours. Then add *four hundred parts* [or twenty pints] of Water, heated to about 30° C. (86° F.), and digest for an hour at a temperature not exceeding 55° C. (131° F.). Strain the mixture with strong expression. Finally, by means of a water-bath, or vacuum apparatus, at a temperature not exceeding 55° C. (131° F.), evaporate the strained liquid

rapidly to the consistence of thick honey. Keep the product in well-closed vessels, in a cool place." *U. S.* 1880.

The above process does not differ materially from that of L. W. Jassoy (*Journ. de Pharm.*, 4e sér., xvi. 440), who recommends the following method. Macerate malt for three hours in its weight of cold water, then add four times its weight of water, and carefully raise the temperature to 65° C. during one hour. Filter, boil the residue with three parts of water for a quarter of an hour, remove from the fire, and allow to cool to 75° C., filter, and express the residue. Mix the liquids, maintain for some time at a temperature of 50° C., until the starch is converted into sugar. Reduce to one-third the volume by gentle boiling, allow to stand overnight, filter through a woollen strainer, and evaporate upon a water-bath to the consistence of an extract. A *dry extract of malt* has come into extensive use as an infants' food, made by artificially drying the thick syrupy extract. It is in the form of a straw-colored, coarse powder, and is given dissolved in milk or water. O. F. Romer and H. R. Randoll, of Brooklyn, have patented several improvements in the process of making extract of malt,—namely, 1, the properly ground malt is treated with an alkaline solution, in order to neutralize the fatty acids which usually impart a bad taste to the product; 2, the extract is separated from the solid matters by pressing in press-cloths, whereby it is obtained as a clear liquid with scarcely any loss. (*N. R.*, 1880, 179.) Pharmaceutically, extract of malt has been used as an emulsifying agent; it makes a good basis for a cod-liver oil emulsion, for which purpose it is admirably adapted therapeutically. The dose is from one to four drachms (3·88–15·5 Gm.).

MALVA SYLVESTRIS. L. *Common Mallow. Flores Malvæ, Folia Malvæ*, P. G. *High Mallow. Mauve Sauvage, Grande Mauve*, Fr. *Käsepappel, Waldmalve*, G. This is a perennial, herbaceous plant of the nat. ord. Malvaceæ, with a round, hairy, branching, usually erect stem, from one to three feet high, bearing alternate, petiolate, cordate, roughish leaves, which are divided into five or seven crenate lobes, and on the upper part of the stem are almost palmate. The flowers are large, purplish, and placed, from three to five together, at the axils of the leaves, upon long slender peduncles, which, as well as the petioles, are pubescent. The petals are five, inversely cordate, and three times as long as the calyx. The capsules are disposed compactly in a circular form. This species of mallow is a native of Europe, growing abundantly on waste grounds and by the way-sides, and flowering from May to August. It is sometimes cultivated in our gardens. Almost all the species of the genus are possessed of the same properties. *M. rotundifolia*, L., one of the most common, may be substituted for *M. sylvestris*. The herb and flowers have a weak, herbaceous, slimy taste, without odor. They abound in mucilage, which they readily impart to water; and the solution is precipitated by lead acetate. The infusion and tincture of the flowers are blue, and serve as a test of acids and alkalies, being reddened by the former and rendered green by the latter. The roots and seeds also are mucilaginous. Common mallow is emollient and demulcent. The infusion and decoction are sometimes employed in *catarrh, dysentery*, and *nephritic complaints*, and are applicable to all other cases which call for the use of mucilaginous liquids.

MANACA. This is a portion of the root and stem of the *Franciscea uniflora*, Pohl. (now *Brunfelsia hopeana*, Benth.), a Brazilian plant belonging to the order of Solanaceæ. It occurs in pieces from a few inches to one foot in length, and about one-half inch in diameter, very tough and woody, with a yellowish centre and a dark, very thin outer bark. The stem portion has a very small yellowish pith. H. B. Parsons (*Am. Chem. Journ.*, vol. i. No. 6) came to the conclusion that it contains no alkaloid, but R. Lenardson (*Inaug. Diss.*, Dorpat, 1884) asserts that he has found in it an alkaloid, *manacine*, besides a peculiar fluorescent substance supposed to be identical with *gelseminic acid*. Manacine is described as a light yellow, very hygroscopic powder, of a faint bitter taste, possessing very feeble basic properties, melting at 115° F., freely soluble in water and ethylic and methylic alcohol, but insoluble in ether, benzol, amylic alcohol, and chloroform. E. P. Bruer (*Therap. Gaz.*, 1882), as the result of experiments made upon the lower animals, arrived at the conclusion that manaca acts upon the spinal cord, first stimulating, and then abolishing the activity of the motor centres, the action being shared in by the respiratory centres. All the glands, especially the kidneys, were stimulated by it. In large doses he found it to produce in man lassitude, perspiration, and loose, greenish alvine discharges. Manaca has been very strongly recommended in the treatment of chronic subacute *rheumatism* and *syphilis*. The dose of the fluid extract is from ten to thirty drops three times a day. (See *Therap. Gaz.*, 1880; also New Series, vols. ii. and iii.)

MANDRAGORA OFFICINARUM. L. *Atropa Mandragora.* Linn. *Mandrake. Mandragora. Mandragore*, Fr. *Alraunwurzel*, G. A perennial European plant, with spindle-shaped root, which is often forked beneath, and is therefore compared, in shape, to the human figure. In former times this root was supposed to possess magical virtues, and was used as an amulet to promote fecundity, etc., and the superstition is still cherished by the vulgar in some parts of Europe. The plant is a poisonous narcotic, somewhat similar in its properties to belladonna, to which it is botanically allied. Crouzel isolated an alkaloid, *mandragorine*, which he found similar in properties to atropine. (*P. J. Tr.*, 1885, 1067.) It has since been more thoroughly studied by F. B. Ahrens. (*Ber.*, 1889, 2159–2161.) *Mandragorine* is colorless, inodorous, deliquescent, melts at from 77°–79° C., and has the formula $C_{17}H_{23}NO_3$. It seems to be isomeric with atropine, but is not converted into it by alkalies. The sulphate and the hydrochloride are crystalline and deliquescent. A second alkaloid in much smaller amount was also extracted, of which the gold and platinum double chlorides were formed. Both alkaloids had a mydriatic action. It was much used by the ancients as a narcotic, and as an anæsthetic agent before surgical operations. (*Journ. de Pharm.*, xv. 290) *Morion* or *Death-wine*, said to have been administered previous to the torture, was made from it. Its physiological action has been partially investigated by B. W. Richardson. (*Brit. and For. Med.-Chir. Rev.*, 1874, 242.) It is unknown as a remedy in the United States.

MANGANESE. *Manganum.* This metal and its compounds with oxygen have been already described. (See *Mangani Oxidum Nigrum.*) Several of its combinations have been proposed as medicines, to be used as tonic and anti-anæmic remedies. Manganese as well as iron is always present, in minute proportion, in healthy blood, and has been detected in various solids and fluids of the body. According to an analysis by Burin-Dubuisson, the amount of manganese in the blood-corpuscles is about one-twentieth that of the iron. It is stated, as an advantage of the preparations of manganese, that they may be prescribed in conjunction with tannic acid and the various astringent medicines, which are all incompatible with the preparations of iron. Of the manganous oxides, the *monoxide* only is strongly salifiable; and this is the oxide present in the ordinary salts of the metal. It may be obtained by precipitation, as a white hydrate, from any of the soluble manganous salts by the addition of a caustic alkali. This, according to Hannon, is a good medical preparation; but a strong objection to it is that it rapidly absorbs oxygen, and passes to the state of the brown hydrated sesquioxide.

MANGANI IODIDUM. *Manganous Iodide.* MnI_2. This very deliquescent salt may be prepared by adding manganous carbonate to aqueous hydriodic acid, filtering the solution, and granulating, carefully regulating the heat. This iodide may be administered in syrup or pill. Procter proposed the following formula for the *syrup.* Dissolve sixteen drachms of manganous sulphate, and nineteen drachms of potassium iodide, separately, in three fluidounces of water, each portion of water being previously sweetened with two drachms of syrup. Mix the solutions in a glass-stoppered bottle, and when the crystals of potassium sulphate have ceased to precipitate, throw the liquor on a strainer of fine muslin, and allow it to filter into a pint bottle, containing twelve ounces of powdered sugar. When the solution has ceased to pass, wash the filter with a little sweetened water, and add sufficient of that liquid to make the whole measure a pint. Lastly, agitate the liquid until the sugar is dissolved. Procter stated that this syrup contained about a drachm of manganous iodide in each fluidounce, and corresponded in strength to the official solution of ferrous iodide. The small proportion of potassium sulphate which remains dissolved in the syrup does not interfere with its medicinal efficacy. The dose is from ten to thirty drops, repeated several times a day. (*A. J. P.*, Oct. 1850.) Hannon makes a *pill of manganous iodide* by double decomposition between equal weights of potassium iodide and crystallized manganous sulphate. The salts are perfectly dried, accurately mixed in powder, and then rubbed up with honey, so as to reduce the whole to a pilular mass, which may be divided into four-grain pills. Assuming that the honey added compensates for the loss of water in drying, each pill will consist of about two grains of manganous iodide, one of potassium sulphate, and one of honey, and manganous sulphate in excess. The dose is one pill daily, gradually increased to six. According to Hannon, manganous iodide is particularly useful in the *anæmia* attendant on scrofula, phthisis, and cancer, and in syphilitic cachexy. It is also affirmed that when given with cinchona it removes the enlargement of the spleen of malarial fevers.

MANGANI CARBONAS. *Manganous Carbonate.* $MnCO_3$. This salt may be obtained by the following formula, which is that of Hannon. Dissolve seventeen ounces of crystallized manganous sulphate, and nineteen ounces of sodium carbonate, separately, in two pints of water, a fluidounce of syrup having been previously added to each pint; and, having mixed the solutions in a well-stoppered bottle, allow the precipitate to subside. Decant the supernatant liquid, wash the precipitate with sweetened water, allow it to drain from a cloth saturated with syrup, express, mix with ten ounces of honey, and evaporate rapidly to form a pilular mass, which is to be divided into four-grain pills. By a double decomposition between the manganous sulphate and sodium carbonate, manganous carbonate is precipitated, and sodium sulphate remains in solution. The sulphate is washed away, and the carbonate is brought to a pilular consistence with honey, which, together with the syrup, prevents the manganous oxide in the pill from rising to a higher stage of oxidation. The dose is from two to ten pills daily. Manganous carbonate was tried by Hannon as a medicine on himself. After its use for fifteen days he found his appetite improved and his pulse increased in force, and he experienced a feeling of sanguineous plethora. He afterwards exhibited the remedy in several anæmic cases, with the effect of exciting the functions to a more healthy action, increasing the strength, and improving the blood.

Manganous phosphate, *tartrate*, and *malate* have also been proposed by Hannon as useful remedies. The phosphate is prepared by double decomposition between manganous sulphate and sodium phosphate. A *syrup of manganous phosphate* has been made by T. S. Wiegand, of Philadelphia. (See his formula in *A. J. P.* for July, 1854.) Simpson, of Edinburgh, informed Geo. B. Wood that a syrup made with two grains of ferrous phosphate and one grain of manganous phosphate, in a fluidrachm of syrup, was much and advantageously used by himself and others in Edinburgh. This may be easily prepared by adding to the two ingredients mentioned five grains of glacial phosphoric acid for each grain of the ferrous phosphate. (*P. J. Tr.*, 1859, 288.) *Manganous lactate* has been given, associated with ferrous lactate, in chlorosis, in the dose of a grain, increased to five grains.

Ferro-manganic Preparations. Hannon conceives that manganese is peculiarly suited to the treatment of anæmic cases in which iron has failed, or acts very slowly; but, instead of passing at once from the use of iron to that of manganese, he prefers to give intermediately a mixture of the two metals. For this purpose he recommends the following formula. Take of crystallized ferrous sulphate six drachms and a half; crystallized manganous sulphate two drachms; sodium carbonate nine drachms; honey five drachms. Rub together, and with syrup make a mass, to be divided into four-grain pills. In this pill both the metals are present as carbonates; and, as the sodium sulphate is not washed away, it contains that salt also. The dose is from two to ten pills daily. (See the paper of Hannon, *Journ. de Pharm.*, 3e sér., xvi. 41 and 189.) The *syrup of ferrous and manganous iodides* may be prepared by the following formula. Take of potassium iodide 1000 grains; ferrous sulphate 630; manganous sulphate 210; iron filings 100; sugar, in coarse powder, 4800. Powder the iodide and sulphates separately, and, having mixed them with

the filings, add half a fluidounce of distilled water, and triturate to a uniform paste. Then add another half fluidounce of distilled water to the paste, and triturate again; and, after an interval of fifteen minutes, add a third half fluidounce, and mix. Next transfer the magma of salts to the moistened filter, supported on a funnel, and allow it to drain into a bottle holding a little more than twelve fluidounces, and containing the sugar. After it has drained, add cold boiled water by small portions at a time, until the solution of the iodides has been displaced and washed from the crystalline magma of potassium sulphate. Finally, add sufficient cold boiled water to make the whole measure twelve fluidounces. The object of the iron is to prevent the liberation of iodine. This syrup has a very pale straw color. It contains a little potassium sulphate, which does not injure it as a therapeutic agent. If the salts have not been all decomposed during their reaction, it will be greenish. Each fluidounce contains fifty grains of the mixed iodides, in the proportion of three parts of ferrous iodide to one of manganous iodide. The dose is from ten drops to half a fluidrachm. (Procter, *A. J. P.*, 1853, 198.) J. U. Lloyd proposed a process (*A. J. P.*, 1874, 6) whereby a less amount of potassium sulphate remained in the finished preparation. Manganous sulphate 240 grs.; potassium iodide 288 grs.; iodine 744 grs.; iron wire (small) 240 grs.; sugar 17 oz. av.; distilled water q. s. Place the iodine, three ounces of distilled water, and the iron wire in a glass flask, and agitate until the solution has acquired a clear greenish color, without a tinge of yellow. Filter the solution into the sugar contained in a porcelain dish; wash the filter by pouring into it two ounces of distilled water, allowing the liquid to filter into the sugar. Dissolve the manganous sulphate and potassium iodide separately in half an ounce of cold distilled water by trituration in a mortar; mix the two solutions together, and allow the potassium sulphate to separate; transfer the mixture to a wetted filter, and allow the solution of manganous iodide to filter into the sugar; when well drained, wash the precipitate in the funnel with half an ounce of *ice-cold* distilled water, and finish by agitating the mixture until the sugar is dissolved; add enough distilled water to make the whole measure twenty fluidounces; filter. Syrup of iron and manganous iodide is considered by Pétrequin to be particularly suited to the treatment of *anæmia* resulting from obstinate intermittent fevers, prolonged suppuration, and scrofulous, syphilitic, and cancerous affections.

T. S. Speer, of Cheltenham, prefers a saccharine carbonate of the two metals, made by the following formula. Dissolve three ounces and one drachm of ferrous sulphate, one ounce and one scruple of manganous sulphate, and five ounces of sodium carbonate, each, in thirty Imperial fluidounces of water, and thoroughly mix the solutions. Collect the precipitated carbonates on a cloth filter, and wash them immediately with cold water, to separate the sodium sulphate. Then press out as much water as possible, and, without delay, triturate the pulp with two and a half ounces of finely powdered sugar. Lastly, dry the mixture at a temperature not exceeding 48·8° C. (120° F.). The *saccharine iron and manganous carbonate*, as thus prepared, is a reddish-brown color, devoid of all taste, except that imparted by the sugar. The dose is five grains (0·3 Gm.), gradually increased to a scruple (1·3 Gm.), three times a day, given with the meals, or immediately after them. (See *A. J. P.*, 1854, 127.)

MANGOSTEEN. The pericarp of the fruit of the *Garcinia Mangostana*, L. (nat. ord. Guttiferæ), is said to be an active astringent, and used as such locally in various catarrhs, and also in *diarrhœa* and in *leucorrhœa*. Dose of fluid extract from half to one fluidrachm (1·8–3·69 C.c.).

MANZANILLO. According to A. Betancourt, the milky juice of this euphorbiaceous tree, growing in the West Indies, is a violent irritant, acting as a vesicant when applied to the skin, and when taken internally in doses of twenty drops causing a fatal gastro-enteritis. In doses of two drops it acts as a powerful and very certain cathartic; it is also diuretic. In Cuba it has much repute in *tetanus*. (*London Med. Rec.*, Feb. 1889.)

MARANTA. *Salep des Indes occidentales*, Fr. *Maranta Stärke*, G. Under this name the U. S. Pharmacopœia, 1870, recognized the fecula obtained from the root of *M. arundinacea*, L. (*Arrow-root*, F. *Amerikanisches Stärkmehl*, *Arrowmehl*, G.) The root (rhizome) of this plant is perennial, tuberous, fleshy, horizontal, nearly cylindrical, scaly, from six inches to a foot or more in length, and furnished with numerous long white fibres. It sends forth several tuberous, jointed, curved, white, scaly stoles, the points of which sometimes rise above the ground and become new plants. The stems, of which several proceed from the same root, are annual, slender, branched, jointed, leafy, and about three feet in height. The leaves are ovate-lanceolate, about four inches long, alternate, and supported solitarily, at the joints of the stem, upon long, sheathing footstalks. The flowers are in a long, loose, spreading, terminal panicle, at each ramification of which is a solitary linear bract. The calyx consists of three small lanceolate sepals. The corolla is white and monopetalous, with a tube longer than the calyx, and a double border, of which the three outermost segments are smallest and the two inner obovate and slightly emarginate.

The arrow-root plant is a native of the West Indies, where it is largely cultivated. It is cultivated also in the East Indies, Ceylon, Sierra Leone, the south of Africa, and was formerly in our Southern States, especially Georgia and Florida. The plant is easily propagated by cuttings of the root. An analysis by Macdonald (*Journ. Soc. Chem. Indus.*, 1887, 336) gives the following as the composition of the St. Vincent root: starch, 27·07 per cent.; fibre, 2·82; fat, 0·26; albumen, 1·56; sugar, gum, etc., 4·10; ash, 1·23; water, 62·96; total, 100·00. An analysis of the arrow-root starch from the same locality by Macdonald gave: starch, 83·70 per cent.; fibre, 0·04; fat, 0·07; sugar, gum, etc., 0·18; ash and sand, 0·14; water, 15·87; total, 100·00. The fecula is prepared in the following manner. The roots are dug up when a year old, washed, and then beaten into a pulp, which is thrown into water, and agitated so as to separate the amylaceous from the fibrous portion. The fibres are removed by the hand, and the starch remains suspended in the water, to which it gives a milky color. The milky fluid is strained through coarse linen, and allowed to stand that the fecula may subside, which is then washed with a fresh portion of water, and afterwards dried in the sun. We obtain the true arrow-root chiefly through London

from the West Indies. That from the Bermudas has in general been most highly esteemed. The term Bermuda arrow-root is now applied commercially to any carefully prepared arrow-root, without reference to the place of its production. Jamaica arrow-root is an inferior article, which is to some extent imported directly. St. Vincent, one of the British West India Islands, furnishes a large amount of the arrow-root imported into this country.

Other plants contribute to furnish the arrow-root of commerce. Lindley states that it is procured in the West Indies from *Maranta allouia*, Aubl. (now *Calathea allouia*, Lindl.), of the nat. ord. Scitamineæ, and possibly other species, besides *M. arundinacea*, L. Under the name of *M. indica*, Tussac describes a distinct species, which he says was originally brought from the East Indies, and is now cultivated in Jamaica. This, however, is generally considered as a mere variety of *M. arundinacea*, from which it differs chiefly in having leaves more elongated at the point, and smooth on both sides. Very fine arrow-root is obtained in the East Indies from the root of *Curcuma angustifolia* of Roxburgh, which is cultivated in Travancore. But the product is lighter than the Maranta arrow-root, and does not so quickly make a jelly. Cassava arrow-root is prepared in Brazil from the *Janipha Manihot*, and sometimes sold as arrow-root or used to adulterate the true arrow-root. A variety of arrow-root has been imported from the Sandwich Islands. Mr. Nuttall, during a visit to these islands, found that it was obtained from a species of tacca, which he described by the name of *Tacca oceanica*. (*A. J. P.*, ix. 305.) It is said that a similar product is afforded by *Tacca pinnatifida*, Forst., growing in the East India province of Arracan. (*P. J. Tr.*, vi. 383.) Arrow-root has been brought from Florida, prepared near St. Augustine from the root of *Zamia integrifolia*, by a process similar to that employed for the fecula of the Maranta (Dr. J. Carson, *A. J. P.*, xiv. 22); but care must be taken not to confound this with the genuine maranta from the same State. The tuberous roots of different species of Alstrœmeria, growing in South America, yield a fecula used for the same purposes as the maranta; and a specimen, under the name of *Talcahuana arrow-root*, was sent from Chili by Dr. Ruschenberger to Prof. Carson, of this city, who ascertained it to be the product of the *Alstrœmeria Ligtu*, L. (nat. ord. Amaryllidaceæ). (*Ibid.* xxxii. 289.) In the West Indies, substitutes for arrow-root are furnished by the roots of *Dioscorea sativa*, L. (now *D. spinosa*, Roxb.), of the nat. ord. Dioscoreaceæ, or *yam*, and of *Colocasia esculenta*, Schott. (now *C. antiquorum*, Schott.), of the nat. ord. Aroideæ, and by the fruit of *Artocarpas incisa*, L. (nat. ord. Urticaceæ), or bread-fruit tree. Attempts have been made to substitute finely prepared potato starch for arrow-root, and there is no doubt that in nutritive properties it is quite equal, but patients complain of an unpleasant taste of the potato which it is apt to retain.

Arrow-root is in the form of a light white powder, or of small pulverulent masses, without smell or taste. It has a firm feel when pressed between the fingers, and produces a faint crackling sound when rubbed. It is a pure starch, corresponding in chemical properties with that of wheat and the potato. It is very apt to be musty, and should then be rejected. The odor and taste are the best criteria of its purity. It should be perfectly free from smell and unpleasant flavor. Prof. Procter rendered musty arrow-root sweet and fit for use by washing it thoroughly with two successive portions of cold water, and then drying it upon frames of muslin in a warm place. (*A. J. P.*, xiii. 188.) Arrow-root is sometimes adulterated with wheat or potato starch. These may be detected by the microscope. Hydrochloric acid has been proposed as a test. A mixture of equal parts of that acid and of water, rubbed with about half its weight of potato or wheat starch, very quickly forms so thick a mucilage that the mortar in which the trituration is effected may be raised by the pestle; while the same result does not take place with rice flour or arrow-root under twenty-five or thirty minutes. So small a proportion as from 4 to 6 per cent. of the impurity may, it is asserted, be detected in this way. (*Journ. de Pharm.*, 3e sér., ii. 246.) The German Pharmacopœia test is as follows: "When arrow-root is shaken for ten minutes with ten parts of a mixture consisting of two parts of hydrochloric acid and one part of water, the greater part should separate unchanged, and it should not become mucilaginous nor yield an herbaceous odor similar to that of green unripe bean-pods."

As the microscope offers the best means of distinguishing the different varieties of fecula sold as arrow-root, or used for its adulteration, it is proper to indicate the form of their granules as exhibited by this instrument. Those of *Maranta arrow-root* are rarely oblong, somewhat ovate-oblong, or irregularly convex, with very fine rings, a circular hilum which cracks in a linear or stellate manner, and small mammillary processes occasionally projecting from them. (Pereira.) The largest are the 750th of an inch, but many are not more than the 2000th of an inch long; and their breadth is generally two-thirds of their length. (Christison.) The granules of the *East India arrow-root* are, according to Pereira, of unequal size, ovate or oblong-ovate, flattened, and often furnished with a very short neck or nipple-like projection. The rings are numerous, close, and very fine; and the hilum, which is situated at the narrow extremity, is circular, small, and indistinct. The microscopic appearance of the *tapioca fecula* will be described under the head of *Tapioca*. The *Tacca fecula* from the South Sea Islands, examined by Pereira, consisted of circular, muller-shaped, or polyhedral granules, with few and not very distinct rings, and a small, circular hilum, which cracked in a linear or stellate manner. The *Florida* or *Zamia arrow-root* was found by Dr. Carson to consist of granules forming the half, third, or quarter of a solid sphere. The *potato starch* granules are of various shape and size, but generally ovate or elliptical, and from the 7000th to the 300th of an inch in length; the largest being inferior in size only to the largest of the canna starch or *tous-les-mois*. (See *Canna*.) They are strongly marked with concentric rings, and have a circular hilum, from which usually proceed the cracks observable in some of the larger grains.

Medical Properties and Uses. Arrow-root affords a light, very mild, and easily digested article of diet, well adapted for the sick and convalescent, and peculiarly suited, from its demulcent properties, to bowel complaints. It is prepared by dissolving it in hot water or hot milk, with either of which it forms a pearly gelatinous solution,

and, if in sufficient quantity, a jelly-like mass on cooling. A tablespoonful will communicate sufficient consistence to a pint of water. It should first be formed into a perfectly smooth paste with a little cold water or milk, and the boiling water then gradually added with brisk agitation. The preparation may be rendered more palatable by lemon-juice and sugar, or by wine and spices.

MASSOI BARK. In Eastern commerce certain aromatic barks occur, under the name of massoi barks. Of these, three are believed by F. Hekmeyer to be the products respectively of *Cinnamomum xanthoneurum*, Blume, *Cinnamomum kiamis*, Nees (now *C. burmanni*, Blume), and *Sassafras goesianum*, Teijsm. and Binn. (now *Massoia aromatica*, Becc.), all of the nat. ord. Laurineæ. For a description of these barks, by E. M. Holmes, see *P. J. Tr.*, 1888, 465. The massoi bark which comes from New Guinea, and from which Messrs. Schimmel have distilled an oil resembling that of nutmeg and cloves, probably has a different origin from the true massoi bark.

MATA. This name is given, in New Mexico, to an herb much used in that region as an addition to tobacco in smoking. It is said, when burning, to have an odor like that of the tonka bean, and, when smoked with tobacco, to correct the extremely disagreeable smell imparted by this to the clothing and apartments. From imperfect specimens of the plant raised by E. S. Wayne and sent to Maisch, it is supposed to be a Eupatorium, probably the *E. incarnatum* of Walter, which is indigenous in Texas. (*A. J. P.*, 1868, 122.)

MEAT, RAW. *Raw meat* has been recommended as an article of diet for consumptive patients, and especially for scrofulous children and in other cachectic cases, and is asserted to have proved highly useful. It may also be employed with great advantage in *dyspepsia* and *chronic diarrhœa*, especially in children. It was brought into notice by Fuster, of Montpellier, France. The following formula is recommended by Reveil. Take of fillet of beef 100 grammes, deprive it carefully of all fatty and membranous matter, cut it up finely, beat it in a mortar, and add of powdered sugar 20 grammes, sodium chloride 1·5 grammes, potassium chloride half a gramme, and powdered black pepper one-fifth of a gramme. The mixture is to be taken in teaspoonful doses through the day. (*Ann. de Thérap.*, 1866, 145.) An excellent method of exhibiting raw meat is to *scrape* a thin steak and mix the pulp thus obtained with brandy. Ivon asserts that a very pleasant emulsion is afforded by the following formula (*A. J. P.*, 1874, 346). Take of raw meat 250 parts, of sweet almonds 75 parts, of bitter almonds 5 parts, of white sugar 80 parts Blanch the almonds and beat the whole into a paste. In dissolving, milk may be used instead of water.

Pemmican, which before the extermination of buffaloes was much used in the northwestern part of the United States as an excellent condensed food, was made by mixing equal parts of buffalo meat and buffalo tallow, and pouring the melted mixture into sacks of untanned buffalo hide. For processes for *meat biscuit* and *flour of meat*, see *U. S. D.*, 17th ed., p. 1685; see also *Extractum Carnis*, 18th ed., p. 1654.

MEDEOLA VIRGINIANA. L. *Gyromia Virginica.* Nuttall. *Indian Cucumber.* An indigenous perennial herb of the nat. ord. Convallariaceæ, growing in all parts of the United States. The root, which in shape and flavor bears a strong resemblance to a small cucumber, is said by Pursh to be eaten by the Indians, and by Barton to be useful as a diuretic in *dropsies*.

MEGARRHIZA CALIFORNICA. Torr. (Now *Echinocystis fabacea*, Nand.) *Man-root.* (Nat. ord. Cucurbitaceæ.) Mr. J. P. Heaney has obtained a substance from this root of resinous character which he calls *megarrhizitin*, and another which he believes to be a glucoside and calls *megarrhizin*. It is said to be actively cathartic. (*A. J. P.*, 1876, 451.) A second glucoside was obtained by W. M. Young (*A. J. P.*, 1883, 195), to which the name of *megarrhin* was given. It resembles saponin, and possesses the property of dilating the pupil. Young also found two resins, one soluble in alcohol and the other soluble in ether.

MELASTOMA ACKERMANNI. This Colombian plant of the nat. ord. Melastomaceæ is used in South America as an anti-neuralgic. Its abundant essential oil resembles methyl salicylate, if indeed it be not identical with it. (See *New Rem.*, Aug. and Sept., 1883.)

MELILOTUS OFFICINALIS. (L.) Lam. *Melilot. Herba Meliloti*, P.G. *Sweet Clover. Summitates méliloti. Mélilot*, Fr. *Steinklee, Melilotenklee*, G. An annual or biennial plant of the nat. ord. Leguminosæ, indigenous in Europe, and growing also in this country. We have two varieties, one with yellow, the other with white flowers, which are considered by some as distinct species. The plant, when in flower, has a peculiar sweet odor, which, by drying, becomes stronger and more agreeable, somewhat like that of the tonka bean. This similarity is accounted for by the fact that *coumarin*, $C_9H_6O_2$, the chief constituent of tonka beans, is present in melilot, combined with *melilotic acid*, $C_9H_{10}O_3$, and *coumaric acid*, $C_9H_8O_3$, of which latter acid *coumarin* is the anhydride. Melilot is practically inert.

MENTHA PULEGIUM. L. *European Pennyroyal.* This European labiate yields an oil which is known in England as the *oil of pennyroyal*, and must not be confounded with the American plant of the same name. The oil, which is also known as the *oil of Poley*, has been examined by Beckmann and Pleissner (*Ann. der Chem. und Pharm.*, 262, 1), who discovered as the most important constituent *pulegone*, $C_{10}H_{16}O$, an unsaturated ketone. It boils under a pressure of 60 Mm. at from 130°–131° F., turns the plane of polarization to the right, and has a sp. gr. 0·9323 at 0° C. It forms crystalline compounds with hydroxylamine and with hydrogen bromide. When reduced by sodium in ethereal solution pulegone is changed into menthol. Pulegone is most abundant in the Spanish oil, and less abundant in American and Algerian oils. (See also Wallach, *Ann. Chem. und Pharm.*, 272, 122, and Semmler, *Ber. Chem. Ges.*, 25, 3515.) It is stated (*Brit. Med. Journ.*, March, 1890) that the oil is largely used for the purpose of producing abortion, and is popularly believed to be safer and more certain than the other volatile oils. The possession by it of such power is, however, denied by Taylor, the famous toxicologist.

MENTHIODOL. This substance has been recommended as a local application in neuralgia. It is prepared by carefully heating four parts of menthol in a capsule, adding one part of finely powdered iodol, and triturating into a homogeneous

mass, which is made into cones or pencils of a suitable size. If the mass be too hard, it can be softened by remelting with a minute quantity of camphor.

MENYANTHES TRIFOLIATA. L. *Buckbean. Marsh Trefoil.* Willd. *Bogbean. Water Shamrock. Folia Trifolii Fibrini*, P. G. *Menyanthe, Trèfle d'eau (de marais)*, Fr. *Fieberklee, Bitterklee, Dreiblatt*, G. This gentianaceous plant has a perennial, long, round, jointed, horizontal, branching, dark-colored root or rhizome, about as thick as the finger, and sending out numerous fibres from its under surface. The leaves are ternate, and upon long stalks, which proceed from the end of the root, and are furnished at their base with sheathing stipules. The leaflets are obovate, obtuse, entire or bluntly denticulate, very smooth, beautifully green on their upper surface, and paler beneath. The flower-stalk is erect, round, smooth, from six to twelve inches high, longer than the leaves, and terminated by a conical raceme of whitish, somewhat rose-colored flowers. The calyx is five-parted; the corolla funnel-shaped, with a short tube, and a five-cleft, revolute border, covered on the upper side with numerous long, fleshy fibres. The anthers are red and sagittate; the ovary oval, supporting a slender style longer than the stamens, and terminating in a bifid stigma. The fruit is an oval, two-valved, one-celled capsule, containing numerous seeds. This beautiful plant is a native both of Europe and North America, growing in boggy and marshy places always moist and occasionally overflowed with water. It grows in bogs from Greenland to Alaska and south to Pennsylvania, Minnesota, and California. The flowers appear from May to July. All parts of it are efficacious, but the leaves only were official.

The taste of buckbean is intensely bitter and somewhat nauseous, the odor of the leaves faint and disagreeable. The plant has been examined by Trommsdorff, Brandes, Landerer, and Kromayer. Its virtues depend on a bitter principle denominated *menyanthin*, which may be obtained sufficiently pure for use by treating the spirituous extract of the plant with hydrated lead oxide, removing the lead by hydrosulphuric acid, filtering and evaporating the liquor, exhausting the residue with alcohol, and again evaporating with a gentle heat. It has a pure bitter taste, is soluble in alcohol and water, but not in pure ether, and is chemically neutral. Kromayer (1865) assigns to it the formula $C_{30}H_{46}O_{14}$, and states that it breaks up on heating with dilute sulphuric acid into a fermentable sugar and *menyanthol*, C_8H_8O, a colorless, difficultly volatilizable oil, smelling like bitter almond. K. Leuderich (*Arch. der Pharm.*, 1892, 88 and 48) has since studied *menyanthin*, and gives it the formula $C_{33}H_{50}O_{14}$, and states that its decomposition products are a phenol-like body, *menyanthol*, $C_7H_{11}O_2$, a resinous product, and a left-rotatory sugar. With the ordinary properties of the bitter tonics, menyanthes unites a cathartic power, and in large doses it is apt to vomit. It was formerly held in high esteem in Europe as a remedy in numerous complaints, among which were *intermittents*, *rheumatism*, *scrofula*, *scurvy*, *dropsy*, and *jaundice*. The dose of the powdered leaves or root as a tonic is from twenty to thirty grains (1·3–1·9 Gm.); of an infusion, prepared with half an ounce to a pint of boiling water, from one to two fluidounces; and of the extract, ten or fifteen grains, to be repeated three or four times a day. A drachm of the powder, or a gill of the strong decoction, generally purges, and often occasions vomiting.

MERCURETHYL CHLORIDE. $Hg(C_2H_5)Cl$. This has been proposed as a substitute for corrosive sublimate, but is not at all likely to come into use. (See *A. J. P.*, xlv. 337.)

MERCURIALIS ANNUA. L. An herbaceous European plant, of the family of Euphorbiaceæ, which has been employed from the most ancient times as a purgative, diuretic, and emmenagogue. When boiled, it loses its acridity, and in this condition has been used as an emollient. Another species, *M. perennis*, L., also a native of Europe, is poisonous. (Mérat and De Lens.) Reichardt has discovered in *M. annua* a volatile alkaloid, which he named *mercurialine*. According to E. Schmidt (*P. J. Tr.*, vol. x. 29), *mercurialine* is identical with *methylamine*, $CH_3.NH_2$, and is associated in the mercurialis with *trimethylamine*. It is a liquid of an oily appearance, narcotic odor, and alkaline reaction; boils at 140° C. (284° F.); forms salts with the acids; absorbs carbonic acid; has a strong affinity for water; on exposure to the air it is changed into a resin of a buttery consistence, and is said to be poisonous to man; but Hugo Schulz (*Archiv f. Exper. Path. und Pharm.*, April, 1886, 88) found that neither the fluid extract nor the herb given as food was capable of killing either the pig or the rabbit, and that four and a half grains (0·29 Gm.) of the mercurialine hypodermically injected had no effect. The urine is increased in quantity and colored reddish.

MERCURIC SULPHIDE. *Hydrargyri Sulphidum Rubrum, U. S.* 1880. *Red Sulphide of Mercury. Cinnabar.* HgS; 231·78. HgS; 231·7. *Hydrargyri Sulphuretum Rubrum, U. S.* 1870. *Cinnabaris. Hydrargyrum Sulfuratum Rubrum*, P. G. *Sulfuretum Hydrargyricum. Sulfure rouge de Mercure*, Fr. *Rothes Schwefelquecksilber, Zinnober*, G. This preparation, which was formerly official both in the United States and British Pharmacopœias, has been finally dropped from each. It can be made by mixing together forty parts of mercury and eight parts of sulphur, and subliming the mass after it has become cold. In order to render the combination more prompt, the sulphur is first melted; and the addition of the mercury should be made gradually, while the mixture is constantly stirred. Dr. Barker recommends the addition of the metal by straining it upon the melted sulphur through a linen cloth, whereby it falls in a minutely divided state. When the temperature has arrived at a certain point, the combination takes place suddenly with a slight explosion, attended by the burning of the sulphur, which must be extinguished by covering the vessel. A black mass will thus be formed, containing generally an excess of sulphur, which, before the sublimation is performed, should be got rid of by gently heating the matter, reduced to powder, on a sand-bath. The sublimation is best performed, on a small scale, in a closely stopped glass matrass, which should be placed in a crucible containing sand, and, thus arranged, exposed to a red heat. The equivalent quantities for forming this sulphide are 32 of sulphur and 199·7 of mercury.

Cinnabar is seldom prepared on a small scale, being made in large quantities for the purposes of

the arts. Until within a few years it was nearly all manufactured in Europe, but it is now made to an enormous extent in this country. In Holland, where it is largely manufactured, the sulphur is melted in a cast-iron vessel, and the mercury is added in a divided state, by causing it to pass through chamois leather. As soon as the combination has taken place, the iron vessel is surmounted by another, into which the cinnabar is sublimed. The larger the quantity of the materials employed in one operation the finer will be the tint of the product. It is also important in the manufacture to use the materials pure, and to drive off any uncombined sulphur which may exist in the mass before submitting it to sublimation. In the United States, Martin's method, consisting of the agitation together of quicksilver, sulphur, and an alkaline sulphide, appears to have the preference. Another process for its manufacture in the wet way very largely employed is Brunner's. (*Wagner's Chem. Tech.*, 13th ed., 1889, 552.)

Properties, etc. "Brilliant, dark red, crystalline masses, or a fine, bright, scarlet powder, permanent in the air, odorless and tasteless, insoluble in water, alcohol, nitric or hydrochloric acid, or in dilute solutions of alkalies. It is dissolved by nitrohydrochloric acid with separation of sulphur. When heated, the salt becomes brown and then black, but, on cooling, it reassumes its red color. At a higher temperature it takes fire, burns with a bluish flame, emitting the odor of burning sulphur, and is finally volatilized without residue. On dissolving the salt in nitrohydrochloric acid and adding an excess of stannous chloride, metallic mercury is precipitated. If the salt be treated with warm solution of potassa, the filtrate, after being acidulated with hydrochloric acid, should not yield a yellow or orange-colored precipitate (arsenic, antimony), nor should it produce a colored precipitate with acetate of lead (chromates, iodides, or other sulphides). If the salt be digested with diluted nitric acid for five minutes, the filtrate, after being much diluted, should not be darkened by hydrosulphuric acid (abs. of red oxide of mercury or of lead)." *U. S.* 1880. In close vessels at a red heat it sublimes without decomposition, and condenses in a mass, composed of a multitude of small needles. When duly levigated, it furnishes a brilliant red powder, which is the paint called *vermilion*. The same compound occurs native, being the sole ore from which mercury is extracted. The preparation, if purchased in powder, should be carefully examined, as, in that state, it is sometimes adulterated with red lead, dragon's blood, or chalk. If red lead be present, acetic acid, digested with it, will then yield a yellow precipitate (lead iodide) with potassium iodide. Dragon's blood may be detected by alcohol, which will take up the coloring matter of that substance, if present; and, if chalk be mixed with it, effervescence will be excited on the addition of an acid. This sulphide consists of one atom of mercury 199·8, and one of sulphur 31·98 = 231·78.

Cinnabar is at present only employed in medicine by fumigation, as a rapid sialagogue, in syphilitic affections, when it is desired to obtain an immediate mercurial impression. Half a drachm may be thrown on a red-hot iron, in a close apartment, and fumes inhaled as they arise. These consist of sulphurous acid gas and mercurial vapor, the former of which must prove highly irritating to the patient's lungs. A better substance for mercurial fumigation is black mercurous oxide.

MERCURY. A number of compounds of mercury have been prepared since the sixteenth edition of the United States Dispensatory, for medicinal uses, especially for hypodermic injections. The most important of these are as follows.

Hydrargyrum Amidopropionicum. Alanin Mercury. Lucca asserts that this compound may be administered internally or subcutaneously, in doses of 0·10 Gm., with great advantage over other antisyphilitics. To prepare "alanin mercury," crystallized amidopropionic acid is dissolved in water, heated to boiling, and mercury added as long as it is dissolved. The filtrate is rapidly evaporated, and the compound then separates in white crystalline needles.

Hydrargyrum-Asparagin. $(C_4H_7N_2O_3)_2Hg$. *Asparagin Mercury.* This preparation is made by adding mercury in excess to the hot aqueous solution of asparagin, filtering while cold, and determining by trituration the proportion of mercury, the intention being that the solution shall contain a half per cent. of asparagin mercury. It is a colorless, inodorous preparation, which has been employed for hypodermic injection by Neumann and others in the treatment of syphilis. It is asserted that the injection produces no local disturbance, even when repeated daily, and that the mercurial passes with extraordinary rapidity into the circulation and acts with corresponding promptness upon the morbid process, almost the whole of the mercurial being recoverable from the urine twenty-four hours after injection. The hypodermic dose of asparagin mercury is one-sixth of a grain (0·01 Gm.). (*Nouv. Remèdes*, May, 1892.)

Hydrargyri Benzoas, Mercuric Benzoate ($Hg(C_6H_5COO)_2 + H_2O$), is obtained by double decomposition between an alkaline benzoate and a mercuric salt, for the treatment of syphilitic diseases; a white crystalline, odorless, and tasteless powder, which is sparingly soluble in water, but easily in alcohol as well as in aqueous solutions of sodium chloride, the latter effect being due to its property of forming easily soluble double salts with the haloids. It has been strongly recommended by Stukowenkow for hypodermic use and in *gonorrhœa*. For urethral injections the solution may be 1 to 1000 or 2000, with an equal quantity of sodium chloride. For subcutaneous injections it is employed in conjunction with cocaine, the following being the proportions: hydrargyri benzoatis, 0·2 to 0·3; aquæ dest., 40·0; sodii chloridi, 0·1; cocainæ hydrochlor., 0·15. (*Arch. d. Pharm.*, April, 1889.)

Hydrargyri Bromidum, Mercurous Bromide (Hg_2Br_2), is formed by adding potassium bromide to mercurous nitrate. It falls as a white curdy precipitate. *Mercuric bromide* ($HgBr_2$) may be obtained by digesting mercurous bromide in water containing bromine. Mr. A. E. Ebert prepares it by reaction between potassium bromide and official solution of mercuric nitrate. For the particulars of the process, see a paper by Mr. Ebert in the *A. J. P.*, March, 1867, 107. It is in the form of colorless crystals, soluble in water and alcohol. Exposed to heat it melts and sublimes. These bromides are analogous in composition and medical properties to the corresponding mercury iodides. Mercurous bromide is given in the dose of a grain (0·065 Gm.) daily, gradually increased. Mercuric

bromide resembles corrosive sublimate, is an irritant poison, and may be administered in doses of the sixteenth of a grain (0·004 Gm.), gradually increased to the fourth (0·016 Gm.), either in the form of pill or in ethereal solution made by dissolving a grain in a fluidrachm of ether.

Hydrargyri Carbolas, Mercuric Carbolate or *Phenylate*, $(C_6H_5O)_2Hg$, occurs as colorless needles, insoluble in water and cold alcohol, but taken up by hot alcohol, by ether or a mixture of alcohol and ether, and by glacial acetic acid. This substance has been used by the mouth as an antisyphilitic, in doses of from a third to a half grain (0·02–0·032 Gm.).

Hydrargyri et Zinci Cyanidum, Mercuric and Zinc Cyanide, is stated by Dunstan to be a true chemical compound, with the formula $Zn_4Hg(CN)_{10}$. It is a white powder, entirely insoluble in water. This substance has been very highly recommended by Sir J. Lister as an antiseptic dressing, and is believed by him to be practically free from irritating or poisonous properties.

Hydrargyri Iodotannas, Iodotannate of Mercury, according to J. Nourry (*Bull. Gén. Thér.*, April, 1888), is a soluble, non-irritating compound. For hypodermic use a solution is prepared from mercury 0·008 Gm. (⅛ grain), iodine 0·03 Gm., kramerotannic acid 0·04 Gm., and glycerin 1 C.c.

Hydrargyri Oxycyanidum, Oxycyanide of Mercury, $Hg_2O(CN)_2$, has been highly lauded by M. Chibret as a germicide in diseases of the eye, having the advantage of being much better borne than the bichloride. He uses one part in fifteen hundred of water.

Hydrargyri Peptonas. Under this name pharmacists have offered a yellowish liquid, with a saline feebly metallic taste and slight acid reaction. It is alleged that it may be used hypodermically without production of pain. One C.c. is said to be equivalent to one-sixth of a grain of mercuric chloride. As a substitute for this has been proposed *gluten-peptone sublimate.* This has been introduced as a white lustrous hygroscopic powder, or more commonly in 1 per cent. solution. It is said to contain 25 per cent. of corrosive sublimate, and to be an efficient, non-irritating preparation for hypodermic use.

Hydrargyri Pyroboras. The *pyroborate of mercury*, HgB_4O_7, an amorphous brown, insoluble powder, has been commended by V. Tokayer (*Pharm. Post*, 1892) as a local application in the treatment of specific and other ulcerations.

Hydrargyri Salicylas, the *neutral salicylate of mercury*, a white, amorphous, tasteless, and odorless powder, scarcely soluble in alcohol and water, and having the formula $(C_6H_4OHCO_2)_2Hg$, was first introduced as a remedy by Dr. Silva Araujo, of Rio Janeiro, who affirmed that it had less influence upon the alimentary tract, that it was better borne than any other preparation of mercury, and that it was also more effective in *syphilis.*

The statements of Araujo have, in a measure, been confirmed by various physicians, and especially has it been asserted that the salicylate may be given by intramuscular injection without producing local effects, and with a rapid mercurialization of the system. The dose internally is from one-fourth to one grain (0·01–0·06 Gm.), two or three times a day. Hypodermically, one-sixth of a grain (0·01 Gm.) may be given with an equal amount of potassium carbonate, in distilled water.

Hydrargyrum Sozojodolicum, $(C_6H_2I_2(OH)SO_3)_2Hg$, is a lemon-yellow powder, scarcely soluble in water, but more readily in sodium chloride. This preparation, which is said to contain 31 per cent. of quicksilver and 38 per cent. of iodine, has been especially recommended by Witthauer (*München. Med. Wochensch.*, Aug. 1892) in the treatment of *syphilitic ulcerations, enlarged glands*, and skin diseases, in the form of a 1 per cent. salve. The 1 per cent. solution is also used by Prof. Genzmer as an injection into diseased joints, etc.

Hydrargyri Succinimidum. $(C_4H_4O_2N)_2Hg$. *Succinimide of Mercury.* This drug may be formed by heating together succinic acid, carbonic anhydride, and ammonia. It furnishes with mercuric oxide a compound which occurs as a white silky powder, soluble in water. This solution remains quite unchanged when kept. According to Dr. Vollert, the solution of one and three-tenths grammes of this salt in one hundred of water is free from irritant properties, and when used hypodermically produces no disagreeable local or even secondary symptoms. (*Therap. Monatssch.*, 1888.)

Hydrargyri Sulphocyanas. $Hg(CyS)_2$. *Sulphocyanate of Mercury*, formerly called sulphocyanide of mercury, is produced by mixing dilute solutions of mercurous nitrate and sulphocyanate of potassium. The white precipitate which falls, when dried, swells up suddenly when heated, giving off nitrogen, carbon disulphide, and vapor of mercury, leaving a gray residue, *mellone.* The salt is used in the preparation of the toy, *Pharaoh's serpents.*

Hydrargyri Tannas. Tannate of Mercury, which was first brought forward by Lustgarten (*N. Y. Med. Journ.*, March, 1892), has received some favor at the hands of syphilographers, and is official in the Austrian Pharmacopœia under the name of *Hydrargyrum tannicum oxydulatum.* It is declared that it has the especial advantage of being unabsorbed in the stomach, but decomposed by the alkaline juices of the duodenum, in such a way as to yield very minute globules of metallic mercury for ready absorption. It may be prepared either by precipitating concentrated solution of tannic acid and oxydulated mercurous nitrate or by rubbing together tannic acid and oxydulated mercurous nitrate. According to Lustgarten, the first process yields the better preparation. In *syphilis*, three grains (0·19 Gm.) may be given to the adult daily, increasing to five grains (0·3 Gm.) or more until one hundred or one hundred and fifty grains are taken. It is asserted that it does not irritate the alimentary canal.

Thymolnitrate of mercury, $(C_{10}H_{13}O)Hg–HgNO_3$; also *thymolacetate of mercury*, $(C_{10}H_{13}O)Hg–HgC_2H_3O_2$; also *thymosulphate of mercury*, $[(C_{10}H_{13}O)Hg–Hg]_2SO_4$, have all been used with asserted good effects in syphilis, in hypodermic doses of from one-twelfth to one-sixth of a grain (0·005–0·01 Gm.) (See *Merck's Jahresbericht*, 1891, 1892; also *Wien. Klin. Wochens.*, March, 1892.) Besides these preparations, *naphtolate of mercury*, a lemon-yellow powder, containing 30·8 per cent. of mercury; and the *mercuric formamidate*, a solution obtained by the action of formamide upon mercuric oxide, and the *tribromphenol acetate of mercury*, containing about 30 per cent. of quicksilver, have been put upon the market by E. Merck and other chemists.

MESEMBRYANTHEMUM CRYSTALLINUM. L. *Ice-plant. Diamond Fig. Glaciale. Cristalline*, Fr. *Eiskraut*, G. A biennial plant of the nat. ord. Ficoideæ, a native of the south of Europe. The stem and under surface of the leaves are covered with crystalline drops, which give the plant the appearance of being coated with ice. H. Mangon obtained as much as 43 per cent. of salts of potassium and sodium from the dried leaves. (*A. J. P.*, 1883, 370.) The herb is without smell, and has a saline somewhat nauseous taste. It is considered demulcent and diuretic, and has been commended as a remedy in various complaints, especially those of the mucous membrane of the lungs and urinary passages. It has also been used in *dropsy*. The expressed juice is the form in which it has been generally employed.

MESENNA. *Musenna. Bisenna. Muséna, Moucéna*, Fr. *Musennarinde*, G. Under these different names has been brought into notice, as a powerful *tænifuge*, the bark of an Abyssinian tree, named by Brongniart *Albizzia anthelmintica* (nat. ord. Leguminosæ). The bark is in flat pieces from five to ten inches long, smooth, slightly fissured, of a rusty-gray color exteriorly, and pale yellow and fibrous within. It consists of four layers, one of which contains very large cells, with thick coats, and is supposed to be the active part. E. Caventou and Legendre have examined the bark, and found in it no alkaloid, but a peculiar, acid, resinous substance, having an acrid taste, analogous to that of the bark, of which it is probably the active principle. The *musennin* of Thiel is probably the same, although not as yet in a pure state. The Abyssinians employ the powdered bark, in the dose of about two ounces, which they take in various ways, suspended in water or other liquid, or mixed with flour in the form of bread, or made into a confection with honey, butter, etc. It is taken in the morning, three or four hours before breakfast, and no other precautions are used. It produces no pain nor any disturbance of the functions, not even purging actively. Fragments of the worm are voided the same evening, and the greater portion of it the next day. Successful trials of the remedy have been made elsewhere than in Abyssinia, though M. Rayer has collected cases which tend to discountenance the opinion of its vermifuge powers. But the bark may in these instances have been injured by time. (See *Ann. de Thérap.*, 1862, 161.)

MESQUITE GUM. *Gum Mesquite. Gum Mezquite.* This is the product of *Prosopis juliflora*, D. C. (*Algarobia glandulosa*, Torrey and Gray), a small thorny tree or shrub belonging to the nat. ord. Leguminosæ, and growing in New Mexico, Texas, and other neighboring regions, where it covers vast extents of country. According to R. B. Marcy, the tree was first described by Edwin James, who attended Long's exploring expedition to the Rocky Mountains many years since. The tree is found between 26° and 36° of N. latitude, and extends from 97° to 103° of W. longitude, over a region containing more than 500,000 square miles. In its botanical affinities and habits it is closely analogous to the Acaciæ, which yield gum arabic. The fruit is a long, compressed pod, filled with a sweet pulp, which is said to contain 30 per cent. of grape sugar, and is used very largely by the Indians as food for themselves and horses. A gum exudes from the stem and branches. It occurs in irregular, roundish pieces, of various sizes and usually of a dark amber-brown color, though sometimes, especially when gathered from young trees, it is nearly colorless. Procter found it to resemble gum arabic in its solubilities, but to differ essentially in some of its chemical reactions, especially in not being precipitated by lead subacetate, and its strong solution not being coagulated by borax. (*A. J. P.*, xxvii. 224.) Campbell Morfit, of Baltimore, found it to approximate very closely to gum arabic in ultimate composition, its constituents being carbon, hydrogen, and oxygen, with 3 per cent. of inorganic matter. He found also a very little bassorin (0·206 per cent.), which did not exist in the specimens examined by Procter. (*Am. Journ. of Sci. and Arts*, March, 1855, 264. See also *A. J. P.*, 1885, 542, for a brief description of the gum and its character.) There can be little doubt that this gum has all the valuable medicinal properties of gum arabic, and might be substituted for it in all cases, with this considerable advantage, that it may be added to diluted solution. As much as 24,000 pounds are said to have been gathered in 1872, and chiefly used by confectioners.

The beans of a second species of Prosopis (*P. pubescens*, Benth.) are largely employed as food by the Indians. The wood of both species is exceedingly hard and very valuable.

METHACETIN. *Para-acetanisidine. Para-oxymethylacetanilid.* $C_6H_4(OCH_3).NHC_2H_3O$. This differs from acetanilid in having an atom of the nucleus replaced by the oxymethyl group (OCH_3). It forms lustrous crystals free from color, odorless, melting at 127° C., and distilling at higher temperatures unchanged. It is scarcely soluble in cold water, readily soluble in hot water, soluble in alcohol, acetone, chloroform, glycerin, and fatty oils. Methacetin appears to be a powerful antipyretic. According to F. Mahnert, when given in toxic dose to rabbits, it causes convulsions and death through its actions on the central nervous system. The same authority states that its 1 per cent. solution is distinctly antiseptic. It has been used as an antipyretic by various clinicians, with concordant results. The fall of temperature which it produces is very great, amounting in some cases of *typhoid fever* to nearly six degrees, and the after-rise is slow. Moreover, minute doses have a distinct power in prolonging the apyrexia. The fall of temperature is accompanied by a violent sweating, but no other disagreeable symptoms have been noticed, except in one or two cases, when a tendency to collapse was produced. In *phthisis* and similar diseases the tendency to profuse sweating strongly interferes with the practical use of the drug, it being affirmed that the night-sweats are increased for a long time after its withdrawal. It has been considerably used in acute articular *rheumatism*, though its action does not seem to be as sure or powerful as the salicylates. As an analgesic, in ataxic and neuralgic pains, it appears to be distinctly inferior to phenacetin and antipyrin. No eruption from it has been noticed. During its administration the urine responds to Trommer's test, but does not contain sugar, nor is there hæmoglobinuria. Dose for adults, seven and a half grains (0·49 Gm.).

METHETHYL. Under this name there has been offered for use in the market as a local anæsthetic a colorless neutral liquid, having a boiling point of 51° F. and a specific gravity of 0·9173 at 39° F. It is said to be ethyl chloride with a little

methyl chloride and chloroform. (*Pharm. Zeitg.*, xliii.)

METHYL CHLORIDE, *Monochlormethane*, CH_3Cl, is obtained by the action of hydrochloric acid gas upon methyl alcohol, best in the presence of a little zinc chloride.

It is a colorless gas, condensing to a liquid at —23° C. (—11·4° F.), and is very soluble in alcohol, which dissolves thirty-five volumes of it, while water dissolves four volumes. On account of its extreme volatility, methyl chloride, when applied in the form of a spray, produces extreme cold and freezing of the part. It has been used in this way as a local anæsthetic, and in 1884 Debove recommended in *sciatica* freezing by it of the parts immediately over the nerve. The practice has been tried to a considerable extent, with alleged good results. For reference, see *Union Méd. du Nord-est*, July, 1892, and *Kansas City Med. Index*, 1886.

METHYL FLUORIDE. CH_3F. M. Henri Moissan (*Bull. de l'Acad. de Méd.*, 1890) affirms that this fluoride possesses anæsthetic properties.

METHYL IODIDE. CH_3I. *Iodure de Méthyl*, Fr. *Jodmethyl*, G. This is a heavy, sweet-smelling liquid, boiling at 43° C., and has a sp. gr. 2·23 at 15° C. In the cold it unites with water to form a crystalline hydrate, $CH_3I + H_2O$. It turns brown gradually on exposure to light. It is made by the action of dry hydrochloric acid gas upon a mixture of potassium iodide and anhydrous methyl alcohol.

R. Kirk (*Lancet*, Oct. 1885) commends methyl iodide as a vesicant, applied on lint under a watch-glass, a drop or two of soda solution being added to neutralize the free iodine that may be present. It produces at once a tingling, burning, biting sensation, like pricking with a number of needle-points. The maximum pain is reached in a few minutes, when the substance is to be removed. The blister produced is said to be as full of serum as that caused by cantharides.

METHYLAL. *Methylene dimethyl ether.* $CH_2(OCH_3)_2$. This is made by distilling methyl alcohol with sulphuric acid in the presence of manganese peroxide, or by abstracting one molecule of water from a mixture of one molecule of formaldehyde and two of methyl alcohol. It is a limpid colorless liquid, of sp. gr. 0·855 at 17° C., and boils at 42° C. (107·6° F.). It is soluble in water, alcohol, ether, and fatty and ethereal oils. Originally proposed as an anæsthetic and hypnotic by B. W. Richardson in 1868. Richardson, Motrokhin, and Personali are in general accord as to its physiological action. It produces in man a sleep closely resembling the normal sleep; or, if the dose have been large enough, a profound coma in which reflex actions are suspended. Recovery is rapid on account of its rapid elimination. The arterial pressure is reduced, as is also, according to Motrokhin, the irritability of the cerebral cortex. Both Personali and Motrokhin find that it arrests the tetanic spasms produced by small doses of strychnine, although in Motrokhin's experiments, when large doses of strychnine were given, methylal seemed to accelerate rather than put off death. The dose of methylal is from one to two drachms (3·69–7·39 C.c.) given in emulsion. It is employed as an hypnotic, and is said to be free from danger and unpleasant effects; but in most cases patients become so rapidly accustomed to it that its influence soon disappears, unless enormous doses are used.

METHYLETHYLCARBINOL. $CH_3 \cdot CH(OH) \cdot C_2H_5$

There are two compounds isomeric with each other known respectively as *methylethylcarbinol* and *trimethylcarbinol*. The former is a strong-smelling liquid, boiling at from 98°–100° C.; the latter crystallizes in plates melting at 28° C. and boiling at from 83°–84° C. These alcohols are said to be vasomotor depressants and antipyretics, the dimethylethyl compounds being the more powerful of the two. (*Pharm. Post*, Jan. 1888.)

METHYLIC ALCOHOL. Spiritus Pyroxylicus Rectificatus, *Br.* 1864. Pyroligneous Spirit. *Pyroxylic Spirit. Wood Spirit. Wood Alcohol. Wood Naphtha. Alcool méthylique, Alcool formique, Alcool de Bois, Esprit de Bois, Esprit pyroligneux*, Fr. *Holzgeist, Methylalcohol*, G. $CH_3.OH$. Methylic alcohol was discovered in 1812 by P. Taylor. When wood is subjected to destructive distillation, there is formed, besides acetic acid, tar, and other products (see *Creosotum*), about 1 per cent. of an inflammable, volatile liquid, which, when separated and purified, constitutes pyroxylic spirit. The crude liquor, derived from the wood, separates on standing into two liquids; the heavier containing the tarry matters, and the lighter consisting of water, acetic acid, pyroxylic spirit, etc. The lighter liquid is saturated with lime, and subjected to distillation, whereby the impure pyroxylic spirit first comes over, mixed, however, with various compounds, among which are aldehyde and pyroacetic spirit (acetone). This, after having been redistilled and deprived of water by repeated rectifications from lime, forms the *pyroxylic spirit of commerce*. The commercial spirit may be purified by adding to it as much calcium chloride as it can dissolve, and allowing the mixture to stand for a few days. The pyroxylic spirit unites with the calcium chloride, and the compound formed is subjected to distillation to separate certain contaminating substances, which distil over. Finally, the pyroxylic spirit is separated from the calcium chloride by the addition of water and a new distillation, and from water by rectification from dry lime. Methyl alcohol, like the other monatomic alcohols, can also be formed synthetically in a variety of ways,—from marsh-gas, from formic acid, and from formaldehyde. Pure anhydrous methyl alcohol is a mobile, colorless liquid, possessing a hot, pungent taste, and a peculiar aromatic smell, recalling that of acetic ether. It mixes in all proportions with water, alcohol, and ether, without having its transparency disturbed. It burns like alcohol, but with a less luminous flame. Its sp. gr. as a liquid is 0·8021 at 15·5° C. (59·9° F.). Its vapor is irritating to the eyes. It boils at 66° C. (150·8° F.) (according to other authorities at 55° C., when absolutely anhydrous), and during ebullition its vapor causes concussions, which render its distillation difficult, but may be prevented by placing in the bottom of the vessel a layer of mercury. As a solvent it resembles alcohol, all bodies soluble in that menstruum being likewise soluble in pyroxylic spirit. Methyl alcohol is the first of a series of organic hydrates known as *alcohols*. It may be considered as a molecule of water in which one hydrogen atom is replaced by the monad group CH_3 (methyl), derived from marsh-gas (methane) by the withdrawal of one

hydrogen atom. These organic hydrates are basic, and form with both organic and inorganic acids salts called *ethers*.

The official pyroxylic spirit was directed in the Br. Pharmacopœia to have a sp. gr. from 0·841 to 0·846. From the density thus recognized, it might be implied that not the pure but the commercial pyroxylic spirit was contemplated, which has a straw-yellow color and a powerful odor of wood smoke. But the Pharmacopœia also directed that the spirit should be without action on litmus-paper, free from smoky taste, and not rendered turbid by water. It therefore intended a purified spirit, and the greater density must be ascribed to the presence of the 10 per cent. of water allowed. According to Mr. Morson, of London, the impure commercial spirit, which is unfit for medical use, may be purified "by largely diluting it with water, when an oily substance separates, after the removal of which the spirit may be recovered by distillation." By passing the mixed liquids through animal charcoal the purification is rendered more complete. Pyroxylic spirit has been confounded with pyroacetic spirit. They may be distinguished, according to Mr. Scanlan, by calcium chloride, which is without action on the latter, but dissolves in the former. In applying the test, a drop or two of a *saturated* solution of calcium chloride is added to the doubtful liquid in a test-tube. This solution is immiscible with pyroacetic spirit, separating after agitation, but dissolves instantly in pyroxylic spirit. The liquid examined must be so pure as not to separate into two layers, nor to become milky with water.

It is sometimes desirable to be able to distinguish the presence of methylic alcohol in ordinary alcohol, and in ether or nitrous ether which may have been prepared from the methylated instead of the pure spirit. For this purpose Mr. W. Young proposes a solution of potassium permanganate as a test. Dissolve a grain of the crystallized permanganate in a fluidounce of distilled water. If ten minims of this solution be added to four fluidrachms of pure alcohol in a test-tube, the bright pink color of the former fluid will be retained at least ten minutes, after which it will gradually fade. If only 10 per cent. of methylated alcohol be contained in the alcohol, the solution, instead of retaining its color for some time, will almost instantly change to a pale brown tint. With a larger proportion of the methylic alcohol, the change will be even more striking. One part of methylic alcohol can be thus readily detected in 300 of proper alcohol. The same test will detect methylic alcohol in ether and sweet spirit of nitre; but in the latter case the spirit should be purified from acid by mixing it with an equal measure of solution of potassa twice as strong as the official, and, after the mixture has stood an hour, distilling off the original measure of the nitrous spirit. (See *A. J. P.*, 1866, 58; from *P. J. Tr.*, Nov. 1865.) The test of Dumas and Péligot converts the wood spirit into a methyl oxalate; A. Riché and C. Bardy condemn this process, as not applicable when the proportion of ethylic alcohol is large, and propose a substitute founded upon the different colored products yielded by the oxidation of ethyl-aniline and methyl-aniline. For details of this process the reader is referred to *P. J. Tr.*, 1875, 1007. For a method of detecting methylic alcohol in any mixture, by Mr. John T. Miller, see *P. J. Tr.* (2d ser., vii. 318).

Under the name of *Columbian Spirit*, a purified wood alcohol has been largely introduced; its odor is less offensive than that of the crude spirit, and its cost is less than that of ethyl alcohol, but it is unfitted for making pharmaceutical preparations that are intended for internal administration, several deaths having been reported on account of its use. (*Proc. A. P. A.*, 1897, 176.)

Pyroxylic spirit, under the incorrect name of *naphtha*, was introduced some years ago by Dr. John Hastings, of London, to palliate the cough and lessen the febrile excitement of *consumption*. The therapeutic properties of pyroxylic spirit have not been fully investigated; but it is probably a narcotic sedative. D. W. Yandell speaks favorably of its efficacy in *diarrhœa* and *dysentery*. It is not improbable that the impurities in the commercial spirit may have some remedial efficacy; and the purified spirit directed by the Br. Pharmacopœia may be less efficacious than the impure. The dose is from ten to forty drops, three times a day, sufficiently diluted with water.

Crude pyroxylic spirit, varying in density from 0·846 to 0·890, is employed by hatters and varnish-makers for dissolving resinous substances, and by plumbers for burning in lamps as a substitute for alcohol. For the latter purpose it is more economical than alcohol, giving out more heat for equal weights.

In Great Britain alcohol is subjected to a heavy duty, which, until lately, prevented it from being used in many manufactures, because the products of its use can be more cheaply obtained from abroad. The British Parliament, wishing to encourage the use of alcohol in the arts, but not as a beverage, passed an act in 1855, allowing it to be used duty-free, provided it be mixed with at least one-ninth of its bulk of pyroxylic spirit, which renders it unfit for drinking, but does not spoil it for use in the arts. This mixture is called *methylated spirit*, and is now employed extensively in Great Britain by hatters, brass founders, and cabinet-makers for dissolving shellac and other resinous substances, and by manufacturing chemists for making ether, chloroform, and sweet spirit of nitre. From the purification of pyroxylic spirit already referred to, so as to deprive it of offensive taste, it has been supposed that the intended operation of the British revenue laws might be evaded; but, in opposition to this idea, it is asserted that the purifying process is too expensive, on the large scale, to render it available for the purpose. The use of this spirit, however purified, would be unjustifiable in medical preparations, unless officially recognized.

METHYLIC ETHER. $(CH_3)_2O$. *Oxide of Methyl. Hydrate of Methylene. Éther méthylique*, *Oxyde de Méthyl*, Fr. *Methyläther*, *Holzäther*, *Formäther*, G. This substance was discovered by MM. Dumas and Péligot, but was first employed as an anæsthetic by Dr. B. W. Richardson in 1867. He prepares it by mixing one part of pure methylic alcohol with two of strong sulphuric acid, heating, and collecting and washing repeatedly with strong potassa solution the methylic ether which passes over. It is a gas even at low temperature. Dr. Richardson saturates absolute ethylic ether, at 0° C. (32° F.), with it, and at once closely bottles the compound under the name of *methyl-ethylic ether*. For a detailed description of the preparation of methylic ether and of its properties, see *Journ. de Pharm.*, 4e sér., xix. 438. According to Dr. Richardson, methylic ether is a very rapid and safe

anæsthetic, producing great muscular relaxation with extreme quickness. (*A. J. P.*, Sept. 1870; *Dublin Quarterly*, Aug. 1870; *Lancet*, March, 1870.)

METHYLPHOSPHIN. Fürbringer (*Deutsch. Archiv f. Klin. Med.*, lix., 1897) has found that this substance is a powerful convulsant poison, killing when in sufficient dose by respiratory paralysis, and having very little direct influence upon the circulation. The *di-methylphosphin* was found to be very slightly more poisonous than the methylphosphin, the fatal dose being about 0·5 gramme per kilo for the rabbit. Di-methylphosphin has been used in malaria by Julius Mannaberg, in the dose of nineteen grains (1·2 Gm.) per day, but is inferior to quinine. The urine becomes dark reddish yellow and distinctly fluorescent, whilst numerous small yellow spots appear upon the skin.

METHYLTHEBAINE. $C_{20}H_{23}NO_3$. This product, from thebaine, has been physiologically investigated by Crum Brown and Fraser, and by Stockman and Dott, and found to have an action similar to that of thebaine, but less powerful. (*Brit. Med. Journ.*, Jan. 1891.)

MICHELIA NILAGIRICA. Zenker. (Nat. ord. Magnoliaceæ.) This tree, which is said to be abundant in the Neilgherry hills, India, yields an aromatic, volatile oil, which has entered commerce. (*P. J. Tr.*, Jan. 1888.)

MICROCIDIN. Under this name the varying compounds of sodium naphthalate with other naphthalates and phenates have been put upon the market, and used as a surgical antiseptic, in solution varying from three to eight parts per thousand.

MICROMERIA DOUGLASII. Benth. *Yerba Buena.* This labiate of California is said to be a grateful aromatic, and also an anthelmintic and an emmenagogue. For a description, with figures, see *A. J. P.*, Sept. 1882. Dose of fluid extract, from a half to two fluidrachms (1·84–7·39 C.c.).

MIGRAININE. A white powder, said by J. Hoffmann to be composed of 89·4 per cent. of antipyrin, 8·2 per cent. of caffeine, and 0·56 per cent. of citric acid. It is used against migraine and neuralgia in doses of sixteen grains (1 Gm.).

MILK. *Lac.* Br. Pharm. 1883. *Cow's Milk.* When examined with the aid of the microscope, milk is seen to contain a vast number of extremely small opaque corpuscles floating in a transparent liquid. These corpuscles have been found to consist of fatty matter surrounded by a very delicate coating of an albuminoid substance. To them the milk owes its opacity and whiteness; and, as they are slightly lighter than the liquid portion, they rise when the milk is allowed to stand, and form a layer on the surface, which is cream. The interior fatty matter, when caused to separate from its envelopes, aggregates in small masses, and forms butter. Thus it is that, in preparing butter, the milk is agitated, by churning or otherwise, so as to break the corpuscular coating. But in the formation of both cream and butter the residuary liquid still contains a number of unbroken corpuscles, which give it more or less whiteness; and in skimmed milk, notwithstanding the quantity of corpuscles lost, enough remains to give it almost the whiteness and opacity of the milk just from the cow. It has been denied that the corpuscles are really enveloped by a distinct membrane; but the effect of mechanical agency in the preparation of butter seems to afford indisputable proof of the existence of a coating which is broken in the process; and there is chemical proof which would appear to be not less decisive. Ether dissolves the fatty matter constituting butter; and if a liquid, having oil globules floating in it free, be agitated with ether, the oily matter is dissolved, and the liquid quite deprived of it. Now, if milk be agitated with ether, and the mixture be allowed to stand, the two liquids separate, and the ether rises in consequence of its levity, and floats unaltered on the surface. But if, before the addition of ether, acetic acid, which dissolves the envelopes of the fatty matter, be made to act on the milk, the interior fatty matter of the corpuscles is set free; and then ether added to it takes up the butter thus liberated.

The composition of a normal cow's milk and, for comparison, the milk of other mammalia is thus given by Blyth (*Foods, Compos. and Analysis*, 1882, 214):

	Cow's.	Human.	Ass's.	Goat's.	Mare's.	Sheep's.	Sow's.	Bitch's.
Milk fat	3·50	2·90	1·02	4·20	2·50	5·30	4·55	9·57
Casein	3·98	2·40	1·09	3·00	2·19	6·10	7·23	5·53
Albumen	0·77	0·57	0·70	0·62	0·42	1·00		4·38
Galactine	0·17	0·10	0·10	0·08	0·09	0·13		
Sugar of milk	4·00	5·87	5·50	4·00	5·50	4·20	3·13	3·19
Ash	0·70	0·16	0·42	0·56	0·50	1·00	1·05	0·73
Water	86·87	88·00	91·17	87·54	88·80	82·27	84·04	76·60
Total solids	13·13	12·00	8·83	12·46	11·20	17·73	15·96	23·46

The following method of estimating the quantity of the different ingredients in milk is given by Dr. C. F. Chandler, of New York. 1. The water may be determined by evaporating a weighed quantity of milk, drying the residue carefully at 100° C. (212° F.), and weighing what remains. The loss represents the water. 2. The salts are estimated by burning all that is combustible in the solid residue, and weighing the ash. 3. To ascertain the proportion of butter and casein, a portion of milk, having been coagulated by a few drops of acetic acid, is boiled; the precipitate is washed with water, and finally the butter is separated by ether, leaving the casein behind. The ethereal solution yields the butter on evaporation. 4. The sugar is generally estimated by deducting the weight of the other ingredients from 100. The fatty matter of milk, or butter, consists of stearin, palmitin, and olein, with small proportions of butyrin, caproin, and caprin, to which it owes its smell. Butyrin is a compound ether of butyric acid and glyceryl, and is inodorous. On exposure of butter for some time to air, the butyrate of glyceryl is decomposed, and the butyric acid, being

set free, causes the disagreeable odor characteristic of rancid butter. The proportion of fatty matter in milk is estimated by Mr. John Horsley by means of the joint solvent powers of alcohol and ether, the mixed menstrua being allowed to stand, and the oil as it rises to the surface removed. For minute particulars, see the *Chemical News*, May 2, 1874. The casein of milk is a peculiar and most important ingredient, bearing a close resemblance to animal albumen, but differing from it slightly in composition, and also in some of its chemical relations with other substances. A little phosphorus is contained in albumen, which has not been found in casein. (*Chem. News*, Jan. 7, 1870, 6.) Nevertheless, there is reason for believing that casein is the source of all the albuminoid substances in the body when supported by milk alone. The sugar of milk is peculiar. (See *Saccharum Lactis.*)

For the purpose of preserving milk various methods have been devised, several of which are discussed in the 17th ed. *U. S. D.* They have all, however, been rendered effete by the extensive manufacture of *condensed milk* by more or less secret processes, which are probably all based upon the method of M. Martin de Lignac. Milk immediately from the cow is put in shallow boilers with a flat bottom, to the depth of about two inches, and heated by a water-bath. For every pint of milk an ounce of white sugar is added; and, so long as the heat is continued, the contents of the boilers are constantly stirred, so as to favor evaporation. When the volume is reduced four-fifths, the concentrated liquid is poured into cylindrical cans, the opening of which is hermetically closed by tin solder. The cans are arranged in a boiler constructed like a steam-boiler, so as to support a pressure within, and vapor is introduced at the temperature of from 103·5° to 104° C. (218°–219° F.). As soon as the boxes have thus been exposed to heat, the preparation is completed. When the can is opened, it will be found to be filled with a pasty substance, somewhat translucent, and yellowish white. Diluted with five times its weight of water, this substance has all the exterior and nutritive characters of ordinary milk. When thus exposed, the milk will keep readily ten days or more, especially if a little be taken every day from the can, so as to change the surface in contact with the air. The sugar used contributes to the preservation of the milk. The high temperature employed for a short time contributes greatly to the same end, by destroying the ferments which may be in the milk. M. Payne recommends, when the taste of boiled milk is objectionable, that the evaporation be carried on *in vacuo* by means of vapor, aided by agitation with mechanical stirrers. (*Journ. de Pharm.*, Mars, 1868, 195.) Condensed milk is now consumed in our country on an enormous scale. Unfortunately, a great deal of it is adulterated with white cane-sugar, which, from being first used moderately as a preservative, is now largely employed as a make-weight. The composition of this condensed milk may be seen from the following analyses of well-known brands taken from Sadtler's *Industrial Org. Chem.*, p. 260:

Brand.	Water.	Fat.	Cane- and Milk-sugar.	Casein.	Salts.
Alderney	30·05	10·08	46·01	12·04	1·82
Anglo-Swiss (American)	29·46	8·11	50·41	10·22	1·80
Anglo-Swiss (English)	27·80	8·24	51·07	10·80	2·09
Anglo-Swiss (Swiss)	25·51	8·51	53·27	10·71	2·00
Eagle	27·30	6·60	44·47	10·77	1·86
Crown	29·44	9·27	49·26	10·11	1·92

Milk is liable to various changes which more or less diminish its value as food or medicine, and therefore require to be guarded against. One of these is spontaneous, occurring on the exposure of milk to the air, and at an earlier or later period after being drawn from the cow, according to the weather: the greater the heat the surer and greater will be the amount of change. The milk becomes sour to the taste and smell, imperfect coagulation takes place, the envelope opens, and the oil escapes; and altogether the milk becomes unfit for use. Against such alterations the milk may be protected if kept in closed glass jars, so as to exclude the air; and it is desirable to keep the jars, to some extent, in as cold a place as convenient. There is another injurious change to which milk is often exposed, sooner or later after being taken from the cow,—that is, the presence in it of various organic germs or growths, derived generally from the atmosphere.

Sterilization of Milk. Milk may be deprived of organisms or sterilized by the application of the heat of boiling; a temperature of 100° C. (212° F.) will destroy all bacteria, but a somewhat lower temperature is usually sufficient, and a *pasteurized milk* is one which has been subjected to a temperature of from 155° to 170° F. for ten or twenty minutes. It has the advantage of tasting less like boiled milk and of being more digestible than such sterilized milk. The following simple method of pasteurizing milk has been issued by the U. S. Department of Agriculture: "Take a tin pail and invert a perforated tin pie-plate in the bottom, or have made for it a removable false bottom perforated with holes and having legs half an inch high to allow circulation of the water. The milk-bottle is set on this false bottom, and sufficient water is put into the pail to reach the level of the surface of the milk in the bottle. The pail is then heated on a range or stove. A hole may be punched in the cover of the pail, a cork inserted, and a chemical thermometer put through the cork, so that the bulb dips into the water. The temperature can thus be watched without removing the cover. If preferred, an ordinary dairy thermometer may be used and the temperature read from time to time by removing the lid. This is very easily arranged, and is just as satisfactory as the patented apparatus sold for the same purpose."

There can be no doubt that, by being exposed to putrescent effluvia and otherwise bad air, or derived from a diseased cow, milk may become in-

fected with noxious matter, whether chemical or organic, and may thus, when used as food, be the cause of serious disease. Typhoid fever has in a number of cases been produced by infected milk.

Adulteration. Milk is liable to adulteration. The most common, and perhaps the most important, is dilution with water. This, within certain limits, is very easily effected, is very difficult to discover, and, moreover, is very profitable from a pecuniary point of view. The temptations to its practice are so great and universal that constant watchfulness is necessary to one who would guard himself against it. Very copious addition of water is recognized at once by the thinness, blueness, and in some degree the translucency of the milk. But much adulteration may take place short of this; and to detect the fraud it is necessary to prove a decided excess of water; for even in perfectly normal milk there is often some disproportion of this ingredient above or below the mean, owing to the mode of living and health of the cow. This deviation, however, is small. Observations made in Sweden by Alexander Müller and Eisenstuck, on a herd of fifteen cows, with daily analysis in every case throughout the year, resulted in the statement that the solids of the milk in no instance fell short of 11·5 per cent., and in only four instances below 12; while the highest was 14·05; the average being 12·8 per cent. In England, of ten cows, from different parts of the country, the milk of which was examined by Mr. J. Alfred Wanklyn, that of only one contained so little as 11·8 per cent., while the highest was 14·34, and the mean was 12·7. With the aid of these figures it will be easy to detect any considerable amount of adulteration by water; for all besides the amount of solids may be considered as consisting of this fluid. All that is necessary, therefore, is to weigh very carefully a given quantity of milk, say 1000 grains, in thin platinum or silver dishes, and maintain it by means of a water-bath at the temperature of 212° F. for three hours, or until evaporated to dryness. The residue when weighed will give the amount of the solids, and the difference between it and the 1000 grains will be the weight of the water. If the solids fall short of 11·8, the proportion of the deficiency to the whole weight of the milk may be considered as representing the quantity of water added. Other methods of estimating the proportion of water in excess have been based on the specific gravity of the milk, which it was supposed would be lighter than the normal. Upon this principle it was that lactometers were formed. But it has been found that this method is not entirely reliable, as the specific gravity of the milk varies with other causes besides an excess of water; for the removal of the cream increases the density of the milk, the former being the lighter of the two. We are informed that annatto dissolved in a strong potash lye, termed *butter color*, is extensively used to impart a yellow color and apparent richness to milk. Starch or farinaceous substances have been employed apparently for giving substance to milk rendered too fluid by dilution. This may be detected by the usual reagent for starch; but it must be recollected that when iodine is added to milk containing starch it acts on the latter only after the milk has been completely saturated with the iodine, after which the blue color is produced by a further addition of the reagent. Chalk has, we believe, been used in the adulteration of milk, in like manner with the starch, for giving it whiteness and increasing its opacity; but this and all similar mineral bodies may be detected by their subsidence, if insoluble, and by their remaining behind when the milk is incinerated, if more or less soluble. Many methods have been proposed for testing milk. On account of want of space, the reader is referred for further information to the following accessible sources: *A. J. P.*, 1872, 1873, 1874, 1878, 1879; and *N. R.*, 1875, 1876, 1877, 1880, 1881.

Few remedies are more important than milk for the sick, considered in its relations either as an article of food or as a medicine. In the former capacity, its easy digestibility, nutritious character, and entire want of stimulant or irritant properties render it peculiarly useful, as an exclusive article of diet, in many cases of chronic irritation or inflammation of the alimentary mucous membrane. In obstinate *chronic diarrhœa*, *chronic dysentery*, and *chronic gastritis* it will sometimes effect cures, as an exclusive diet, with but little aid from medicine. As a remedy in *nausea* and *vomiting*, either alone or attendant on other diseases, milk associated with lime water in the dose of a tablespoonful of each every half-hour, one, or two hours, according to the severity of the case, has long been esteemed one of our most efficient remedies. In the form of wine-whey it has from time immemorial been used as a gentle stimulant, applicable to febrile diseases beginning to assume a low form; and still later, in conditions of great debility, it is, with brandy, the remedy upon which reliance is placed beyond all others. For the mode of preparing and using wine-whey, see the article on *Vinum*.

MISTURA MAGNESIÆ ET ASAFŒTIDÆ. *U. S.* 1880. *Mixture of Magnesia and Asafetida. Mixture de Magnésie et d'Asafétide*, Fr. *Magnesia und Stinkasant-Mixtur*, G. This preparation, which has had some popular vogue under the name of *Dewees's Carminative*, was directed by the *U. S. Pharmacopœia* of 1880 to be made as follows. "Carbonate of Magnesium, *five parts* [or three hundred and sixty grains]; Tincture of Asafetida, *seven parts* [or ten fluidrachms]; Tincture of Opium, *one part* [or seventy-five minims]; Sugar, *ten parts* [or one and a half ounces av.]; Distilled Water, *a sufficient quantity*, To make *one hundred parts* [or fifteen fluidounces]. Rub the Carbonate of Magnesium and Sugar, in a mortar, with the Tincture of Asafetida and Tincture of Opium. Then gradually add enough Distilled Water to make the mixture weigh *one hundred parts* [or measure fifteen fluidounces]." There is but 1 per cent. of tincture of opium in the formula just given, whilst the usual quantity is 3 per cent. The dose is twenty minims (1·25 C.c.).

MITCHELLA REPENS. L. *Squaw Vine. Partridge-berry. Checkerberry. Winter Clover.* (Nat. ord. Rubiaceæ.) This small indigenous evergreen has been supposed to possess remedial properties, and is said to be employed, in decoction, by the Indian squaws, to facilitate parturition. It appears to be diuretic, tonic, and astringent, resembling in these respects the pipsissewa, for which it is often substituted. E. Breneiser (*A. J. P.*, 1887, 228) found it to contain some resin, wax, mucilage, dextrin, and what appeared to be saponin.

MOLLIN is a base for ointments that has attracted some dermatological notice in Germany.

It is a soft soap, containing 17 per cent. of uncombined fat, and is stated to be prepared by saponifying without heat 100 parts of cocoa-nut oil or of fresh fat with 40 parts of solution of caustic potash, sp. gr. 1·145, mixing intimately with 30 parts of glycerin, and heating carefully. It is yellowish white, of a smooth and soft consistence, not readily altered by exposure, free from rancidity, and easily removed from the skin by warm or cold water.

MOMORDICA BALSAMINA. L. *Balsam Apple. Balsamina.* (Nat. ord. Cucurbitaceæ.) An annual climbing East Indian plant, cultivated in our gardens for the sake of the fruit. This is ovate, attenuated towards each extremity, angular, warty, not unlike a cucumber in appearance, of a lively red or orange-yellow color, easily falling when touched, and spontaneously separating into several pieces. It was formerly highly esteemed as a vulnerary, and is still in use among the common people. A liniment formed by infusing the fruit, deprived of its seeds, in olive or almond oil, is applied to *chapped hands*, *burns*, *piles*, *prolapsus ani*, etc.; and the fruit itself is sometimes mashed, and used in the form of a poultice. According to M. Descourtilz, it is poisonous when taken internally, having proved fatal to a dog in the quantity of two or three drachms. An extract prepared from it is said to be useful in *dropsy*, in the dose of from six to fifteen grains (0·4–0·9 Gm.).

MONARDA PUNCTATA. L. *Horsemint. Menthe de Cheval*, Fr. *Pferdeminze*, G. This is an indigenous perennial or biennial labiate, with herbaceous, obtusely angled, downy, whitish, branching stems, rising one or two feet in height, and furnished with oblong lanceolate, remotely serrate, smooth punctate leaves. The flowers are disposed in numerous whorls, provided with lanceolate, white or purplish-colored bracts, longer than the whorl; the corolla is yellow, spotted with red or brown. The horsemint grows in light gravelly or sandy soils from New York to Louisiana and west to Wisconsin, and flowers from June to September. The whole herb is employed. It has an aromatic smell, and a warm, pungent, bitterish taste, and abounds in a volatile oil, which may be separated by distillation with water. A crystalline stearopten, at first named *monardin*, often separates from the oil (Procter, *A. J. P.*, xvii. 86): it is now known to be thymol, $C_{10}H_{14}O$. Herman J. M. Schroeter (*A. J. P.*, 1888, 120) found the oil to consist of a hydrocarbon, $C_{10}H_{16}$ (50 per cent.), thymol, $C_{10}H_{14}O$ (25 per cent.), and higher oxygenated compounds, $C_{10}H_{18}O$. Kremers (*Pharm. Rev.*, 1896, 223) examined the oil from authentic specimens and found it to yield from 56 to 61 per cent. of a phenol (thymol). Horsemint is stimulant and carminative, but is seldom used in regular practice. In the state of infusion it is occasionally employed in families as a remedy for flatulent *colic* and sick stomach, and for other purposes to which the aromatic herbs are applied. *Monarda fistulosa*, L., also an American plant, is said to be a very active diaphoretic. (See *Proc. A. P. A.*, 1895, 256; 1896, 238.)

MONESIA. A South American vegetable extract, which is believed to be derived from the bark of *Chrysophyllum glycyphlœum*, Casar (now known as *Lucuma glycyphlœa*, Mart. and Eichl. et Miq.) (nat ord. Sapotaceæ), a tree of moderate size, growing in the forests near Rio Janeiro and elsewhere in Brazil. (*Journ. de Pharm.*, 3e sér., vi. 63.) The bark, which has also entered commerce, is in pieces, some of which are three or four lines thick, is very compact and heavy, of a deep brown or chocolate color, contrasting strongly with the grayish color of the epidermis when this remains, and of smooth fracture. The extract was received from South America in cakes weighing rather more than a pound, from three-quarters of an inch to an inch in thickness, of a dark brown almost black color, very brittle, of a fracture neither very dull nor very shining, and of a taste at first sweet, then astringent, and ultimately acrid; the acrimony being very persistent, and especially felt in the fauces. It is entirely soluble in water. The bark was found by Derosne, Henry, and Payen to contain, in one hundred parts, 1·2 of stearin, chlorophyll, and wax, 1·4 of glycyrrhizin, 4·7 of an acrid principle analogous to saponin, called *monesin*, 7·5 of tannic acid, 9·2 of a red coloring substance, 1·3 of malic acid and malate of calcium, 3·0 of various salts, including silica and oxide of iron and manganese, and 71·7 of pectic acid or pectin and of lignin, including loss, besides traces of an aromatic principle and of gum. A more recent analysis by Dr. Peckolt (*A. J. P.*, 1884, 626) gives *monesiatannic acid*, which gives a black coloration with iron salts, gallic acid, *monesin*, an acrid, amorphous body, *lucumin*, a body crystallizing in silky needles, a bitter substance, glycyrrhizin, tartaric and citric acids, wax, etc. *Monesin*, which is now considered as identical with saponin, $C_{32}H_{54}O_{18}$, was obtained by treating the bark or extract with alcohol, adding to the tincture an excess of calcium hydrate in fine powder, filtering, evaporating the clear liquor to dryness, treating the residue with water and animal charcoal, filtering, and again evaporating to dryness. Thus procured it was in transparent yellowish scales, which were easily pulverized, forming a white powder. It was uncrystallizable, readily soluble in alcohol and water, to the latter of which it gave the property of frothing, and insoluble in ether. It had no power to saturate acids, was without odor, but had a slightly bitterish taste, followed by a decided and permanent acrimony in the posterior mouth and fauces. (*Journ. de Pharm.*, Jan. 1841.) Monesia owes its activity probably to this principle and to tannic acid.

The effects of this medicine upon the system appear to be those of a moderate stomachic excitant, a general alterative, and a feeble astringent. In overdoses it is said to produce heat in the epigastrium, with obstinate constipation and tenesmus. It has been used internally with asserted advantage in *diarrhœa*, *hæmoptysis*, *menorrhagia*, *scrofula*, *scurvy*, the chronic *catarrh* of old people, and *dyspepsia*. As a local remedy it has been found useful in *leucorrhœa*, *ulcerations of the mouth and fauces*, *spongy* and *scorbutic gums*, *carious teeth*, and obstinate scrofulous and otherwise unhealthy *ulcers* upon the surface. The dose of the extract is from two to ten grains (0·13–0·65 Gm.), repeated every one to three hours. From ten grains to a drachm may be given daily. In scrofulous affections it must be used in large quantities, and persevered in for several weeks, in order to obtain its curative effects. Monesia is applied to ulcers either by being sprinkled in powder upon the surface or in the form of ointment made with one part of the

extract and seven parts of simple ointment. Monesin has been given internally in the dose of about half a grain, and has also been applied to ulcers. It is said to be a powerful oxytocic.

MONGUMO BARK. For analysis of this Madagascar bark, see *P. J. Tr.*, ix. 816.

MONOBROM - ACETANILID. *Asepsin.* $C_6H_4Br.NH(C_2H_3O)$. This substance, which has been proposed as a substitute for antifebrin, forms colorless monoclinic prisms, melting at from 165°–166° C., scarcely soluble in water, easily soluble in hot alcohol. Dr. Worthington (*Brit. Med. Journ.*, Feb. 1890) has reported two cases in which cyanosis and collapse were produced by it.

MONSONIA. According to John Maberly (*London Lancet*, Feb. 1897, July, 1898), certain South African plants belonging to the family of Geraniaceæ, having large fleshy roots, are valuable remedies in the treatment both of acute and chronic *dysentery;* such are especially *Monsonia ovata*, Cav., and *Monsonia burkeana*, Planch., ex Harv. and Lond.; also certain Pelargoniums. Under the name of *t'Namie*, the natives of Namaqualand are said to use the root of *Pelargonium antidysentericum*, Kostel. Maberly believes that the Pelargoniums are especially valuable in ulceration of the stomach and upper portions of the intestinal tract; and the Monsonias when the disease is low down in the intestines. The dose of monsonia is given as half an ounce (15·5 Gm.). It is believed that the plants are not poisonous. Dose of the saturated tincture from one to two fluidrachms (3·7–7·5 C.c.) every three or four hours.

MORINDIN. This principle, discovered by Anderson in *Morinda citrifolia*, L. (nat. ord. Rubiaceæ), and supposed to be identical with ruberythric acid, is said to be distinct. (*P. J. Tr.*, Dec. 1886.)

MORINGA PTERYGOSPERMA. Gaertn. (Nat. ord. Moringeæ.) A decoction of the root of this Jamaica tree is said to be used by the peasantry as an active and persistent diuretic. (*The Satellite*, Feb. 1890.)

MOXA. *Moxa*, Fr. *Brenncylinder*, G. The term *moxa* is employed to designate small masses of combustible matter, intended, by being burnt in contact with the skin, to produce an eschar. They are of various forms, and made of different materials. The Chinese moxa is in small cones from eight to twelve lines in height, and is prepared from the leaves of one or more species of Artemisia. *A. chinensis*, L., and *A. indica*, Willd. (now *A. vulgaris*, L.), were indicated by the Dublin College; but Lindley states that it is the *A. moxa* of De Candolle which is employed. According to some authors, the part used is the down which covers the leaves and stems; but others, with greater probability, assert that it is a fine lanuginous substance, prepared from the leaves by beating them in a mortar. A coarser and a finer product are obtained, the former of which is used for tinder, the latter worked up into moxa. A similar moxa has been made in France, by a similar process, from the leaves of *A. vulgaris*. By Percy, the stem of the *Helianthus annuus*, or common sunflower, when perfectly mature, is cut into transverse sections about half an inch in thickness, which must be carefully dried, and kept in a perfectly dry place. They have this advantage, that, in consequence of the retention of the cortical portion, they may be held with impunity between the fingers of the operator, while burning. They are, however, often defective from an insufficiency of nitre in the pith, or the unequal inflammability of different parts. Artificial moxas are best made from cotton impregnated with nitre. It is important that the impregnation should be uniform; as otherwise different parts of the cylinder, burning with different degrees of rapidity, would produce unequal effects upon the skin. The following process is recommended. One pound of cotton is introduced into a vessel containing two ounces of nitre dissolved in half a gallon of water, and a moderate heat applied till all the liquid is evaporated. The cotton, when perfectly dry, is formed into thin, narrow sheets, which are rolled round a central cord of linen, so as to form a cylinder from half an inch to an inch in diameter, and several inches long. This is enclosed in a covering of silk or linen sewed firmly around it; and, when used, may be cut by a razor into transverse slices a few lines in thickness. By leaving a hole in the centre of the cylinder, the combustion will be rendered more vigorous, and a deeper eschar produced. Robinet rolls cotton round a small central cylinder of pith and envelops the whole in a piece of muslin, which is more or less firmly applied, according to the degree of compactness required. The cylinders, thus made, burn without assistance, uniformly, and with a rapidity proportionate to their firmness. Lime, in the act of slaking, has been used as a substitute for the moxa. (*Dubl. Journ.*, Jan. 1842.)

Cauterization by fire, in the treatment of disease, has been commonly practised among savage and half-civilized nations from the earliest periods of history, and has not been unknown as a remedy in the most polished communities. The ancient Egyptians and Greeks were acquainted with the use of moxa; and in China, Japan, and other countries of Asia it appears to have been employed from time immemorial. From these countries the early Portuguese navigators introduced it into Europe; and the term *moxa* is said to have been derived from their language, though supposed by some to be of Chinese origin. The true Chinese name is said to be *kiew*. Some years since, the remedy became very popular in France, and attracted some attention in this country. It acts on the principle of revulsion.

As a rule the moxa should be applied as near as possible to the seat of the disease; and, in neuralgic or paralytic cases, at the origin or over the course of the nerves proceeding to the part affected. Some advise that the cylinder be attached to the skin by some adhesive liquid; but a more general practice is to retain it in the proper position by a pair of forceps or other instrument. Larrey recommends that the skin around it be covered with a piece of moistened lint, having a hole in the centre to admit the base of the cylinder. The moxa should be set on fire at the summit, and the combustion sustained if necessary by the breath, the blow-pipe, or the bellows. The size of the cylinder should vary according to the effect desired, from half an inch to an inch or more in diameter, and from a few lines to an inch in height. Any degree of effect may be obtained, from a slight inflammation to the death of the skin, by regulating the time during which the moxa is allowed to burn. When a slough is required, it should be suffered to burn until consumed. The first sensation experienced is not disagreeable; but the opera-

tion becomes gradually more painful, and towards the close is for a short time very severe. The pain could probably be prevented by the use of cocaine.

MUAWIN BARK. This is the bark of a Mozambique tree, which in Eastern Africa is used as an "ordeal" poison. In appearance and structure it closely resembles the Erythrophlœum bark. An alkaloid, *muawine*, was discovered in it by E. Merck, 1891. So far it has been obtained only in the form of a thick, syrupy liquid, easily soluble in alcohol, ether, and chloroform. The characteristic test is said to be that with vanadin-sulphuric acid, which gives with muawin first a pale green, passing into a pale blue. (H. Jacobsohn, *Inaug. Diss.*, Dorpat, 1892; see also *Merck's Jahresbericht*, 1891.) According to Jacobsohn, the hydrobromate when injected subcutaneously does not cause any irritation, but produces in frogs symptoms similar to those caused by digitalin; and in warm-blooded animals slowing of the pulse, increase of the heart action, elevation of blood-pressure, and contraction of the arterioles. The action of muawin is, therefore, like that of digitalin, but is distinguished by being very temporary.

MUCUNA PRURIENS. De Cand. *Dolichos Pruriens*, L. *Stizolobium Pruriens.* Medic. *Cowhage. Cowage. Setæ Siliquæ Hirsutæ. Pois velus, Pois à gratter*, Fr. *Kratzbohnen, Kuhkrätze*, G. This is a leguminous perennial climbing plant, with an herbaceous branching stem, which twines round the trees in its vicinity, and rises to a considerable height. The leaves are pinnately trifoliate, and stand on long footstalks, placed alternately on the stem at the distance of a foot from each other. The leaflets are acuminate, smooth on their upper surface, and hairy beneath. The lateral leaflets are oblique at the base, the middle one somewhat rhomboidal. The flowers, which resemble those of the pea in form, are large, of a red or purplish color, usually placed in threes on short peduncles, and hang from the axils of the leaves in pendent spikes about a foot in length. The fruit is a coriaceous pod, shaped like the Italic letter *f*, about four inches long, and covered with brown bristly hairs, which easily separate, and when handled stick in the fingers, producing an intense itching sensation. The plant is a native of the West Indies and other parts of tropical America. It has been supposed to grow also in the East Indies; but the plant of that region is now considered a distinct species, and entitled *Mucuna prurita*, Hook. The part usually imported is the pod, of which the hairs were formerly official.

The spicula are said to be very destructive to the *round worm*, acting mechanically by penetrating their bodies. Neither the tincture nor the decoction is effective. The medicine was first employed in the West Indies, and thence passed into British practice. It is efficient, but so disagreeable that it has passed out of vogue. The usual mode of preparing it is to dip the pods into syrup or molasses, and scrape off the hairs with the liquid, which is in a proper state for administration when it has attained the consistence of thick honey. The dose of this preparation is a tablespoonful for an adult, a teaspoonful for a child three or four years old, to be given every morning for three days, and then followed by a brisk cathartic. The root of *M. pruriens* is said by Ainslie to be employed in the East Indies in *cholera*, and, with the pods, has been thought to possess diuretic properties.

MUIRA-PUAMA. The wood of a Brazilian tree of unknown botanical affinity, which is said to be an extraordinarily powerful aphrodisiac, and to contain an alkaloid. (*Bull. of Pharm.*, Nov. 1892.)

MULBERRY. There are in the United States three species,—the indigenous *Morus rubra*, L., with red fruit; *M. alba*, L., originally from China, and now extensively cultivated as a source of food for the silk-worm, having a white fruit; and *M. nigra*, L., a tree of middle size, supposed to have been brought originally from Persia into Italy and thence spread over Europe and America. The fruit of the last species has a sweet, mucilaginous, acidulous taste, and abounds in a deep red juice having the sp. gr. 1·060. (*Mori Succus*, Br. 1885.) In an analysis made by H. Van Hees, 100 parts of mulberries yielded the following percentage results: glucose and uncrystallizable sugar, 9·19; free acid (supposed to be *malic* with admixture of *tartaric*), 1·86; albuminous matter, 0·39; pectic matter, fats, salts, and gum, 2·03; ash, 0·57; insoluble matters (the seeds, pectose, cellulose, etc.), 1·25; water, 84·71. In amount of grape sugar the mulberry is surpassed only by the cherry, 10·79, and the grape, from 10·6 to 19·0. Mulberries are refreshing and laxative, and serve to prepare a grateful drink well adapted to febrile cases.

MUREXIDE. $C_8H_4(NH_4)N_5O_6 + H_2O$. A fine purple dye-stuff, made by the reaction of nitric acid on uric acid. As resulting from the action of nitric acid on urine, it was supposed by Prout to consist of purpuric acid and ammonia (which belief has been confirmed by further investigation), and hence was named *purpurate of ammonium*. It is now made from guano. This is first treated with hydrochloric acid to remove foreign substances, and then with soda to dissolve the uric acid, which is separated by neutralizing the soda with hydrochloric acid. The uric acid is dissolved in nitric acid, the solution is heated, and after it cools ammonia or its carbonate is added, which develops the purple color. Murexide is obtained in crystals, which have a square form, and are of a rich green color by reflected, but of a purple-red by transmitted light. They are slightly soluble in cold water, more so in boiling water, and insoluble in alcohol and ether. With potassa they form a rich purple solution. It has been replaced as a dye by aniline colors.

MUSCARI COMOSUM. L. *Hyacinthus comosus*, L. (Nat. ord. Liliaceæ.) In the bulbs of this plant Curci (*Rép. de Pharm.*, March, 1889) has found *comosic* acid, which he believes to act physiologically like saponin

MUSCULUS VENENOSUS. That certain mussels, or that mussels in certain condition, are actively poisonous is well ascertained. Dr. F. Crumpe (*Dublin Quart. Journ.*, Oct. 1873) has reported collapse with complete paralysis of the voluntary muscles as produced by the mussel, and has also treated traumatic tetanus successfully with raw mussels. M. Brieger (*Deutsche Med. Wochensch.*) has isolated certain bases out of mussels. He thinks the most important is *mytilotoxine* ($C_6H_{15}NO_2$), which he has demonstrated to possess physiological properties closely resembling those of curare. These poisonous principles are all probably ptomaines, and disappear when the mussel is boiled with sodium carbonate; so that boiling the mussel in an alkaline solution (three and a half grammes per litre of water) renders it harmless.

MUSHROOMS AND TOADSTOOLS.

(*Edible and Poisonous Fungi.*) Notwithstanding the fact that it has been shown that edible fungi, when compared with other articles of food, do not possess a high food value, the interest in the study of the fungi, as well as the consumption of edible forms, is constantly increasing. The study of the fungi is one of the most highly specialized, as there have been up to the present time no less than 39,000 species described. From a food stand-point it is one of the most dangerous that the novice can enter, as it is almost impossible to lay down any rules which can with certainty always be safely pursued.

The fungi are divided into a number of classes, each of which is again subdivided into sub-classes, series, and families. The family Hymenomycetes (consisting of more than 8000 species) includes all of the "Mushrooms" and "Toadstools." It is commonly believed that mushrooms are edible and that toadstools are poisonous; in reality, however, no such distinction should be made, as they are one and the same thing. The plants of the Hymenomycetes are characterized in general in that they arise from a mass of colorless threads, known as "mycelium" or "spawn," produced in the ground, bark of trees, etc. Their first appearance above ground is marked by the production of small solid balls (called buttons), which gradually enlarge, and at length shoot up into a stem or stipe bearing at its summit the umbrella top or "pileus," which is at first closed around the stalk like a closed umbrella and then expands more or less widely, according to the species. The under side of the pileus is the part which bears the spores, which correspond to the seeds of higher plants. In some cases the under surface consists of a series of gills resembling knife-blades, which radiate from the top of the stalk to the circumference, like the spokes of a wheel, as in Agaricaceæ; in others it consists of a mass of small pores or tubes packed closely together, side by side, as in Polyporaceæ; in others of teeth, as in Hydnaceæ; in others only slightly wrinkled or undulated, as Thelephoraceæ, etc. The Hymenomycetes are divided into six orders, viz.:

(1) *Agaricaceæ* (the mushrooms and toadstools proper) comprises about 4600 species, some of which are poisonous, as the Amanitas (Fly Mushrooms), Lactarius (with a milky juice), whereas others are edible, as *Agaricus* (Psalliata) *campestris*, L., the common mushroom, *Cantharellus cibarius*, Fr., etc.

(2) *Polyporaceæ* (Pore-Fungi) includes about 2000 species, many of which are parasites on trees and destructive to timber; some are edible, as *Boletus edulis*, Bull., whereas others are poisonous, as *B. satana*, Lenz.

(3) *Hydnaceæ* (Teeth-bearing Fungi); most of the species are too small and woody to be eaten. *Hydnum repandum*, L., forms "fairy rings" in woods.

(4) *Thelephoraceæ;* most of the species are small, and the larger species are tough and leathery.

(5) *Clavariaceæ* (Coral-shaped Fungi) includes some large fungi; none are poisonous and some, as *Clavaria flava*, Schaeff., are palatable.

(6) *Tomentellaceæ* are the simplest of the Hymenomycetes. They generally form leathery coverings on bark and wood and some are parasites.

The *Common Mushroom* (*Agaricus campestris*, L.) is practically the only species cultivated in this country, and is the only fresh species sold in the Northern markets during the winter months. It is found wild in open grassy fields or pastures in great abundance in August and September. It is not common in the mountains, never found in woods, and never grows on trees or fallen trunks. The color of the stalk and pileus varies from whitish to a shade of drab, but the *color of the gills, a point which must never be overlooked, is at first pinkish and then a brownish purple.* This color is due to the spores, which are borne on the gills. The *stalk is cylindrical and solid, and has*, rather more than half way up, *a membranous collar* called the *ring;* but there is no membrane or scales found at the base of the stalk, which appears to come directly out of the ground. "In specimens which are not fully expanded there is a thin membrane or veil which extends from the stalk to the margin of the pileus. When the veil is ruptured, exposing the gills behind, a part remains attached to the stalk, forming the ring already referred to. In older specimens the ring shrinks, but generally a mark remains showing where it has been attached." Two of the most common poisonous forms resembling the common mushroom, and which have been eaten by mistake for it, are the deadly agaric and the fly agaric.

The *Fly Agaric* (*Amanita muscaria* (L.), Pers.), so called because decoctions have been used for killing flies, is in some localities much more abundant than the common mushroom. It is seldom found in the grassy pastures preferred by the common mushroom, but more generally in poor soil, especially in groves of coniferous trees. "It grows singly and not in groups, and differs from the common mushroom in having *gills which are always white*, never pink or purple, and in having *a hollow stem*, which is *bulbous at the base and clothed with irregular fringy scales on all the lower part.* The pileus varies in color from a brilliant yellow to orange and a deep red, the yellow and orange being more frequent than the red. The *surface is polished and has scattered over it a larger or smaller number of prominent, angular, warty scales*, which can be easily scraped off. The gills and stalks are white, and there is a large membranous collar which hangs down from the upper part of the stem."

The *Deadly Agaric* (*Amanita phalloides* (Pers.), Fr.), so named because it probably has been more frequently the cause of death than any other fungus, prefers a damper and less sandy soil than the fly agaric and is not pre-eminently an inhabitant of grassy pastures. "The pileus is often a shining white, but may be of any shade from a dull yellow to olive, and when wet is more slimy than the common mushroom or the fly agaric. It has no distinct scales and only occasionally a few membranous patches on the pileus. The *gills and stalks are white, and the latter has a large ring like the fly agaric and is hollow*, or, when young, is loosely filled with cottony threads, which soon disappear. The base of the stalk differs from that of the fly agaric in being more bulbous and in having the upper part of the bulb bordered by a sac-like membrane called the volva. The volva is often of considerable size, but more frequently it is reduced to a membranous rim."

The lists of edible and poisonous fungi are relatively long, and while most belong to the Hymenomycetes, some are also yielded by the Gasteromycetes, as the puff-balls. The giant puff-ball (*Lycoperdon giganteum*) is found in the region of

San Francisco Bay, not rarely forty inches in diameter.

It is not possible in this limited space to even mention the various poisonous and edible fungi that experience has demonstrated are such. The number of species which have been eaten or experimented with, however, is small compared to the number of species recognized by botanists. Many students of fungi have formulated rules for distinguishing the edible from the poisonous fungi. "The different popular tests for distinguishing edible from poisonous fungi, such as, for instance, the blackening of a silver coin or spoon when placed in a mass of poisonous fungi while they are being cooked, are all absolutely worthless." The following rules, given by Prof. W. G. Farlow, should not be neglected by the beginner:

(1) Avoid fungi when in the button or unexpanded stage; also those in which the flesh has begun to decay, even if only slightly.

(2) Avoid all fungi which have stalks with a swollen base surrounded by a sac-like or scaly envelope, especially if the gills are white.

(3) Avoid fungi having a milky juice, unless the milk is reddish.

(4) Avoid fungi in which the cap, or pileus, is thin in proportion to the gills and in which the gills are nearly all of equal length, especially if the pileus is bright colored.

(5) Avoid all tube-bearing fungi in which the flesh changes color when cut or broken, or when the mouths of the tubes are reddish, and in the case of other tube-bearing fungi experiment with caution.

(6) Fungi which have a sort of spider-web or flocculent ring round the upper part of the stalk should in general be avoided.

Rules 1, 2, and 5 may, for the beginner, be regarded as absolute, with the exception to Rule 2, *Amanita cæsarea* (Scop.), Kaiserling, the gills of which are yellow. Rules 3, 4, and 6 have more numerous exceptions; but these rules should be followed in all cases, unless the collector is content to experiment first with very small quantities and learn the practical result.

The poisonous mushrooms are divided by R. Kobert (*Ueber Pilzvergiftung*, Dorpat, Nov. 1891) into four groups. The first group comprises those fungi which contain *muscarine* or some alkaloid allied to it. (See *Muscarine*, p. 1558.) In this group are included species of the old genus *Agaricus*, especially of the section *Ammonites*. In the second group are fungi containing a milky juice and having the generic name of *Lactarius* or *Galorrhœus*. Some of these species, such as *L. deliciosus*, are stated to be edible, but most of them have in their juice a violently irritant resin, which may produce severe, or even fatal, gastro-enteritis.

The third group contains species belonging to the genus *Helvella*, whose juice contains *helvellaic acid*, isolated by Boehm. It is asserted that these fungi, when thoroughly dried, are not poisonous, and that hot water also extracts from them the poisonous acid, so that boiling makes them edible. The chief physiological action of the acid seems to be to destroy the red blood-corpuscles, and, probably by such action, to produce vomiting, hæmoglobinuria, jaundice, irritation of the kidneys, etc.

The fourth and most important group of poisonous fungi is that which contains a large number of fungi which resemble edible species. According to the researches of Kobert, the toxic property of these fungi is a toxalbumin, which he has isolated from *Amanita phalloides* and given the name of *phallin*. Ordinarily, poisoning from mushrooms is due to plants of the present group. In many cases the fungi as eaten have tasted well, and no evil result has been apparent for many hours after their ingestion; in some cases for twenty hours. The symptoms have been great prostration and collapse, cold sweat, headache, stupor, amaurosis, delirium often with wild cries, coma, mydriasis, convulsions, marked cyanosis, and not rarely icterus; sometimes there is pronounced urticaria. There are usually distinct fever and rapid feeble pulse; whilst hæmoglobinuria, methæmoglobinuria, hæmaturia, albuminuria, and even suppression of urine have been noted. After death, post-mortem rigidity is often wanting, the gastro-intestinal tract is violently inflamed, the blood fluid and often escaping from the vessels and staining the tissues; whilst the liver, the heart, the diaphragm, and the muscles have been found in a state of fatty degeneration. The treatment of this form of poisoning consists in the immediate emptying of the alimentary canal by means of emetics, castor oil, and cathartics, and the meeting of symptoms as they arise.

B. W. Richardson, having noticed that the smoke of the *Lycoperdon proteus* or *puff-ball* was used for stupefying bees, found that the inhalation of the fumes caused various animals to become insensible. He had himself inhaled the fumes clarified by passing them through water, and experienced symptoms of intoxication and drowsiness. (*Lond. Med. Times and Gaz.*, 1853, 610.) Mr. Thornton Herapath, however, maintains, as the result of his experiments, that these anæsthetic effects are in reality not owing to any narcotic principle present in the fungus, but to the carbonic oxide gas generated during their combustion. (*Philosoph. Mag.*, July, 1855.)

MUSK, ARTIFICIAL. *Moschus Factitius.* The artificial musk introduced within recent years as a patented preparation, called "Musk Baur," from the name of the discoverer, Dr. A. Baur, is *trinitrobutyltoluene*, $C(CH_3)_3.C_6H(NO_2)_3CH_3$. It is prepared by adding tertiary butyltoluene slowly in the cold to five times its weight of a mixture of concentrated nitric and sulphuric acids, and afterwards heating the mixture for from eight to nine hours on a water-bath. It crystallizes from alcohol in yellowish-white needles, melts at from 96°–97° C., and is insoluble in water. It is, however, soluble in alcohol, ether, benzene, chloroform, and light petroleum ether.

Artificial musk is an antispasmodic and nervine, and possesses the general therapeutic properties of the natural substance, though in a weaker degree. Dose, ten grains (0·648 Gm.); for a child two years old, from half a grain to a grain (0·032–0·065 Gm.), every two or three hours. According to Berzelius, *tincture of artificial musk* is formed by dissolving a drachm of the musk in an ounce of alcohol, equivalent to ten fluidrachms, of the sp. gr. 0·835. Of this the dose for an adult is a teaspoonful. This tincture has been employed by Prof. Hauner, chief physician of the Children's Hospital at Munich, in uncomplicated *spasm* of the *glottis*, with invariable success in more than thirty cases.

MUTISIA VICIÆFOLIA. Cav. This composite is stated to be a valuable antispasmodic, useful

in hysteria and croup; it is also a cardiac tonic. (See *Newer Materia Medica.*)

MYDRINE. *Mydrin.* A colorless powder, composed of 100 parts of *ephedrine*, the active principle of a Japanese gentian, and 1 part of homatropine. It is easily soluble in water, is employed in 10 per cent. solution, and is said to be a useful evanescent mydriatic.

MYDROL. *Iodo-methyl-phenyl-pyrazolon.* A colorless, inodorous powder of bitter taste, easily soluble in water and alcohol. It is used as a mydriatic in 5 and 10 per cent. solutions.

MYRICA CERIFERA. L. *Wax-myrtle. Bayberry. Candle-berry. Arbre à suif*, Fr. *Wachsbaum, Wachsgagel*, G. This is an indigenous shrub, growing in great abundance in the sandy soil along the sea-shore, and even on the shores of our northern lakes. It belongs to the natural order Myricaceæ. The genus is characterized by its staminate flowers in cylindrical, and its pistillate in ovoidal closely imbricated catkins, without calyx or corolla, solitary under a scale-like bract with a pair of bractlets; the stamens from two to eight, with filaments somewhat united below; the ovary with three scales at its base, and two thread-like stigmas; the fruit a small spherical nut. The leaves of the wax-myrtle are oblong-lanceolate, narrower at their base, entire or somewhat toothed near the apex, shining, with resinous dots on both sides, and very fragrant when rubbed. The fruit is covered with a coating of white wax, and sometimes continues on the plant for two years or more. The shrub is from three or four to ten feet high, often thickly crowded, and, under such circumstances, scenting the air with its spicy odor. The coating of wax upon the surface is collected, and known in commerce as *myrtle wax.* (See *Vegetable Wax.*) A volatile oil might probably be collected by distillation from the leaves. The bark of the stem and root is supposed to possess valuable remedial properties, and has been employed to a considerable extent. In the dried state it is in quilled pieces of variable length, covered with a thin epidermis of a grayish color somewhat mottled, and marked with slight circular fissures. Within the epidermis the color is reddish brown. The bark is brittle, and of a peculiar, astringent, bitterish, and pungent taste, followed by a slight sense of acrimony. Its powder has a peculiar aromatic odor, and irritates the nostrils and throat when inhaled. It yields its virtues to water and alcohol. Geo. M. Hambright found in it volatile oil, starch, lignin, gum, albumen, extractive, a red coloring substance, tannic and gallic acids, an acrid resin soluble in alcohol and ether, an astringent resin soluble in alcohol and not in ether, and a peculiar acrid principle having acid properties. (*A. J. P.*, 1863, 193.) Moore (*Am. Journ. Sci.*, (2) 33, 113) found a large quantity of *palmitic* and a small quantity of *myristic acid*, for the most part in the free state, but to a smaller extent combined with glyceryl. The bark appears to be moderately tonic and astringent, and in large doses emetic. It has been considerably used by the "eclectics" in *diarrhœa, jaundice, scrofula*, etc. Externally the powdered bark is used as a stimulant to indolent *ulcers*, and the decoction as a gargle and injection in chronic inflammation of the throat, *leucorrhœa*, etc. Dose of the powder, twenty or thirty grains (1·3–1·9 Gm.), of a decoction (℥i to Oi), one or two fluidounces. An alcoholic extract, very inappropriately named *myricin*, is given in the medium dose of about five grains (0·32 Gm.). For analysis of the rhizome of *Myrica asplenifolia*, see *A. J P.*, 1892, 303.

MYROBALANS. *Myrobalani. Myrobalans*, Fr. *Myrobalanen*, G. Five varieties of these East India fruits are distinguished by authors. 1. *Myrobalani bellericæ.* These are obtained from *Terminalia bellerica*, Roxb. They are roundish or ovate, from the size of a hazel-nut to that of a walnut, of a grayish-brown color, smooth, marked with five longitudinal ribs, and sometimes furnished with a short, thick footstalk. They consist of an exterior, firm, resinous, brown, fleshy portion, and an interior kernel, which is light brown, inodorous, and of a bitterish very astringent taste. 2. *Myrobalani chebulæ.* This variety is produced by *Terminalia chebula*, Willd. (considered by some to be identical with *T. bellerica*, Roxb.). The fruit is oblong, pointed at each extremity, from fifteen to eighteen lines in length, of a dark brown color, smooth and shining, with five longitudinal wrinkles, but without footstalks. In their internal arrangement and their taste they resemble the preceding. 3. *Myrobalani citrinæ* vel *flavæ.* These are from a variety of the same tree which affords the last-mentioned myrobalans, from which they differ only in being somewhat smaller, of a light brown or yellowish color, and of a taste rather more bitter. They were formerly sometimes sold in the shops of Philadelphia, under the name of *white galls*, to which, however, they bear no other resemblance than in taste. 4. *Myrobalani indicæ* vel *nigræ.* These are thought to be the unripe fruit of *Terminalia chebula*, or *T. bellerica.* They are ovate-oblong, from four to eight lines long and from two to three lines thick, of a blackish color, wrinkled longitudinally, and presenting, when broken, a thick brown mass, without kernel, but with a small cavity in the centre. They are sourish and very astringent. 5. *Myrobalani emblicæ.* This variety is wholly different from the preceding, and derived from a plant having no affinity to the Terminaliæ, of the nat. ord. Combretaceæ,—namely, the *Phyllanthus emblica*, L. (nat. ord. Euphorbiaceæ). It is often in segments, as kept in the shops. When the fruit is entire, it is blackish, spherical depressed, of the size of a cherry, presenting six obtuse ribs with as many deep furrows, and separating into six valves, and has a strongly astringent and acidulous taste. These fruits were in high repute with the Arabians, and were long employed by European practitioners, as primarily laxative and secondarily astringent, in various complaints, particularly *diarrhœa* and *dysentery.* Their dose was from two drachms to an ounce. Pierre Apery states that when roasted they are still used in Turkey with excellent results in *intestinal catarrhs.* (*Rev. de Thérap.*, Dec. 1887.) We have been told that they have been used as a substitute for galls in the preparation of ink-powder. R. Hennig (*A. J. P.*, xlii. 318) found in them 45 per cent. of tannic acid, but this was relatively high, as they are ordinarily rated as containing from 20 to 40 per cent., *Terminalia chebula* yielding the most. Loewe considers the tannin of myrobalans to be identical with the *ellago-tannic acid.*

MYRONIN. An ointment vehicle introduced by R. Eggert, consisting of soap, carnauba wax, and *chenoceti* or *doegling oil.*

MYRRHOLIN. A patented solution made by digesting myrrh with castor oil and alcohol, and used as a vehicle for administering creosote in tuberculous diseases.

MYRTUS CHEKEN. Spreng. (Now *Eugenia Chequen*, Molina.) *Cheken, Chequen, Chekan.* (Nat. ord. Myrtaceæ.) The leaves of this Chilian plant have entered commerce under the name of *Chekan leaves*. Weiss (*P. J. Tr.*, 188, 246) has found in them,—1, *chekenon*, $C_{40}H_{44}O_8$, a crystalline body; 2, *chekenin*, $C_{12}H_{11}O_3$, in yellowish rhombic tables; 3, *chekenetin*, $C_{11}H_7O_6 + H_2O$, in olive-colored crystals; 4, *cheken-bitter*, an amorphous, very soluble bitter substance. (See also *P. J. Tr.*, 1889, 782.) Chekan leaves are reported by W. Murrell to be useful in chronic *bronchitis*. For an account of them and their properties, see *P. J. Tr.*, ix. 653; and *Newer Materia Medica*. Dose of fluid extract, from one to three fluidrachms (3·69–11·09 C.c.).

MYRTUS COMMUNIS. L. *Common European Myrtle.* (Nat. ord. Myrtaceæ.) The leaves of this plant yield, by distillation, *myrtol*, which is a mixture of a dextro-rotatory terpene, probably *pinene*, *cineol*, $C_{10}H_{18}O$, which is identical with cajuputol and eucalyptol, and another hydrocarbon. The mixture usually known as myrtol is collected between 160° and 180° C. Myrtol has recently been strongly recommended as an energetic antiseptic, which acts in full dose as a sedative to the nervous system, and is a powerful stimulant to the mucous membranes of the lungs and genito-urinary tract, through which channels it escapes into the system. It has been used to a considerable extent, with alleged excellent results, in the Paris Hospital, in the treatment of chronic *bronchitis* with or without dilated bronchi, asthma, or tubercle; and also in chronic *cystitis* or *pyelitis*. Herr Jahns believes that the medical activity of the oil depends upon the presence in it of *cineol*. Dose, from one to two grains (0·065–0·130 Gm.), given in capsules, from four to eight times a day. A de Vevey (*Revue de Thérap. Méd. Chirur.*, lxiii. 1896) has used this 10 per cent. solution in sterilized olive oil hypodermically (5–10 C.c.) once or twice in twenty-four hours, with asserted very good results in all forms of chronic or bronchial catarrh.

NABALUS ALBUS. (L.) Hook. *Prenanthes Alba*, L. *Rattlesnake Root. White Lettuce. Cancer Weed. Gall of the Earth. Lion's Foot.* In certain portions of Virginia and North Carolina, where this perennial herb grows, great value is attached to it in rattlesnake bite. The milky juice is taken freely internally, and its leaves steeped in water which is locally applied and frequently changed. The plant is also used in *dysentery*, and N. B. Williams has found tannin in the rhizome. (*A. J. P.*, 1887.)

NAG-KASSAR. For an account of this drug, which is composed of the anthers of an ornamental tree much cultivated in South Asia, see *Pharm. Post*, May, 1888.

NANCE BARK. This bark is believed to be obtained from the *Malpighia glabra*, L. (nat. ord. Malpighiaceæ); it is much used in Mexico for tanning, and, according to F. Holberg, contains 26·2 per cent. of tannin. (*A. J. P.*, xvi. 239.)

NAPHTALAN. This is a greenish-black soft mass, prepared by the fractional distillation of naphtha obtained from the Armenian highlands, having a slightly empyreumatic odor, a neutral reaction, and a specific gravity of 0·89. It melts at 70° C., is insoluble in water and glycerin, but mixes readily with fats and oils. It has recently been recommended as very efficacious in the treatment of *chronic eczema*, *sycosis*, and other parasitic skin affections, and as having a range of usefulness closely parallel to that of the oil of cade. It is necessary to apply it in the form of a thick coat to the affected skin and envelop it so as to exclude the air. Stains produced by it on the clothing can be removed by petroleum or benzole.

NAPHTHOL BISMUTH. *Beta-naphtol Bismuth. Orphol.* $(C_{10}H_7O)_3Bi + 3H_2O$. (Merck.) This is a neutral, light brown, almost odorless and tasteless non-irritant powder, insoluble in water, which, according to its manufacturer, contains 80 per cent. of bismuth in combination with 20 per cent. of beta-naphtol. According to the studies of M. F. A. Jasenski, it is broken up both in the stomach and in the intestines into its constituents, which are to a slight extent absorbed, but to a much greater extent excreted from the alimentary canal. If this statement be correct, it is evident that orphol must unite the local influence of beta-naphtol with that of bismuth, and it has been highly recommended by various clinicians as a gastro-intestinal antiseptic, useful in *acute* and *chronic enteritis*, in *fermentative diarrhœas*, in various forms of *dyspepsia*, and whenever an intestinal antiseptic is desired. It may also be used as a local remedy in *gonorrhœa* and various other *mucous inflammations*, and as an antiseptic application in external *ulcerations*, in *impetigo*, and in various other surgical disorders. The ordinary dose is from seven and a half to fifteen grains (0·5–0·9 Gm.) in capsule or suspended in water. It is affirmed, however, to be harmless, and Chaumier states that he has frequently given seventy-five grains a day to young children with impunity. It is probable that only a small portion of these large doses is decomposed in the gastro-intestinal tract, the greater part passing out unchanged.

NAPLES YELLOW. A yellow pigment prepared by calcining a mixture of lead, antimony sulphide, dried alum, and ammonium chloride, or a mixture of lead carbonate, diaphoretic antimony, dried alum, and ammonium chloride. (Gray.)

NARCISSUS PSEUDO-NARCISSUS. L. *Daffodil. Narcisse des prés Porillon*, Fr. *Gelbe Narcisse*, G. (Nat. ord. Amaryllidaceæ.) Both the bulb and the bright yellow flowers of this common garden plant have been used in medicine. The flowers have a feeble peculiar odor, and both have a bitter mucilaginous taste. They are an uncertain emetic. It is probable that the flowers of the wild European plant are more powerful than those of the cultivated. A. W. Gerrard examined the bulbs of daffodil, and obtained a crystalline neutral principle and an amorphous alkaloid, which he calls *pseudonarcissine*. The dose of the powder, to produce an emetic effect, varies, according to the statements of different physicians, from a scruple to two drachms; while the extract is said to vomit in the dose of two or three grains. The bulb is most powerful in the recent state. According to Ruiger, the alkaloid obtained by Gerrard from the bulb of the flowering plant dries the mouth, checks perspiration, dilates the pupil, especially when applied locally, quickens the pulse, and acts on the heart of the frog antagonistically to muscarine and pilocarpine, whilst the alkaloid taken from the bulb

after flowering causes salivation and perspiration, internally taken contracts the pupil, and topically applied dilates it slightly. (*Journ. of Physiol.*, i. 436.) In France, narcissus flowers have been used as an antispasmodic.

NARD. *Spikenard.* Several aromatic roots were known to the ancients under the name of *nardus*, distinguished, according to their origin or place of growth, by the names of *nardus Indica*, *nardus Celtica*, *nardus montana*, etc. They are supposed to have been derived from different species of Valeriana. Thus, the nardus Indica is referred to *V. Jatamensi* of Bengal, the nardus Celtica to *V. Celtica*, inhabiting the Alps, Apennines, etc., and the nardus montana to *V. tuberosa*, which grows in the mountains of the south of Europe. The Indian nard, or spikenard, sometimes also called Syrian nard, is still occasionally to be found in commerce. It is a small delicate root, from one to three inches long, beset with a tuft of soft, light brown, slender fibres, of an agreeable odor, and a bitter, aromatic taste. It was formerly very highly esteemed as a medicine, but is now almost out of use. Its properties are analogous to those of valerian.

NAREGAMIA, or GOANESE IPECACUANHA. The root of *Naregamia alata*, Wight and Arn. (nat. ord. Meliaceæ), of Western India, has been much employed as an emetic, as an hepatic stimulant in *dysentery*, and in small doses as an expectorant in *bronchitis*. Prof. Drasche, of Vienna, confirms the value of the drug. (*Centralb. Therap.*, 1890.) In it Hooper has found an alkaloid, *naregamine*, an oxidizable fixed oil, and a wax. (See *P. J. Tr.*, vol. xv., 1887.) The dose of a concentrated tincture (1 to 4) is from five to ten minims (0·3–0·6 C.c.); as an emetic, from fifteen to thirty minims (0·9–1·84 C.c.).

NASROL. $C_8H_9N_4O_2.SO_3Na$. *Sodium Sulpho-caffeate. Sodium Caffeine Sulphonate. Symphoral-sodium* is an intensely bitter powder recommended as a diuretic in *dropsy*. Dose, 1 grain (0·065 Gm.) given in capsules.

NASTURTIUM OFFICINALE. R. Brown. *Sisymbrium Nasturtium.* Linn. *Roripa Nasturtium.* (L.) Rusby. *Water-cress. Cresson de fontaine*, Fr. *Brunnen Kresse*, G. (Nat. ord. Cruciferæ.) In sensible and medical properties water-cress bears some resemblance to scurvy grass, though milder, and on this account is preferred for the table. It is thought to be useful in scorbutic affections and visceral obstructions. The expressed juice is sometimes given in the dose of one or two ounces; but the herb is more frequently used in the form of a salad. It contains a volatile oil, which, according to A. W. Hofmann, contains as its chief constituent a body boiling at 253° C., which he considers to be the nitrile of *phenyl-propionic acid*, $C_9H_{10}O_2$, and therefore has the formula $C_9H_{10}N$. Other species of Nasturtium, as *N. palustre* or *marsh water-cress*, and *N. amphibium* or *water-radish*, grow in similar situations with the *N. officinale*, and act similarly.

NEAT'S-FOOT OIL. *Oleum Bubulum. Oleum Pedum Tauri. Axungia Pedum Tauri. Huile (Graisse) des Pieds du gros Bétail*, Fr. *Klauenöl, Ochsen Klauenfett*, G. This formerly official oil is obtained by boiling for a long time the feet of the ox, previously deprived of their hoofs. The fat and oil which rise to the surface are removed, and introduced into a fresh portion of water, heated nearly to the boiling point. The impurities having subsided, the oil is drawn off, and, if required to be very pure, is again introduced into water, which is kept for twenty-four hours sufficiently warm to enable the fat which is mixed with the oil to separate from it. The liquid being then allowed to cool, the fat concretes, and the oil is removed and strained, or filtered through layers of small fragments of charcoal free from powder. The oil is clear and yellowish in color, of sp. gr. 0·916 at 15° C., and, when properly prepared, inodorous and of a bland taste. It thickens or congeals with great difficulty, and is, therefore, very useful for greasing machinery. It is also used for softening leather and grinding of metals. It has been given as a substitute for cod-liver oil in scrofulous diseases. It is apt to be laxative, and in certain cases proves useful in this way. It is given in the same dose as cod-liver oil. (See *Am. Journ. of Med. Sci.*, N. S., xxiv. 498.) It is at present difficult to obtain pure neat's-foot oil in commerce.

NECTANDRÆ CORTEX. *Br.* 1885. *Bebeeru Bark* is the dried bark of *Nectandra Rodiei*, Schomb. (Now *N. Rodiæi*, Hook.) (Nat. ord. Lauraceæ.) The *bebeeru*, *bibiru*, or *sipiri*, as it has been indifferently named, is a tree sixty feet or more in height, branching near the top, with a smooth, ash-gray bark. The leaves, which are five or six inches long by two or three in breadth, are nearly opposite, coriaceous, oblong-elliptical, shortly acuminate, smooth, shining, and obscurely reticulate on the upper surface. The flowers are yellowish white, in axillary panicles, much shorter than the leaves, and few-flowered. The fruit is a large, obovate or obcordate, somewhat compressed berry, of the size of a small apple, with a single seed about as large as a walnut. The tree inhabits Guiana and the neighboring regions of South America, where the wood is used in ship-building, under the name of *greenheart*. It received its specific name of *rodiei* from Sir Robert Schomburgk, in honor of Dr. Rodie, by whom it was first described. Though the fruit is very bitter, its seeds yield a starch which is said to be used as food by the Indians.

This is in large, flat, heavy pieces, from one to two feet long, from two to six inches broad, and three or four lines thick, with a rough and somewhat fibrous fracture, of a grayish-brown color on its outer surface and a dark cinnamon color on the inner. It has an intensely bitter, somewhat astringent taste. On microscopical examination it is seen to be composed chiefly of very thick-walled parenchymatous cells. The inner liber contains peculiar short, sharp-pointed, saw-shaped liber cells. Within the cells dark brown masses (colored greenish black by ferrous sulphate) may be seen. Analyzed by Dr. Maclagan, of Edinburgh, it was found to contain tannic acid of the kind that precipitates the salts of iron green, resin, gum, sugar, albumen, fibrin, various salts, and two peculiar alkaloids, named respectively *beberine*, $C_{18}H_{21}NO_3$, and *sipirine*, the former soluble and the latter insoluble in ether. In the seeds, besides the foregoing principles, Dr. Maclagan found 53 per cent. of starch, and a peculiar white, crystalline, volatile acid, which he named *beberic acid*. The alkaloids are extracted together from the bark, in the form of impure sulphates, by a process similar to that for preparing quinine sulphate. This prep-

aration is known as the *commercial beberine sulphate*. The official process of the Br. Pharmacopœia of 1885 also yielded an impure alkaloid. The alkaloid was obtained pure by Messrs. Maclagan and Tilley by the following process. The impure sulphate is dissolved in water and precipitated by ammonia. The precipitate, mixed with an equal weight of recently precipitated lead oxide, and dried, is treated with absolute alcohol, which, being evaporated, leaves the two alkaloids in the form of a translucent resinoid mass. The beberine is separated by means of ether, which yields it by evaporation. Another process is to dissolve the precipitate obtained by ammonia, previously washed, in diluted acetic acid, add lead acetate, precipitate by potassa, exhaust the precipitate by strong ether, evaporate the ether to the consistence of a syrup, dissolve the residue in absolute alcohol, and pour the solution gradually into water. A flocculent deposit is formed, which when washed and dried, is the alkaloid in question. Prof. Flückiger found the commercial article to yield a very trifling amount, less than 25 per cent., of the pure alkaloid. It is in dark brown translucent scales, yellow when reduced to powder, of a strongly bitter taste, and soluble in water and alcohol. According to Dr. Flückiger (*P. J. Tr.*, xi., 193, 1869), pure beberine is a white, amorphous powder, whose concentrated watery solution is not precipitated by tartar emetic, but affords abundant white precipitates with sodium phosphate, potassium nitrate, iodide, or iodohydrargyrate, mercury perchloride, potassium platino-cyanide, and nitric or iodic acid. Its acetate yields yellow amorphous precipitates with red or yellow potassium prussiate, potassium chromate, potassium bichromate, and platinum bichloride. Mr. D. B. Dott has confirmed the results of Prof. Flückiger's examination, although he found a larger percentage of alkaloids than the latter did. Owing to the difficulty of obtaining the alkaloids in crystals, it was almost impossible to ascertain the quantity present. (*Year-Book of Pharmacy*, 1881, 442; 1885, 420.) Beberine was asserted by Walz in 1860 to be identical with *buxine*, obtained from *Buxus sempervirens*. This statement was confirmed by Flückiger, who proved that *pelosine* was identical with both of the above principles. (*P. J. Tr.*, xi., 1870, 192.) The alkaloid dried at 100° C. has the formula $C_{18}H_{21}NO_3$. (Palen gives $C_{18}H_{21}NO_3$ as the formula.)

By treating the mixed alkaloids obtained from the wood with chloroform, Drs. Douglass Maclagan and Arthur Gamgee have separated an alkaloid, *nectandrine*. It is a white powder, amorphous, and intensely bitter. It differs from beberine in being much less soluble in ether, and, when treated with strong sulphuric acid and manganese dioxide, in giving rise to a magnificent green, slowly passing into a beautiful violet, and, lastly, in having a higher molecular weight, its formula being $C_{20}H_{23}NO_4$. After separating nectandrine from the mixed bases, the authors succeeded in extracting another alkaloid, different from beberine, much more soluble in water than nectandrine, but insoluble in chloroform. (*A. J. P.*, 1869, 453.)

Nectandra is tonic, somewhat astringent, and febrifuge, resembling cinchona in its virtues, though much inferior, at least in antiperiodic power. It has generally been employed in the form of the impure beberine sulphate, and sometimes with great asserted success, in the treatment of *intermittent* and *remittent fevers*. Dr. Rodie recommended it so early as 1834; but later experience shows that, though frequently successful, it often fails, and cannot be relied on as a substitute for quinine. From twenty grains to a drachm (1·3–3·9 Gm.) may be given between the paroxysms, in doses of two grains (0·13 Gm.). Beberine sulphate has been given in *dysmenorrhœa*, *menorrhagia*, and *leucorrhœa*, and in *blennorrhœal discharges*. The dose is from two to five grains (0·13–0·33 Gm.).

NERIUM ODORUM. Soland. *Nerium Oleander. Laurier Rose, Laurose*, Fr. *Oleander, Rosenlorbeer*, G. (Nat. ord. Apocynaceæ.) The common ornamental shrub known as *oleander* is affirmed to have been used from time immemorial in portions of Southern Europe for destroying rats, and a number of cases of poisoning by it have been reported. For collection, see *Therap. Gaz.*, July, 1888. The symptoms have been vomiting, abdominal pain with frequent cries, dilatation of the pupil, vertigo, convulsive movements, insensibility, small, very slow pulse, and in fatal cases epileptiform convulsions with coma ending in death. The action on the heart has in some cases in which death has not ensued been very pronounced, the pulse for five days remaining as low as forty per minute. The infusion made from four ounces of the root is affirmed to have taken life. M. E. Pelikan (*Compt.-Rend.*, 1866, 239) found that in the frog the extract of oleander causes immediate increase in the number of the heart-beats, followed after a little by slowing of the cardiac movements, and later by irregularity of contraction, ending in systolic arrest of the ventricles at a time when the auricles continue to beat and the frog is still able to jump about freely. Pelikan's experiments upon dogs have not, we believe, been published in detail, but they led him to the conclusion that the oleander acts in the mammal upon the heart in the same way as does digitalis. He also convinced himself that the active principle was a yellow, resinous principle, insoluble in water, easily soluble in amylic alcohol and chloroform, previously discovered by Latour. (*Journ. de Pharm.*, t. xxxii. 32.)

Two alkaloids have been discovered in oleander by Leukowsky (*Journ. de Pharm.*, (3) 46, 397), one named *pseudocurarine*, the other named *oleandrine*. Both neutralize acids; the former dissolves in water and alcohol, but not in ether, and is neither volatile nor poisonous; the latter is yellow, amorphous, very bitter, very slightly soluble in water, but more freely in alcohol and ether, and poisonous in its action on the system. H. G. Greenish isolated two substances, *neriodorin* and *neriodorein*, which are probably not pure proximate principles. (*A. J. P.*, 1881, 350.)

Schmiedeberg (*Archiv für Exper. Path. und Pharm.*, 1883, Bd. xvi. 145) finds two active substances in the oleander leaf. *Neriin* he believes to be identical with, or very closely allied to, digitalin. The second substance is *oleandrin*, previously described by Leukowsky as an alkaloid. Schmiedeberg shows that it is a glucoside, and on boiling with very dilute acids breaks up into sugar and a yellow resinous substance like digitaliresin. With concentrated acids it also decomposes, yielding an inactive resin. Schmiedeberg also obtained from African leaves a glucoside, *nerianthin*, which he surmises to be an educt from oleandrin. He

found oleandrin to be a powerful cardiac poison, but nerianthin not to have the power of arresting the frog's heart, although it exerts some influence upon it, possibly, as Schmiedeberg surmises, through contaminating oleandrin. Pieszczek obtained from oleander bark a principle which he named *rosaginin*, which was very poisonous, resembling strychnine in its action (*Archiv d. Pharm.*, ccxxviii. 352). Pouloux (*Bull. Thérap.*, May 15, 1888) finds that five centigrammes of the extract produced in the frog paralysis and death in about forty minutes; that the ventricle is thrown into a state of tetanus which is complete in about five minutes, the auricles continuing to contract for a considerable length of time. The mortal dose for the rabbit he determined to be about fifty centigrammes of the hydro-alcoholic extract. In a few cases of valvular *heart disease* Pouloux found oleander to do very well, and in seventy-five cases under the care of Freiherr (*Aerztliche Rundschau*, 1892) it acted promptly as a heart stimulant and tonic in cardiac weakness. Its diuretic action is said to be very marked, and not rarely it acts as a cathartic. Any irritation of the alimentary canal contraindicates its use. Under its influence the pulse rapidly becomes regular and slow, and dyspnœa and œdema disappear. Freiherr asserts that it is safer than digitalis in atheromatous diseases. He uses it in infusion or tincture, representing as the daily dose from three-quarters to one and a half grains (0·05–0·1 Gm.) of the dried oleander bark, one and a half to three grains (0·1–0·2 Gm.) of the fresh bark, one and a quarter to three and a half grains (0·08–0·25 Gm.) of the dried fruit. Pouloux's dose of the extract was three-quarters of a grain (0·05 Gm.). Orfele has used the dried flowers—dose, three grains (0·2 Gm.) in substance, or from ten to twenty drops of a 10 per cent. tincture—with success. The fluid extract would probably be the best preparation.

NEURODIN. *Acetyl-p-oxy-phenyl-urethane.* $C_6H_4(OCOCH_3)NH.COOC_2H_5$ Forms colorless, odorless crystals, fusing at 87° C., soluble in 1400 parts of cold water. It is used as an anodyne in neuralgia in doses of from fifteen to twenty grains (1–1·3 Gm.).

NICCOLIUM. *Nickel.* T. P. A. Stewart (*Archiv f. Exper. Path. und Pharm.*, Bd. xviii. 154) finds that in frogs soluble preparations of nickel produce palsy with convulsive movements which are due to an action upon the nerve-centres, the muscles remaining intact, the heart also being affected, as it is believed, by an action upon its motor ganglia. In mammals the chief symptoms produced by nickel are paralysis, with motor disturbance bearing some resemblance to chorea, with convulsions and great irritation of the gastro-intestinal tract, and a marked fall of the blood-pressure, due to paralysis of the vaso-motor centre. Large doses of nickel seem, however, to be necessary for a toxic influence, and the use of nickel in culinary instruments appears to be entirely safe. Riché (*Bull. Acad. Méd. de Paris*, 1888), as the result of experiments made upon dogs and guinea-pigs, reaches the conclusion that nickel is not more poisonous than iron. Thus, a dog absorbed over five drachms of it in sixty days, and increased in weight. The results obtained by Riché have been confirmed in Germany by Von Hamel Roos and by Schulz. (*P. J. Tr.*, Dec. 1887.)

Nickel Bromide is a greenish-yellow powder, of a sharp, almost burning taste, freely soluble in water, and making a grass-green solution. It is made by the action of bromine vapor upon the finely divided metal, either by heating the nickel in the vapor, or by the action of the two in the presence of water. It forms deliquescent needles of $NiBr_2+3H_2O$. It was first brought forward by J. M. Da Costa as a remedy for *epilepsy* and kindred disorders, and its value has been confirmed by R. Leaman. (*Med. Gazette*, April 18, 1885.) He affirms that ten grains of the nickel salt are equal to thirty grains of potassium bromide; that it is best used in effervescing form, made by mixing the salt with sodium bicarbonate and tartaric acid and moistening with alcohol and passing the moist powder through a sieve and drying in a warm closet. It has been physiologically investigated by H. A. Hare, who finds (*Therap. Gaz.*, vol. ii. 297) that it is a powerful paralyzant to the spinal cord, the motor and sensory nerve-trunks, and also to the voluntary muscle. In sufficient dose it causes immediate diastolic cardiac arrest. In smaller doses it lessens the arterial pressure by depressing the heart and the vaso-motor centres.

Nickel Sulphate, *Niccoli Sulphas*, $NiSO_47H_2O$, is formed by dissolving nickel carbonate in dilute sulphuric acid, concentrating the solution, and setting it aside to crystallize. The carbonate is procured by dissolving the impure nickel arsenide, sold under the name of *speiss*, coarsely powdered and mixed with half its weight of iron filings, in nitrohydrochloric acid. The solution is evaporated to dryness, and the residue treated with water, which takes up the impure nickel chloride, and leaves the arsenic in the form of the insoluble ferric arsenate. The liquid is then acidulated with hydrochloric acid, treated with hydrogen sulphide in excess, which precipitates the copper, and, after filtration, boiled with a little nitric acid to oxidize any remaining iron. The cold liquid, largely diluted with water, is next treated with a solution of sodium bicarbonate, gradually added, which throws down the iron in the state of ferric oxide. Lastly, the filtered solution, containing the nickel chloride nearly pure, is boiled with sodium carbonate, which, by double decomposition, throws down a pale green precipitate of nickel carbonate. Nickel sulphate is in the form of emerald-green crystals, efflorescent in the air, soluble in three parts of cold water, but insoluble in alcohol and ether. It has a sweet, astringent taste. Simpson, of Edinburgh, found this salt to act as a gentle tonic; useful in *migraine* in doses of from half a grain to a grain (0·03–0·06 Gm.) three times a day. In large doses it is liable to produce nausea and vomiting, especially when the stomach is empty. (See *Braithwaite's Retrospect*, xxvii. 446.)

Nickel-Carbonyl, *Carbonic Oxide of Nickel*, $Ni(CO)_4$, was first investigated by Mond, Lang, and Quincke, who reported to the Société de Biologie, 1890, that it is difficult to handle because its vapors produce excruciating headache, and that it is a violent poison, evidently destroying the hæmoglobin of the blood. Langlois (*Soc. de Biol.*, 1891), also McKendrick and Snodgrass (*Brit. Med. Journ.*, June, 1891), have repeated the experiments of the two investigators, and it would seem that the substance acts by being broken up in the body and yielding carbonic oxide to the hæmoglobin.

It produces prolonged fall of temperature, but it is not probable that it will prove of any practical value in medicine. For physical properties and methods of preparation, see authors already quoted.

NIGELLA SATIVA. L. *Nutmeg-flower. Small Fennel-flower. Faux Cumin*, Fr. *Schwarzkümmel*, G. (Nat. ord. Ranunculaceæ.) A small annual plant, growing wild in Syria and the south of Europe, and cultivated in various parts of the world. The seeds, *semen nigellæ*, are ovate, somewhat compressed, about a line long and half as broad, usually three-cornered, with two sides flat and one convex, black or brown externally, white and oleaginous within, of a strong, agreeable, aromatic odor, like that of nutmegs, and a spicy, pungent taste. (*P. J. Tr.*, 1882, 681.) Their chief constituents are a volatile and a fixed oil (1·5 per cent. of the former and 35 per cent. of the latter), and an amorphous glucoside, *melanthin*, which is decomposed by diluted hydrochloric acid into *melanthigenin* and sugar. The *nigellin* of Reinsch does not seem to have been a pure substance. Rochebrune has found a powerful paralyzing alkaloid, to which he gives the name of *nigelline*. (*Toxicol. Africaine*, vol. i.) Melanthin, according to W. Von Schulz, exhibits the typical physiological action of the most poisonous saponins. In India the seeds are considered as stimulant, diaphoretic, and emmenagogue, and are believed to increase the secretion of milk. They are also used as a condiment, and as a corrigent or adjuvant of purgative and tonic medicines.

NITRATED ALCOHOLS. The following substances of the possible series of nitrated alcohols have been studied by J. B. Bradbury (*British Med. Journ.*, ii. 1895):

Methyl Nitrate, $CH_3.ONO_2$ (CH_3NO_3).

Glycol (*Ethylene*) *Dinitrate*, $CH_2.ONO_2$ | $CH_2.ONO_2$ ($C_2H_4(NO_3)_2$).

Glycerol Trinitrate (*Nitroglycerin*), $CH_2.ONO_2$ | $CH.ONO_2$ | $CH_2.ONO_2$ ($C_3H_5(NO_3)_3$).

Erythrol Tetranitrate, $CH_2.ONO_2$ | $(CH.ONO_2)_2$ | $CH_2.ONO_2$ ($C_4H_6(NO_3)_4$).

(*Arabinol Pentanitrate*), $CH_2.ONO_2$ | $(CH.ONO_2)_3$ | $CH_2.ONO_2$ ($C_5H_7(NO_3)_5$).

Mannitol Hexanitrate, $CH_2.ONO_2$ | $(CH.ONO_2)_4$ | $CH_2.ONO_2$ ($C_6H_8(NO_3)_6$).

Of the group the first three are liquid. The others are crystalline colorless solids, stable in the dark at a moderately low temperature, turning yellow and giving forth nitrous fumes when exposed to the sunlight; exploding when heated rapidly or percussed. Of slight solubility in water, very soluble in alcohol and ether, responding when heated to the meta-phenylene diamine test.

Prof. Bradbury has shown that all these substances have similar physiological action, differing among themselves and from amyl nitrite simply in the rapidity and fugaciousness of influence. Glycol dinitrate in $\frac{1}{100}$ of a grain doses markedly influences arterial tension in the human being, but its effect is not maintained longer than sixteen minutes. Erythrol and mannitol nitrates were found to be slow in action but of remarkable permanence and influence, their effect on the lower animals lasting more than four or five hours. Methyl nitrate was feeble and fugacious in its influence.

Both erythrol and mannitol nitrates have been used by Prof. Bradbury in *angina*, *aneurism*, *Raynaud's disease*, *asthma*, *headache*, and various other affections for which nitroglycerin has been employed. Erythrol nitrate, as more soluble, appears to be preferable to mannitol nitrate; it has been used and highly commended by Arthur Burton and others. It may be given in powder or in solution. It is less easily exploded than nitroglycerin, but great care must be practised in any attempt at powdering, as a very serious explosion has occurred from rubbing it in a mortar with sugar of milk. One part of it may be dissolved in sixty parts of alcohol and a fluidrachm of this taken in an ounce of water every four to six hours. The dose of the 1 per cent. alcoholic solution of mannitol nitrate is one and a half fluidrachms. These solutions are said to be stable.

NITROBENZOL. *Nitrobenzene.* ($C_6H_5NO_2$.) Nitrobenzol is formed by the action of strong fuming nitric acid upon benzol, $C_6H_6 + HNO_3 = C_6H_5NO_2 + H_2O$. The product, after having been washed with water, is an oily, yellowish, intensely sweet liquid, with an odor like that of oil of bitter almond. Its density is 1·186, and boiling point 213° C. (415° F.). It has become of commercial importance, being produced as an intermediate product in the manufacture of aniline oil, and, under the name of *artificial oil of bitter almonds*, or *oil of mirbane*, being employed in confectionery, for scenting soaps, and for flavoring articles of diet. For method of detecting nitrobenzol in oil of bitter almond, see *Oleum Amygdalæ Amaræ*.

In manufactories where nitrobenzol is made, headaches, with sleepiness, are not infrequently produced by inhalation of the fumes; much more serious poisoning is liable to occur, and there have been a number of deaths produced by nitrobenzol. The symptoms may come on almost immediately, or they may be delayed for some hours. According to Filehne (*Arch. f. Exper. Path. und Pharm.*, Bd. ix.), the slowness of action is chiefly dependent on the fact that nitrobenzol, when mixed with the contents of the stomach and intestines, is absorbed with very great slowness; for if the drug be injected directly into the blood of the rabbit, it produces death in convulsions in less than a minute. The first symptoms of poisoning are headache, with muscular weakness, and a peculiar bluish color of the face, and disturbance of consciousness. In the fully developed poisoning the whole surface of the body is of a deep bluish color, and the mucous membranes a bluish gray; the pupils are dilated; the muscular relaxation is complete, except that sometimes the jaw is rigidly set; the consciousness is lost; the respiration is rapid, but shallow and irregular; the pulse rapid and thready, or entirely absent. The urine contains urobilin, indican, and acetone. Recovery may occur, as in a case reported by Stevenson (*Guy's Hosp. Rep.*, vol. xxi., 1876), after many hours of unconsciousness, the bluishness of the skin and the headache remaining for several hours longer. After death, the blood is of a deep chocolate brown, and, according to Filehne, has lost the power of absorbing oxygen. Lewin

has seen the blood so changed that, after five weeks' standing, the oxyhæmoglobin lines could still be made out; and its spectrum is altered. (See *Archiv für Physiologie*, 1879.)

In poisoning of the lower animals convulsions are frequent phenomena, and, according to Letheby, (*P. J. Tr.*, Sept, 1863), after small doses the animal sometimes for days will have more or less unconsciousness, with epileptic attacks, and at length die of exhaustion, or gradually recover. In the guinea-pig, but not in the dog, Ewald has found nitrobenzol to produce glycosuria. (*Phila. Med. Times*, vol. iv. 312.)

The cause of death appears to be paralysis of the central motor nervous centres. Letheby states that nitrobenzol is partly converted in the body into aniline, but this is denied by Filehne, who asserts that the aniline was produced by the processes used by Letheby. According to Caspar, death from prussic acid and nitrobenzol may be distinguished by the fact that when the body is left open for some hours, the odor of prussic acid leaves, while that of nitrobenzol persists. The minimum fatal dose is not known; according to Taylor, fifteen drops, taken by the mouth, have proved fatal, and in Stevenson's case, twenty-three minims (1·42 C.c.), taken in seven doses, in forty-eight hours, produced complete unconsciousness and the abolition of respiration, so that death would probably have occurred if treatment had not been instant.

The proper treatment would appear to be, emetics, the early use of artificial respiration, maintenance of the bodily temperature, and the stimulation of the circulation by hypodermic injection of atropine, strychnine, and digitalis, together with the administration of alcohol by the mouth. In a case reported by Dr. Werner (*Berlin. Klin. Wochensch.*, 1884, xxi.), life was apparently saved by bleeding sixteen fluidounces (473·2 C.c.) and transfusing twelve fluidounces (354·8 C.c.) of defibrinated blood.

Dinitrobenzol. Dinitrobenzene. $C_6H_4(NO_2)_2$. On boiling benzene with fuming nitric acid, there is formed chiefly metadinitrobenzene, fusing at 90° C., with small amounts of the ortho and para compounds. By crystallizing out of alcohol the meta compound can be obtained pure. Dinitrobenzol has attracted considerable attention on account of the number of cases of poisoning by it occurring among the workmen in alkaline manufactories. The symptoms are said to be jaundice, enlargement with tenderness of the liver, diarrhœa with colorless stools, and dark brown urine in which dinitrobenzol can be located by the phenyldiamin test. The toxicology has been especially studied by Strassmann and Strecker (*Friedreich's Blätt. f. Gerich. Med. u. Sanitätspolizei*, Heft iv., 1896), who add to the symptoms already given, headache, a peculiar bluish discoloration of the face and general surface, a tendency to fainting, with excessive sweating, vomiting, fall of temperature, great muscular weakness, and finally collapse. It is noted also that in animals experimentally poisoned there has been destruction of the red blood-corpuscles with consequent hæmoglobinuria and wide-spread fatty degeneration.

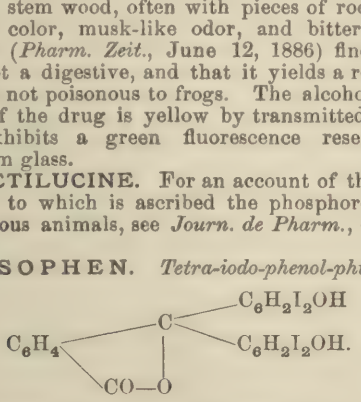
NITROGEN MONOXIDE, so-called *Nitrous Oxide. Laughing Gas. Oxyde nitreux, Protoxide d'Azote*, Fr. *Stickstoffoxydul, Lachgas*, G. N_2O. These names have been given to a gaseous substance, discovered by Priestley in 1776, but first brought into general notice in 1800 by Humphry Davy, who discovered and made known the remarkable exhilarating properties which earned for it the name of laughing gas.

Preparation. In its preparation, pure fused ammonium nitrate is submitted in a glass retort to a heat sufficient to decompose it, not exceeding 204·4° C. (400° F.); and the resulting gas and vapor are collected in a glass receiver over warm water or a saturated aqueous solution of common salt. Warm water is preferred because cold water absorbs much of the gas, and would consequently occasion loss; and even warm water, though it takes up much less, is not entirely unobjectionable on this score; and the saline solution is therefore probably, on the whole, best adapted to the purpose. When ammonium nitrate is heated to the point of decomposition, it is wholly resolved into aqueous vapor and nitrogen monoxide, according to the reaction: $NH_4,NO_3=(H_2O)_2+N_2O$. But it is necessary not to let the heat employed be too high, as otherwise, besides nitrous oxide, there will come over portions of nitric oxide, uncombined ammonia, and probably even nitric acid, which contaminate the product, and render it unfit for use. This may be avoided by arresting the process as soon as any white fumes appear in the retort. Peculiar care also must be taken that the ammonium nitrate should be pure, and especially free from ammonium chloride, which might cause an admixture of chlorine in the product. To insure against impurities of this kind, it is best in any case in the least doubtful, and perhaps it might be best in all cases, to cause the nitrous oxide, before it is used by inhalation, to pass successively through two solutions: one, of ferrous sulphate, to remove any nitric oxide that might be present; the second, of caustic potassa or soda, to neutralize acid impurities and chlorine. At times nitrogen gas is also found in the nitrogen monoxide, probably resulting from a trace of nitrite present or some reducing action upon the nitrate in the moment of its decomposition. When the monoxide is liquefied under pressure this free nitrogen remains as unliquefied gas.

Nitrogen monoxide gas is colorless, nearly or quite inodorous, slightly sweetish to the taste, and of the sp. gr. 1·527. Cold water will absorb about three-fourths of its bulk of the gas, and, under pressure, much more; and, thus impregnated, has a slight, not unpleasant smell, and a sweetish taste. By the joint influence of cold and pressure the gas may be condensed into a liquid, which is colorless, very mobile, and capable, under the ordinary atmospheric pressure, of remaining liquid at —12·7° C. (9° F.). The liquefaction was effected by M. Bianchi at 0° C. (32° F.), under a pressure of thirty atmospheres. (*A. J. P.*, 1865, 275.) Inflammable bodies will generally burn with increased vigor in nitrous oxide, which is, however, entirely incapable of giving oxygen to the blood. It consists of two atoms of nitrogen and one of oxygen, and its formula is N_2O.

The anæsthetic property of nitrogen monoxide was discovered by Humphry Davy, who even suggested that it might be used to prevent pain in surgical operations; but the first practical application of it to this purpose was made by the late Horace Wells, of Connecticut. The measure, however, so promising at the outset, was entirely neglected. No further attention was given to the subject for

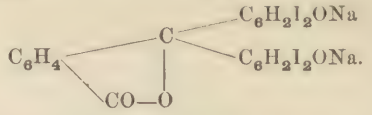
sixteen or more years, when G. L. Colton introduced the use of the gas as a practical anæsthetic in dentistry. It is distinguished among remedies of its class for the rapidity and brevity of its action.



For short minor surgical operations the gas is an excellent anæsthetic, but in severe operations it is not to be relied on, any interruption of the inhalation being followed by immediate return to consciousness. The apparatus required for its production, storage, exhibition, and administration is also so cumbrous that practically nitrous oxide is only employed by the dentist. It is certainly a very safe agent when used with due care, although it has caused death. The common mode of exhibition is by means of an air-tight bladder or bag, with a tube and mouth-piece attached.

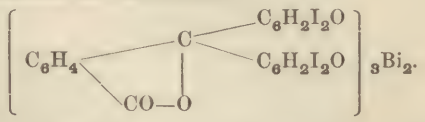
Nitrous Oxide Water Water, impregnated by pressure with about five times its volume of nitrogen monoxide, forms the *nitrous oxide water*, known in England under the name of *Searle's patent oxygenous aërated water*, which has been used to some extent as an internal remedy. Humphry Davy tried the aqueous solution, made without pressure, and thought it acted as a diuretic and promoted digestion; and Sérullas used it in cholera with apparent advantage. George J. Ziegler asserts that water charged with five times its volume of the gas possesses tonic, resolvent, exhilarant, and diuretic properties. He has observed, however, that its free and prolonged use is apt to produce emaciation.

NJIMO WOOD. *Njimo* was introduced into Germany from the Cameroons with the statement that it had digestive properties similar to pepsin. It is a stem wood, often with pieces of root, of a yellow color, musk-like odor, and bitter taste. Schulz (*Pharm. Zeit.*, June 12, 1886) finds that it is not a digestive, and that it yields a resinous extract not poisonous to frogs. The alcoholic extract of the drug is yellow by transmitted light, but exhibits a green fluorescence resembling uranium glass.



NOCTILUCINE. For an account of this substance, to which is ascribed the phosphorescence of various animals, see *Journ. de Pharm.*, 4e sér., xvii.

NOSOPHEN. *Tetra-iodo-phenol-phthalein.*



Nosophen is obtained by the action of iodine on solutions of phenolphthalein. It is an impalpable, yellowish-gray, odorless, tasteless powder, containing 61·7 per cent. of iodine in combination. It may be heated up to 220° C. without decomposition. It is insoluble in water and acids, soluble with difficulty in alcohol, glacial acetic acid, ether, and chloroform, but readily soluble in alkalies, with the last of which it forms salts from which it is easily freed at low temperature by carbonic acid. In the presence of heat it drives carbonic acid from its alkaline salts. By virtue of its two hydroxyl groups, nosophen is an acid, readily soluble in alkalies with replacement of the hydrogen atoms of both hydroxyl groups by a metal. Two salts of it have been put upon the market,—the sodium salt (antinosine) and the bismuth salt (eudoxine).

Antinosine has the following structural formula:

It is a dark blue, amorphous powder which is readily soluble in water and alcohol.

Eudoxine has the formula

It is a reddish-yellow, tasteless, odorless powder, insoluble in water, which is decomposed by alkalies into bismuth oxide and the soluble soda salt of tetra-iodo-phenol-phthalein. It contains 52·9 per cent. of iodine and 14·5 per cent. of bismuth.

Medical Properties and Uses. It is stated that in nosophen and its two salts the iodine is so firmly combined that it is not liberated in the human system, either when applied locally or administered internally, and that the preparations are therefore incapable of producing toxic effects. It is further affirmed that nosophen is in itself germicidal and locally an alterative, and that, being free from toxic properties, it is superior to iodoform. It is not irritant, and may be used freely as a local application in powdered form in all those cases to which iodoform is applicable, and has been especially recommended in nasal and laryngeal diseases. It has been administered internally as an intestinal antiseptic in doses of from five to eight grains (0·3–0·5 Gm.).

It is affirmed that antinosine has the same general properties as a germicide as nosophen, and that being soluble in water it affords a valuable application in many cases to which the nosophen as a dusting powder is scarcely applicable. The strength of the local application varies: from 2 to 3 per cent. in diseases of the nose, mouth, and throat, from 1 to 2 per cent. in *gonorrhœa*, from ½ to 1 per cent. for irrigation of the bladder and in *cystitis*, from 1 to 500 to 1 to 1000 for washing out of the stomach in *gastric catarrh*, *cancer*, etc.

Its 2 per cent. solution is said by W. F. Coleman to act most favorably in all forms of external inflammation about the eye, in purulent *otitis media*, etc. Owing to its solubility in water and its freedom from odor and taste, it is coming into vogue as a mouth-wash; for this purpose its glycerin solution is preferable, aromatics being added to taste. 5 C.c of the 1 per cent. solution in a tumblerful of water is the strength commonly employed, but when there is a severe *stomatitis* a 2 per cent. or even stronger solution may be used without dilution.

Its intravenous use has been suggested, but, according to Binz and Zantz (*Fortschritte d. Med.*, xiii., 1895), it is decomposed in the blood when so given and nosophen precipitated.

Eudoxine is believed to be slowly decomposed by the alkaline juices of the intestines, with liberation of antinosine and bismuth. It has been given in doses of from a half to eight grains (0·03–0·5 Gm.) three times a day, with alleged most excellent results, in *diarrhœas*, *gastric* and *intestinal indigestions*, and even *gastric cancer*.

NUCLEIN is a compound proteid closely resembling mucin, but distinguished by its phosphorus content (1·89–2·88 per cent.), while it contains no sulphur. It is probable that numerous varieties of nuclein exist, all being compounds of simple proteids with nucleic acid. Nuclein may be isolated by treating the cells with artificial gastric juice, by which the investing protoplasm is dissolved, leaving the nuclein unaffected. Nucleic acid is an amorphous white powder of strong acid reaction, readily soluble in water containing a small amount of alkali, insoluble in alcohol and ether.

The nuclein solution is a 5 per cent. solution of nucleic acid from yeast in water. It is at present probable that nucleic acid, when given internally, enters the circulation and circulates unchanged. It has been asserted that it has an extraordinary power in improving the general nutrition and increasing the resistive power of the system to pathogenetic germs, and is therefore a very valuable remedy in *tuberculosis*, in *anæmia*, in *general debility*, in *neurasthenia*, and even in acute germ diseases, such as *diphtheria*. It appears to be non-toxic, since Vaughan and McClintock have injected it into the blood of animals in such amount that the entire blood contained $1\frac{8}{10}$ per cent. of pure nucleic acid; and it is probable that the good results which have occasionally followed its use in practical medicine have been accidental, or due to a psychical influence rather than any remedial power of the remedy. The assertion frequently made that nucleic acid is the substance to which the human body owes its resistive power to morbific organisms is unproved and highly improbable. Its hypodermic injection produces so much pain that patients will rarely tolerate it. According to its manufacturers, the 5 per cent. solution may be given in doses of one drachm (3·9 Gm.) three times a day.

NUPHAR. The seed of *Nuphar luteum*, Sibth and Sm. (nat. ord. Nymphæaceæ), according to W. Grüning, contains *nuphar-tannic acid*, $C_{56}H_{56}O_{37}$, in considerable quantity. (*A. J. P.*, 1883, 96.)

NYMPHÆA ODORATA. Dryand. (Now *Castalia Odorata* (Dryand), Woodv. and Wood.) *Sweet-scented Water-lily.* The root of this well-known American plant is very astringent and bitter, and, according to Bigelow, contains much tannin and gallic acid. The root of the *Nymphæa alba*, or European *white water-lily*, was esteemed antaphrodisiac by the ancients. The tannic acid contained in this root has been named *nymphæ-tannic acid*, and the formula $C_{56}H_{58}O_{38}$ given it. (*A. J. P.*, 1883, 96.)

NYSSA GRANDIDENTATA. Michx. f. (Now *N. uniflora*, Wangenhr.) *Tupelo Gum. Sour Gum. Ogeechee Lime.* (Nat. ord. Cornaceæ.) *Tupelo root* has been recommended for surgical tents, because it expands more rapidly than sponge or laminaria. (*A. J. P.*, 1883.)

OATMEAL. *Avenæ Farina. Farine d'Avoine*, Fr. *Hafermehl*, G. *Farina dell' Avena*, It. *Harina de Avena*, Sp. *Avena sativa*, L., or the common oat, is so well known that a minute description would be superfluous. It is specifically distinguished by its "loose panicle, its two-seeded glumes, and its smooth seeds, one of which is awned." It was known to the ancients, and is now cultivated in all civilized countries; but its original locality has not been satisfactorily ascertained. It grows wild in Sicily, and is said to have been seen by Anson in the island of Juan Fernandez, off the coast of Chili. The seeds deprived of their husks are sometimes known as *groats*. As a human food coarsely ground oatmeal is usually preferred to the fine meal, and the grain grown in a northern climate is superior to that produced farther south. Hence Canada and Irish and Scotch oatmeals are better than the meals produced in the middle of the United States, the product of which country is chiefly consumed by horses. Diuretic properties have been attributed to the oatmeal, but probably incorrectly. *Tinctura Avenæ Sativæ* may be made by percolating 4 troy-ounces of the ground oatmeal with 1 pint of diluted alcohol, reserving the first $5\frac{1}{2}$ fluidounces, and evaporating the remainder down to half a fluidounce and adding to the reserved portion. (H. E. Heinitsh, *A. J. P.*, 1886, 86.)

Oatmeal contains, according to Vogel, in 100 parts, 59 of starch, 4·30 of a grayish substance, resembling coagulated albumen rather than gluten, 8·25 of sugar and a bitter principle, 2·50 of gum, 2 of fixed oil, and 23·95 of fibrous matter, including loss. A very elaborate report on the composition of American cereals by Clifford Richardson (*Department of Agriculture*, Bulletin No. 9, 1886) gives as the average ratio in oats from all parts of the country 70 per cent. of kernel to 30 per cent. of husk. According to the same authority, the composition of the kernel (average of 179 analyses) is as follows: water, 6·93 per cent.; ash, 2·15; oil, 8·14; carbohydrates, 67·09; fibre, 1·38; albuminoids, 14·31; corresponding to nitrogen per cent. 2·28. The nitrogenous principle has been called *avenin*, and resembles legumin somewhat. Ritthausen (*Die Eiweisskörper*, Bonn, 1872, 135) considers Nortin's avenin to have been a mixture of legumin or vegetable casein and a vegetable gluten containing sulphur, to which he gives the name *gliadin*, the legumin, however, predominating.

Gruel made with fine oatmeal affords a nutritious, bland aliment, which, from its somewhat laxative tendency, is often preferable to other amylaceous preparations. *Oatmeal gruel* may be prepared by boiling an ounce of the meal with three pints of water to a quart, straining the decoction, allowing it to stand till it cools, and then pouring off the clear liquor from the sediment. Sugar, lemon-juice, or wine may be added to improve its flavor.

OCHRES. These are native mixtures of argillaceous or calcareous earth and iron and manganese oxides, employed in painting. They are prepared for use by agitating them with water, decanting the turbid liquor after the coarser particles have subsided, then allowing it to rest in order that the finer parts may be deposited, and, lastly, drying the sediment which forms. The color of the ochres varies with the state of oxidation of the iron, and with the proportion which the iron bears to the other ingredients, and is sometimes artificially modified by the agency of heat. Several varieties are known in commerce under different names, according to their color or place of origin. Such are the *brown ochre*, the *yellow ochre*, the *red ochre*, the *Roman ochre*, of a brownish-yellow changing by heat to a purple-red, the *Oxford ochre*, of a brownish-yellow color less deep than the Roman, and the *French ochre*, which is yellow. The *Indian red*, from the Persian Gulf, and the *Spanish brown* and *Venetian red* may also be ranked in this class of pigments. Sometimes ochres come in powder,

and sometimes in hard masses known as *stone ochres*.

OCIMUM BASILICUM. L. *Basil. Sweet Basil. Grand Basilic*, Fr. *Basilien Kraut*, G. (Nat. ord. Labiatæ.) An annual plant, a native of India and Persia, and cultivated in Europe and in this country in gardens. The whole plant has a strong, peculiar, agreeable, aromatic odor, which is improved by drying. The taste is aromatic, and somewhat cooling and saline. It yields by distillation a yellowish-green volatile oil, lighter than water, which on being kept solidifies into a crystalline camphor, isomeric with turpentine-camphor. (*Gmelin's Handbook*, xiv. 359.) Basil has the ordinary properties of the aromatic plants, and is used as a condiment. The seeds are said by Ainslie to be used in India in *gonorrhœa*.

ODONTODOL. This is said to be a mixture of one part each of cocaine hydrochlorate and oil of cherry laurel, 10 parts of tincture of arnica, and 20 parts of solution of ammonium acetate.

ŒNANTHE CROCATA. L. *Hemlock. Water-dropwort. Dead-tongue.* A perennial, umbelliferous, aquatic European plant, exceedingly poisonous both to man and inferior animals. The root, which has a sweetish not unpleasant taste, is sometimes eaten by mistake for other roots, often with fatal results. The symptoms produced are those of irritation of the stomach, besides failure of circulation, and great cerebral disturbance, indicated by giddiness, convulsions, and coma. (See *P. J. Tr.*, 1874, 202.) Externally applied, the root produces redness and irritation of the skin, with an eruption. It is said to be sometimes used empirically as a local remedy in *piles*. Other species of *Œnanthe* are poisonous, and the whole genus should be suspected. We have two or three indigenous species. In cases of poisoning, the stomach should be at once evacuated, and symptoms met as they arise. A peculiar resinoid principle, denominated *œnanthin*, has been found by Gerding in *Œnanthe fistulosa*, of which half a grain (0·03 Gm.), given to an adult, produced long-continued irritation of the fauces, and a grain (0·06 Gm.) occasional vomiting. (See *A. J. P.*, xxi. 68.) In the *P. J. Tr.*, vol. xvi. 357, is a paper upon the recognition of *Œ. crocata* in cases of suspected cattle-poisoning.

ŒNANTHE PHELLANDRIUM. Lam. *Phellandrium aquaticum.* Linn. *Fine-leaved Water-hemlock. Fructus Phellandrii*, P. G. *Wasserfenchel*, G. *Phellandrie, Fenouil d'Eau*, Fr. A biennial or perennial, umbelliferous, European water-plant, the fresh leaves of which are said to be injurious to cattle, producing a kind of paralysis when eaten. By drying, they lose their deleterious properties. The *seeds* are from a line to a line and a half in length, ovate-oblong, narrow above, somewhat compressed, marked with ten delicate ribs, and crowned with the remains of the calyx, and with the erect or reverted styles. Their color is yellowish brown; their odor peculiar, strong, and disagreeable; their taste acrid and aromatic. Among their constituents is a volatile oil, upon which their aromatic flavor depends. By C. Fronefield it has been rendered probable that they contain a volatile alkaloid, analogous to coniine, if it be not *coniine* itself; for if the powdered seeds are rubbed with solution of potassa, the peculiar mouse-like odor of that alkaloid is exhaled. The powder was submitted to distillation with caustic potassa, the alkaline liquid obtained was neutralized with sulphuric acid and evaporated to a syrupy consistence, alcohol was added to precipitate the ammonium sulphate, the liquid was then filtered, treated with caustic potassa, and again distilled. On the surface of the distillate a yellow oily fluid floated, which was only slightly soluble in water but readily so in ether and alcohol, evinced an alkaline reaction with turmeric paper, and neutralized the acids. (*A. J. P.*, May, 1860, 211.) In overdoses the seeds produce vertigo, intoxication, and other narcotic effects. They have been used in chronic pectoral affections, such as *bronchitis, pulmonary consumption*, and *asthma;* also in *dyspepsia, intermittent fever*, obstinate *ulcers*, etc. The dose of the seeds, to commence with, is five or six grains (0·324 or 0·389 Gm.), so repeated as to amount to a drachm in twenty-four hours. They should be given in powder. Dose of alcoholic extract, three grains (0·194 Gm.). (*P. J. Tr.*, xii. 591.) A resinous principle, *œnanthotoxin*, $C_{17}H_{22}O_5$, has been extracted from *O. crocata*, which is reputed to be very poisonous.

ŒNOTHERA BIENNIS. L. *Tree Primrose. Evening Primrose. Onagre*, Fr. *Nachtkerze*, G. (Nat. ord. Onagraceæ.) The fleshy root of this plant, before the introduction of the potato, was used as a table vegetable. Many years ago R. E. Griffith commended very highly a strong decoction of the plant frequently applied in eruptive skin diseases. More recently the drug has been commended in *whooping-cough* and spasmodic *asthma*, and the ointment has been used in *porrigo* and other cutaneous affections of infants, and as an application to *ulcers*. Dose of fluid extract, from a half to one fluidrachm (1·8–3·6 C.c.). The ointment may be made by incorporating four ounces of the fluid extract in a pound of vaseline or lard.

ŒSYPUS. A cheap, crude wool fat obtained as a by-product in cleansing sheep-wool. (See *Adeps Lanæ Hydrosus.*)

OIL OF ANDA. A fixed oil procured by expression from the seeds of *Anda* (now *Joannesia*) *brasiliensis* (Raddi), *Anda* (now *Joannesia*) *Gomesii* (Ad. Jussieu), *Joannesia princeps* (Vell) (nat. ord. Euphorbiaceæ). The bark of *J. princeps* (Vell, of Brazil) yields on being wounded a milky juice, which is said to be poisonous, and to be used for stupefying fish. The fruit, which is about as large as an apple, ash-colored, with two larger and two smaller angles, encloses a two-celled nut, containing two seeds, about the size of a chestnut. Like the seeds of other euphorbiaceous plants, these are actively purgative; one seed, according to Martius, being the dose for a man. By expression these seeds yield a pale yellow, transparent oil, with little smell or taste, which is said to be used in Brazil for burning and painting. It has a sp. gr. 0·927, and in properties belongs to the class of semi-drying oils. Mello Olliveira has found in it an alkaloid, *joannesine*, which Couty affirms to be inert. (*N. R.*, 1881, 260.) Norris, who tried the oil at the Pennsylvania Hospital, found it to operate on the bowels moderately in the dose of fifty drops, and copiously when more largely given. Manoel de Castro and other Brazilian physicians assert that in doses of from one to two teaspoonfuls it acts in a manner very similar to castor oil, over which it has the great advantage of not being nauseous to the taste.

OIL OF BEN. This is a fixed oil extracted from the seeds of the *Moringa pterygosperma*,

Gaertn. (*Hyperanthera Moringa*, Vahl.), and *M. aptera* of Gaertner, and not to be confounded with oil of benne from *Sesamum indicum*, L. (nat. ord. Pedaliaceæ). These are trees of the nat. ord. Moringaceæ, inhabiting different parts of India, Arabia, Syria, etc., and introduced into the West Indies. James Macfadyen, in his *Flora of Jamaica* (i. 325), states that it is not the *M. pterygosperma* which yields the commercial oil of ben, but the *M. aptera*, which has not been introduced into Jamaica. He says, however, that an excellent and palatable oil may be obtained by expression from the seeds of *M. pterygosperma*, growing in that island. The leaves and other parts have an acrid property, which has probably given the name of *horseradish-tree* to *M. pterygosperma*. According to Henry Shachan (*Nouv. Remèdes*, 1890), the tincture of the root is very actively diuretic and useful in cardiac dropsy. The oil of the seeds has long been known, though used in the arts rather than in medicine. It is prepared in Europe from the seeds brought from Egypt; and it would appear, from the statements of Macfadyen, that the idea generally prevailing that it is also extracted in the West Indies is incorrect. The oil has a sp. gr. of from 0·912 to 0·917; it solidifies at about 0° C.; indeed at 7° C. it begins to deposit the solid fats. It is inodorous, clear, and nearly colorless, and keeps long without becoming rancid. It resembles olive oil, and is used for similar purposes. Mérat and De Lens say that it is purgative; but most of the fixed oils are so in sufficient doses. According to Völcker, the oil contains palmitin, olein, and a peculiar fatty matter yielding an acid by saponification, which he names *benic* (or *behenic*) *acid*. (*Journ. de Pharm.*, xvi. 77.) Heintz considers benic acid as simply a mixture of palmitic and myristic acids. (*Pogg. Ann.*, xcii. 601.) It is, however, now recognized as one of the normal fatty acid series, possessing the formula $C_{22}H_{44}O_2$.

OIL OF CITRONELLA. *Oleum Andropogon Nardi.* This oil is distilled from the *Andropogon Nardus*, L. (nat. ord. Gramineæ), a plant growing sometimes to the height of five or six feet, which is cultivated in Ceylon and in the Straits Settlements, and also on the Malabar coast. According to the statements of Consul Freudenberg, this oil is produced largely in the southern provinces of Ceylon by natives, either by distillation with steam or with a naked fire. The production has greatly increased; in 1864, 622,000 ounces were exported from Ceylon; in 1886, the quantity rose to 6,461,278 ounces; in 1898, the exports from Colombo and Galle reached the highest figure,—viz., 21,854,672 ounces, of which 11,149,704 ounces went to England and 9,903,984 ounces to America. For a method of production, see *Western Druggist*, 1888, 243. Oil of citronella is of a yellowish-green color, having a characteristic odor and pungent taste. Its sp. gr. is, according to Kremer, 0·8833. It mixes with alcohol in all proportions, and the test for purity given by Schimmel & Co. is based upon its behavior towards alcohol of 75 per cent.: "one volume of the oil must form an absolutely clear solution with *two* or at most *two and a half*, volumes of 75 per cent. alcohol at a temperature not below 20° C. (68° F.). A cloudy mixture indicates the presence of turpentine, certain fixed oils, and other essential oils which are sometimes used to adulterate it." The oil contains, according to *Schimmel & Co.'s Report*, April, 1897, *camphene*, *dipentene*, *methyl heptenone*, *citronellal*, *borneol*, and *geraniol*. Oil of citronella is an aromatic not used in medicine, but largely employed in perfuming so-called *honey soap*.

OIL OF EUPHORBIA. A fixed oil, obtained from the seeds of *Euphorbia Lathyris*, L. (nat. ord. Euphorbiaceæ), a biennial plant growing wild in this country, though believed to have been introduced from Europe. It is often found near gardens and in cultivated fields, and is generally called *mole plant*, under the impression that moles avoid the ground where it grows. (Pursh.) It is the *caper plant* of England. Like the other species of Euphorbiaceæ, it contains a milky juice, which is extremely acrid; and the whole plant possesses the properties of a drastic purge; but the oil of the seeds is the only part used in medicine. This may be extracted by expression, or by the agency of alcohol or ether. In the first case, the bruised seeds are pressed in a canvas or linen bag, and the oil which escapes is purified by decanting it from the whitish flocculent matter which it deposits upon standing, and by subsequent filtration. By the other process, the bruised seeds are digested in alcohol, or macerated in ether, and the oil is obtained by filtering and evaporating the solution. According to Soubeiran, however, the oils obtained by these different processes are not identical. That procured by expression is probably the purest.

Oil of euphorbia is colorless, inodorous, and, when recent, nearly insipid; but it speedily becomes rancid, and acquires a dangerous acrimony. Soubeiran has ascertained that it has a complex composition, containing, besides the pure oil, four distinct proximate principles. (*Journ. de Pharm.*, xxi. 259.) From 40 to 44 parts are obtained by expression from 100 of the seed. It is a powerful purge, but in doses of from five to ten drops is stated by Continental physicians to act kindly upon the bowels. In this country, however, it has been found very uncertain in its effects, and very liable to vomit. (*Journ. Phil. Col. Pharm.*, iv. 124.)

OIL OF JASMINE. This oil is obtained from the flowers of *Jasminum officinale*, L., or *common white jasmine*, of *J. sambac*, Solander, and of *J. grandiflorum*, L. Alternate layers of the fresh flowers, and of cotton saturated with the oil of ben or other fixed oil, are exposed in a covered vessel to the warmth of the sun; the flowers being renewed till the oil becomes impregnated, when it is separated from the cotton by pressure. This method is necessary, as the flowers do not yield their aroma by distillation. The oil is used only as a perfume. W. H. Hall records (*Med. and Surg. Rep.*, Jan. 1861) the case of a child poisoned by the fruit of a jasmine, probably the common white species. The symptoms were coma, widely dilated pupil, and snoring respiration, with a cold pale surface, and slow and feeble pulse, followed by violent convulsions, with rigidity of the muscles about the head and throat.

OIL OF LEMON-GRASS. *Oleum Andropogon Citrati.* This oil is distilled from *A. citratus*, D. C., and probably other grasses of the genus *Andropogon*, as *A. iwarancusa*, *A. calamus*, *A. martini*. *Andropogon citratus* is a large, coarse-looking grass, cultivated largely in India, the Malay Peninsula, Ceylon, and the neighborhood of Singapore. It grows in light soil, requiring very little care in cultivating, but considerable

moisture. The oil, which is frequently called *oil of verbena*, is mentioned by Roxburgh as being distilled in the Moluccas as early as 1820. It is exported in large quantities from Ceylon, India, and adjacent countries. It is a yellowish-brown liquid having a characteristic odor and a pungent taste. Like oil of citronella, it yields a crystalline solid when treated with sodium bisulphite. It is sometimes used in Eastern countries as a carminative and stimulant. Its sole use in this country is in perfumery.

OIL OF MAIZE. Our American maize or Indian corn yields a bright golden-yellow oil, of peculiar pleasant odor and taste. It is moderately thick, and has a sp. gr. at 15° C. of 0·916. It consists of olein, stearin, and palmitin, and solidifies at —10° C. The oil is contained in the germs of the seed alone. Reckoned on the whole weight of the seeds the oil constitutes 11 per cent., of which from 6 to 8 per cent. is extracted; reckoned on the weight of the germ itself, after separation from the starchy body of the seed, the oil amounts to 22 per cent. It is now being extensively produced in the Western United States in connection with the working of starch and glucose factories.

OIL OF MEXICAN LIGNALOES. This volatile oil, which is used chiefly on account of its fragrant odor (which has been described as resembling that of a mixture of lemon and jasmine), is said to be obtained by the distillation of the wood of undetermined species. J. Möller has published a series of articles upon the anatomical structure of commercial aloe wood in *Pharm. Post*, 1898. For description, and also the chemical characteristics of the oil, see *P. J. Tr.*, Aug. 1887,

OIL OF PATCHOULI. This oil is distilled from the leaves of a plant, *Pogostemon Patchouli*, cultivated at Singapore and other Eastern localities. This plant has an interesting history, and the drug was first offered at public sale in London in 1844; it is now imported for European consumption in immense quantities, and it is believed by the Arabs, Chinese, and Japanese to possess prophylactic powers. The oil as found in commerce is of two kinds. The best is that distilled in the East in the neighborhood of the patchouli plantations from selected fresh leaves; the other kind is distilled in Europe from imported leaves; the latter often arrive in a more or less damaged condition, and are frequently adulterated. Oil of patchouli is a thick, brownish-yellow oil with a green tint, and was shown by Gladstone to contain *cærulein*, an intensely blue compound found in oils of absinthium, calamus aromaticus, matricaria, achillea, etc. The oil has the sp. gr. 0·955, and boiling point 257° C. (*P. J. Tr.*, 1880, 410, 813.) It deposits a solid, *patchouli camphor*, which crystallizes in hexagonal prisms, melts at 59° C., and boils at 206° C., while *cadinene*, $C_{15}H_{24}$, remains; oil of cedar and oil of cubebs are frequently used to adulterate the oil, and they may be detected by fractional distillation and their difference in boiling points. Oil of patchouli is used in perfumery mainly for its valuable property of conferring upon other odors lasting qualities; its characteristic and persistent smell when uncombined is usually not popular among Caucasians.

OLEITE. *Sodium Sulphoricinoleate.* This substance may be prepared from castor oil by treating it with sulphuric acid at a low temperature, when a compound of sulphuric and ricinoleic acids is formed. The free sulphuric acid being removed by washing, and any unchanged oil by ether, the resulting sulphoricinoleic acid is then neutralized by sodium hydrate, the finished product being a transparent, jelly-like liquid, with little odor, having an acrid taste, and soluble in water, alcohol, chloroform, and essential oils.

The solvent powers of oleite upon medicinal substances are said to be extraordinary, there being only a few which will not yield to it to a greater or less degree. According to the experiments of Mr. Fred. B. Kilmer (*Proc. A. P. A.*, 1890; *P. J. Tr.*, xx., 1890), its action upon mucous membranes, healthy and diseased skin, cuts, burns, etc., is highly soothing, and it may be taken internally or freely absorbed through the skin without danger. It would appear, therefore, to afford an excellent basis for ointments; but as productions made with it are very sticky, and often liable to harden, it is commonly best used by rubbing the substance with oleite, and then adding 50 per cent. of fatty base.

Phenol sulphoricinate is made by adding pure phenol to sulphoricinic acid; it is a yellowish liquid employed for tuberculous affections. *Phenol and sodium ricinate*—20 per cent. of phenol and 80 per cent. of sodium sulphoricinate—is used as an antiseptic, and in 20 per cent. aqueous solution to destroy *diphtheritic membrane*.

OLEUM CHÆNOCETI. *Dœgling Oil. Dœgling Thran. Huile de Rorqual Rostré*, Fr. The oil derived from the Norwegian whale, *Balæna rostrata*, is said by Gustave Guldberg to possess a lower specific gravity than any other animal oil (0·876 at 15° C.), and also remarkable penetrative properties. It is affirmed that if mixed in equal quantities with chloroform it carries the latter agent through the skin, and enables it to act as a local anæsthetic in *pruritus*, *neuralgia*, etc. Mixed with wax, it is highly recommended as a basis for ointments by the same authority.

OLIBANUM. *Thus. Oliban, Encens*, Fr. *Weihrauch*, G. Olibanum, the *frankincense* of the ancients, was erroneously ascribed by Linnæus to *Juniperus lycia*, L. (now *J. phœnicea*, L.). There are two varieties of olibanum, one coming to Europe from the Mediterranean, and the other directly from Calcutta. These varieties were formerly considered distinct, but recent researches indicate their common origin. In 1843 Captain Kempthorne, of the East India Company's navy, saw the olibanum-tree growing upon the mountains, on the African coast, between Bunder Maryah and Cape Guardafui. According to his statement, it grows on the bare marble rocks composing the hills of that region, without any soil or the slightest fissure to support it, adhering by means of a substance thrown out from the base of the stem. This rises forty feet, and sends forth near the summit short branches, covered with a bright green, singular foliage. The juice, which exudes through incisions made into the inner bark, has at first the color and consistence of milk, but hardens on exposure. (*P. J. Tr.*, iv. 37.) Sir William J. Hooker says that the African olibanum is derived from *Plösslea floribunda* of Endlicher (now *Boswellia papyrifera*, Hochst.), one of the Burseraceæ; but thinks it highly probable that it is furnished by more than one species. (*Ibid.*, 1859, 217.) Mr. Bennett, of the British Museum, has also identified Kempthorne's specimens as *P. floribunda*. But in 1847 Mr. Carter described very closely the oliba-

num district, and procured living specimens, the descendants of which appear still to flourish in the "old gardens" of the Bombay Agri-Horticultural Society. Birdwood asserts (*Trans. Linnæan Soc.*, xxvii.) that no olibanum is obtained in India, all coming from a coast district of Arabia (the same district as that described by Theophrastus), and being the product of a new species of Boswellia, *B. carterii*, Birdwood. It is very likely that several species of Boswellia furnish the olibanum of commerce,—viz., *B. carterii*, Birdw. (furnishes what is known as Luban Bedowi or Luban Sheheri), and *B. frereana*, Birdw. (furnishes Luban Meyeti or Luban Matti). It appears that the resin of *B. papyrifera*, Hochst., is not gathered at all. The product of *B. serrata*, Roxb. (known as *Salaigugul*), is not sent into general commerce, but is employed medicinally only in India.

The Arabian or African frankincense is in the form of yellowish tears, and irregular reddish lumps or fragments. The tears are generally small, oblong or roundish, not very brittle, with a dull and waxy fracture, softening in the mouth, and bearing much resemblance to mastic, from which, however, they differ in their want of transparency. The reddish masses soften in the hand, have a stronger taste and smell than the tears, and are often mixed with fragments of bark and small crystals of calcium carbonate.

The Indian frankincense, or olibanum, consists chiefly of yellowish, somewhat translucent, roundish tears, larger than those of the African, and generally covered with a whitish powder produced by friction. It has a balsamic resinous smell, and an acrid, bitterish, somewhat aromatic taste. When chewed it softens in the mouth, adheres to the teeth, and partially dissolves in the saliva, which it renders milky. It burns with a brilliant flame and a fragrant odor. Triturated with water, it forms a milky imperfect solution. Alcohol dissolves nearly three-fourths of it, and the tincture is transparent. From 100 parts, Braconnot obtained 8 parts of volatile oil, 56 of resin, 30 of gum, and 5·2 of a glutinous matter insoluble in water or alcohol, with 0·8 loss. Various saline substances were found in its ashes. The oil may be separated by distillation, and resembles that of lemons in color and smell. According to Stenhouse, it is isomeric with oil of peppermint, and consists of an oxygenated and a non-oxygenated oil. (*Gmelin's Handbook*, xiv. 390.) Kurbatow showed that the oil consists of *olibene*, $C_{10}H_{16}$, and a portion containing oxygen. Hlasiwetz found the resin to be a uniform substance of the composition $C_{20}H_{30}O_3$. The gum is stated to be identical with arabin.

W. F. Daniell has described an odorous product, used as *frankincense* in Sierra Leone, and obtained from a large tree, growing in the mountainous districts of that region. The tree has been described by Mr. J. J. Bennett in *P. J. Tr.*, 1854, 251, as *Daniella thurifera* (nat. ord. Leguminosæ). According to Dr. Daniell, the juice exudes through openings made by an insect, and, concreting in connection with the woody particles resulting from the boring of the insect, falls at length to the ground, where it is collected by the negroes. (See *A. J. P.*, xxvii. 338.)

Olibanum is stimulant like the other gum-resins, but is now very seldom used internally. According to M. Delioux, of Toulon, however, it affords a cheap, efficient substitute for the balsams of Tolu and Peru. Dose, fifteen grains (0·9 Gm.), which may be increased to a drachm or more. It appears to act more favorably when combined with a little soap. Delioux has also obtained advantage from the inhalation of its fumes, when heated, in chronic *bronchitis* and *laryngitis*. (*Bull. Gén. de Thérap.*, Fév. 28, 1861.) It is chiefly employed for fumigation, and in unofficial plasters.

ONION. *Cepa.* The bulb of *Allium Cepa*, L. (Nat. ord. Liliaceæ.) Fourcroy and Vauquelin obtained from the ordinary onion a white acrid volatile oil containing sulphur, albumen, much uncrystallizable sugar and mucilage, phosphoric acid both free and combined with lime, acetic acid, lime citrate, and lignin. The expressed juice is susceptible of the vinous fermentation. The oil is essentially the same in chemical composition as the oil of *Allium sativum*, L., and consists largely of allyl sulphide, $(C_3H_5)_2S$. (See *Archiv der Pharm.*, 1892, 434.) Perkin and Hummel found *quercetin* in the outer skin of onion bulbs, and the skins have been used in dyeing.

By virtue of its volatile oil the onion taken in moderate quantities is a stimulant to the stomach and promotes digestion, but in large quantities is apt to cause gastric uneasiness. It is slightly rubefacient, said to be diuretic, and belongs among those expectorants to be employed in the advanced stages of subacute *bronchitis* or in chronic *bronchitis*. Remarkable physiological powers have been attached to it by various investigators. As the result of a very elaborate experimental study, Alfred K. Pilacki reached the conclusion that taken freely it depresses nitrogenous metabolism; a conclusion directly opposite to that of Popoff, whose studies led him to the belief that it increases nitrogenous change in the body. It can scarcely be doubted that any apparent influence which it may exert in the direction spoken of is secondary to its action upon digestion.

Onion poultices are somewhat effective as a counter-irritant and nerve stimulant in cases of *bronchitis* or *pneumonia* in young children, with nervous symptoms. According to M. V. Pogorelsky, a decoction made with the outer reddish skin of the bulb is widely used in Russia for the production of abortion. He attributes the ecbolic effect to the presence of allyl sulphide. One or two tumblerfuls of the concentrated dark brown or dark red ingestion are taken at a dose.

ONONIS SPINOSA. Reinsch obtained from this plant *ononin*, $C_{30}H_{34}O_{13}$, a glucoside. *Onocerin*, a di-secondary alcohol, $C_{26}H_{42}(OH)_2$, was isolated by Thoms, who proposes to change its name to *onocol*. (*Archiv. d. Pharm.*, 1897, 28.)

OPHIOXYLON SERPENTINUM. L. (Now *Rauwolfia Serpentina*, Benth. ex Kurz.) (Nat. ord. Apocynaceæ.) In the root of this plant, which is used in East India as a purge and anthelmintic, Prof. Wefers-Bettink found a yellow crystalline principle, *ophioxylin*, melting at 72° C., and possessing the formula $C_{16}H_{12}O_6$; also a volatile oil. (*A. J. P.*, 1890.)

OPOPANAX. A concrete juice usually ascribed to *Pastinaca Opopanax* (L.), *Opopanax hispidum*, Griseb. This species of parsnip, usually called *rough parsnip*, has a thick, yellow, fleshy, perennial root, which sends up annually a strong branching stem, rough near the base, about as thick as a man's thumb, and from four to eight feet in height. The leaves are variously pinnate, with long sheath-

ing petioles, and large, oblong, serrate leaflets, of which the terminal one is cordate, others are deficient at their base upon the upper side, and the whole are hairy on their under surface. The flowers are small, yellow, and form large flat umbels at the termination of the branches. The plant is a native of the Levant, and grows wild in the south of France, Italy, and Greece. When the base of the stem is wounded, a juice exudes, which, when dried in the sun, constitutes the opopanax of commerce. Some authors state that it is obtained from the root. A warm climate appears necessary for the perfection of the juice, as that which has been collected from the plant in France, though similar to opopanax, is of inferior quality. The drug is brought from Turkey. It is said to come also from the East Indies; but Ainslie states that he never met with it in any Indian medicine bazaar. The method of its production is not known with any certainty.

It is sometimes in tears, but usually in irregular lumps or fragments, of a reddish-yellow color, speckled with white on the outside, paler within, and, when broken, exhibiting white pieces intermingled with the mass. Its odor is strong, peculiar, and unpleasant, its taste bitter and acrid. Its sp. gr. is 1·622. It is inflammable, burning with a bright flame. In chemical constitution it is a gum-resin, with an admixture of other ingredients in small proportion. The results of its analysis by Pelletier were, from 100 parts, 33·4 of gum, 42 of resin, 4·2 of starch, 1·6 of extractive, 0·3 of wax, 2·8 of malic acid, 9·8 of lignin, 5·9 of volatile oil and loss, with traces of caoutchouc. Subsequently, Tschirch found opopanax to consist of resin, 19 per cent., ethereal oil, 6·5 per cent.; gum and plant tissues, 70 per cent.; water and loss, 4·5 per cent. (*Archiv d. Pharm.*, 1895, 209.) Water by trituration dissolves about one-half of the gum-resin, forming an opaque milky emulsion, which deposits resinous matter on standing, and becomes yellowish. Both alcohol and water distilled from it retain its flavor; but only a very minute proportion of oil can be obtained in a separate state. Opopanax was formerly employed, as an antispasmodic and deobstruent, in *hypochondriasis*, *hysteria*, *asthma*, and chronic visceral affections, and as an emmenagogue; but it is now scarcely ever used. Dose, from ten to thirty grains (0·64–1·9 Gm.).

OPUNTIA VULGARIS. Mill. (Now *Opuntia Opuntia* (L.), Coult.) (Nat. ord. Cactaceæ.) *Prickly Pear. Figue de Barbarie*, Fr. *Indische Feige*, G. For analyses of fruit of this cactus, see *A. J. P.*, 1884, 3, and 1896, 170.

ORANGE RED. *Orange Mineral. Sandix.* Red lead oxide, prepared by calcining lead carbonate. It is of a lighter color than *minium*, and is used as a pigment.

ORCIN. *Dihydroxytoluene.* $C_6H_3(CH_3)(OH)_2$. This is a white stable powder, of a peculiar sweetish taste and aromatic odor, crystallizing with one molecule of water. It is easily soluble in water, alcohol, and ether, and has a sweet taste. It melts at 56° C. when it contains water, but, deprived of this, melts at 107° C. It boils at 290° C. It is said to resemble resorcin in its local action and to be useful in the same class of skin diseases. According to J. Andeer (*Med. Chron.*, Dec. 1885), it is distinctly antiseptic, and in poisonous doses produces death by a direct action upon the heart-muscle.

OREODAPHNE CALIFORNICA. Nees. (Now *Umbellularia californica*, Nutt.) (Nat. ord. Laurineæ.) *The California Bay Laurel* is an evergreen tree of considerable size, rather abundant throughout the State. Its wood is much prized on account of the beauty of its grain and its immunity from the attacks of insects. The leaves yield about 4 per cent. of a neutral, straw-colored, limpid volatile oil, which has a warm camphoraceous taste and a pungent aromatic odor, resembling somewhat that of a mixture of oils of nutmeg and cardamom. It is soluble in 1000 parts of water, and with alcohol and ether in all proportions. It is said, when inhaled, to cause dizziness and headache. Its chemical characters have been studied by John P. Heamy. (*A. J. P.*, 1875, 105.) He finds it to consist of a pure hydrocarbon, sp. gr. 0·894, boiling at 175° C. (347° F.), and an oxygenated pungent portion, which boils at 210° C. (410° F.). This he calls *oreodaphnol*. *Oreodaphnene* was obtained by distilling oreodaphnol with glacial phosphoric acid. For the reactions, see Mr. Heamy's paper.

OREXIN. *Phenyldihydrochinazoline Hydrochlorate.* $C_6H_4\begin{cases}CH_2.N.C_6H_5\\ \downarrow\\ N=CHHCl\end{cases}$. A complex derivative of quinoline. It forms colorless, odorless, lustrous crystals with bitter, pungent taste, freely soluble in hot water. Orexin was brought forward by F. Penzolt as a true stomachic, increasing not only the appetite but also the power of digestion. According to the experiments of Hofmann, it is entirely free from toxic properties, two grains per pound weight not being sufficient to cause death in the rabbit, although hæmoglobin is shown in the blood under the influence of enormous doses. The general reports from clinicians do not establish the possession by orexin of any extraordinary stomachic powers. Törnell's experiments (*Schmidt's Jahrb.*, Bd. cclvii.) are in evidence that it does not notably increase the gastric secretion. Nevertheless, many cases are recorded in which it has seemed to produce hunger when used in atonic gastric conditions. Excessive acidity and anatomical change are considered contra-indications to its use. Dose, from four to seven grains (0·26–0·5 Gm.), in capsules, from two to three times a day. The *tannate* is said to be superior to the hydrochlorate, as never causing gastric irritation.

ORIGANUM. *Wild Marjoram. Marjolaine sauvage*, Fr. *Wilder Majoran* (*Meiran*), G. Two species of Origanum have been used in medicine, *O. majorana*, L., or sweet marjoram, and *O. vulgare*, L., or common marjoram. The former grows wild in Portugal and Andalusia, and is cultivated as a garden herb in other parts of Europe and in the United States. Some authors, however, consider *O. majoranoides*, Willd., which is a native of Barbary, and closely allied to *O. majorana*, as the type of the sweet marjoram of our gardens. This is by others considered to be simply a form of *O. vulgare*, L. *Sweet marjoram* has a pleasant odor, and a warm, aromatic, bitterish taste, which it imparts to water and alcohol. By distillation with water it yields a volatile oil. It is tonic and gently excitant, but is used more as a condiment than as a medicine. In domestic practice its infusion is employed to hasten the tardy eruption in measles and other exanthematous diseases.

Origanum vulgare, the species formerly recognized by the U. S. Pharmacopœia, is a perennial herb, with erect, purplish, downy, four-sided, trichotomous stems, about eighteen inches high, and

opposite, ovate, entire, pellucid, punctate, somewhat hairy leaves about an inch long, of a deep yellowish-green color. The flowers are of a pinkish-purple or rose color, disposed in roundish, paniced spikes, and furnished with ovate reddish bracts, longer than the calyx. This is tubular and five-toothed, with nearly equal segments. The corolla is funnel-shaped, with the upper lip erect, bifid, and obtuse, the lower trifid, blunt, and spreading. The four stamens are exserted, the stigma bifid and reflexed. The plant is a native of Europe and America. In this country it grows along the roadsides, and in dry stony fields and woods, from Pennsylvania to Virginia, and is in flower from June to October; but it is not very abundant, and is seldom collected for use. It has a peculiar, agreeable, aromatic odor, and a warm, pungent taste. These properties it owes to a volatile oil, which was formerly employed, but has been superseded altogether by the oil of thyme, which is called in commerce oil of origanum. (See *Oleum Thymi.*)

True *oil of origanum* is a yellowish limpid oil, of sp. gr. from 0·900 to 0·950, which smells like camphor, and consists almost entirely of a terpene, $C_{10}H_{16}$, but contains occasionally small amounts of common camphor. It appears not to contain phenols. (Jahns, *Jahresber. der Chem.*, 1880, 1081.) Origanum is gently tonic and excitant, and has been used in infusion as a diaphoretic and emmenagogue, and externally as a fomentation, but is at present little employed.

OROBANCHE VIRGINIANA. L. *Epifagus Americanus.* Nuttall. *Epiphegus Virginiana*, Bart. *Leptamnium Virginianum* (L.), Raf. *Beech-drops. Cancer-root. Orobanche de Virginie*, Fr. *Krebswurz*, G. This is a parasitic, fleshy plant, with a tuberous, scaly base, and a smooth stem, branched from the base, from twelve to eighteen inches high, furnished with small ovate scales, of a yellowish or purplish color, and wholly destitute of verdure. It is found in all parts of North America, growing upon the roots of the beech-tree. The plant has a bitter, nauseous, astringent taste, which is said to be diminished by drying. It has been given internally in bowel affections; but its credit depends mainly upon the idea that it is useful in obstinate ulcers of a cancerous character, to which it was directly applied. Other species of Orobanche, growing in America and Europe, have been employed. They are all parasitic, fleshy plants, without verdure, and of a bitter, nauseous taste. In Europe they are called *broom-rape.* The *O. americana*, L. f. (now *Conopholis americana* (L. f.), Wallr.), and *O uniflora*, L. (*Aphyllon uniflorum*, T. and G.; also *Thalesia uniflora* (L.), Britt.), of America, are used for the same purposes as the species above noticed, and, like it, are called *cancer-root.*

OROXYLUM INDICUM. Vent. (Nat. ord. Bignoniaceæ.) This East India bark is said to be not only a tonic and astringent, useful in *diarrhœa*, but also a powerful sudorific. Naylor and Chaplin have separated from it an acrid principle, and a yellow crystalline substance, *oroxylin.* (*P. J. Tr.*, Sept. 1890.)

ORPIMENT. *King's Yellow.* As_2S_3. A native arsenic trisulphide. It is in masses of a brilliant lemon-yellow color, composed of flexible laminæ, and slightly translucent. It exists in various parts of the world, but is obtained for use from Persia and China. (Guibourt.) It is sometimes mixed with realgar, which gives it a reddish or orange hue. A similar sulphide may be made artificially by passing hydrogen sulphide through a solution of arsenous acid in hydrochloric acid.

Artificial orpiment is prepared for use by fusing together equal parts of arsenous acid and sulphur. (Turner.) In Germany, according to Guibourt, it is prepared by subliming a mixture of these two substances. In this case, however, it retains a large portion of the acid undecomposed, and is therefore highly poisonous. Guibourt found a specimen which he examined to contain 94 per cent. of arsenous acid, and only 6 per cent. of the tersulphide.

Orpiment is an ingredient of certain depilatories. *Atkinson's depilatory* is said to consist of one part of orpiment and six parts of quicklime, with some flour and a yellow coloring matter. (*Ann. der Pharm.*, xxxiii. 348.) But this arsenical sulphide is chiefly used in fireworks and as a pigment.

ORRIS ROOT. *Iris Florentina.* U. S. Secondary List, 1870. *Rhizoma Iridis*, P. G. *Radix Iridis Florentinæ, Radix Ireos. Iris de Florence*, Fr. *Florentinische Violenwurzel, Veilchenwurzel*, G. *Ireos*, It. *Lirio Florentino*, Sp. The root (rhizome) of the Florentine Iris is perennial, horizontal, fleshy, fibrous, and covered with a brown epidermis. The leaves, which spring directly from the root, are sword-shaped, pointed, nerved, and shorter than the stem, which rises from the midst of them more than a foot in height, round, smooth, jointed, and bearing commonly two large white or bluish-white terminal flowers. The calyx is a spathe with two valves. The corolla divides into six segments or petals, of which three stand erect, and the remaining three are bent backward, and bearded within at their base with yellow-tipped white hairs. The fruit is a three-celled capsule, containing many seeds. This plant is a native of Italy and other parts of the south of Europe, where it is also cultivated. The root is dug up in spring, and prepared for the market by the removal of its cuticle and fibres. It is cultivated for commerce chiefly in the neighborhood of Florence, and is exported from Leghorn in large casks.

Florentine orris is in pieces of various form and size, often branched, usually about as thick as the thumb, knotty, flattened, white, heavy, of a rough though not fibrous fracture, an agreeable odor resembling that of the violet, and a bitterish acrid taste. The acrimony is greater in the recent than in the dried root, but the peculiar smell is more decidedly developed in the latter. The pieces are brittle and easily powdered, and the powder is of a dirty white color. Vogel obtained from Florentine orris, gum, a brown extractive, fecula, a bitter and acrid fixed oil or soft resin, a volatile crystallizable oil, and vegetable fibre. According to Landerer, the acrid principle is volatile, separating in the form of a stearopten from water distilled from the root. (*Arch. der Pharm.*, lxv. 302.) The solid oil which is prepared in Europe from orris root by distillation has been examined by Prof. Flückiger. By repeated crystallization from alcohol and treatment with animal charcoal, inodorous crystals were obtained, having the composition $C_{14}H_{28}O_2$ and the properties of myristic acid, whilst the odorous principle remained in the mother-liquor, so that oil of orris must be regarded

as myristic acid impregnated with some volatile oil. The acid does not pre-exist in orris root, and is probably liberated from a fat by the influence of steam. (*A. J. P.*, 1876, 411, also 1885, 133.) According to Hager, the commercial oil has the following properties. At the ordinary temperature it is a pea-yellow acid, resembling basilicon ointment (*Pharm. Germ.*) in color and consistence. It is lighter than water, fuses at from 38°–40° C. (100·4°–104° F.) to a transparent liquid, and commences to congeal at about 28° C. (82·4° F.). Two drops of the fused oil dissolve in ten or twelve drops of warm stronger alcohol, and the solution does not separate at a medium temperature. Three drops of the oil and from twenty to twenty-five drops of concentrated sulphuric acid carefully heated to 30° C. (86° F.) yield a clear red-brown liquid, which, after ten minutes, dissolves in 7 C.c. of 90 per cent. alcohol, with a light violet color, gradually becoming darker. Two drops of a solution of the oil in petroleum benzin evaporated spontaneously leave a residue which, with a magnifying power of from fifty to one hundred diameters, has a radiating appearance after a few hours, and shows distinct crystals after a day. One part of orris oil yields with from three thousand to four thousand parts of weaker alcohol a solution of which a few drops put upon a handkerchief develop a persistent odor of violets. (*A. J. P.*, 1877, 302.) In order to preserve the root from the attacks of insects, it is recommended to put a little chloroform in the bottle in which it may be kept. (*A. J. P.*, 1858, 310.)

Orris root is cathartic, and in large doses emetic, and was formerly employed to a considerable extent on the continent of Europe. It is said also to be diuretic, and to have proved useful in *dropsies*. At present it is valued chiefly for its agreeable odor. It is occasionally chewed to conceal an offensive breath, and enters into the composition of tooth-powders. In the form of small round balls, about the size of a pea, it is used by the French for maintaining the discharge from issues, a purpose to which it is adapted by its odor, by the slight acrimony which it retains in its dried state, and by the property of swelling very much by the absorption of moisture.

ORTHIN. $C_6H_3\begin{cases}OH\\COOH\\HN.NH_2\end{cases}$. *Orthohydrazin-para-oxybenzoate* is very unstable, but unites with hydrochloric acid, forming orthin hydrochlorate, which is stable. This substance was proposed by Kobert (*Deutsche Med. Wochensch.*, 1890) as an antipyretic; but in the experiments conducted by Unverricht, which have been confirmed by Kaufmann, it was found to have comparatively feeble antipyretic action, and to produce in a great many cases sweating and collapse.

ORTHOFORM. *Methyl-para-amido-meta-oxybenzoate.* $C_6H_3(OH)(NH_2)COOCH_3$. A colorless, odorless, and tasteless powder, permanent in the air, slightly soluble in water. Orthoform was introduced into practical medicine by Einhorn and Heinz (*München. Med. Woch.*, 1897). Its chloride is very soluble in water, but is so acid in its reaction as to interfere with its use.

The physiological action of orthoform is only so far made out as to show that, probably on account of its insolubility, it has very little influence upon the system whether given by the stomach or hypodermically, Heinz having found that ninety grains produce no distinct symptoms in the lower animals, and seven hundred grains have been applied to a facial ulcer in a week without injurious effect (*London Lancet*, 1897); also, according to Neumayer (*München. Med. Wochensch.*, xliv. 1897), sixty grains taken by a man in the course of a day produced no symptoms whatever, not even evidences of gastro-intestinal irritation. It has been stated that it is actively antiseptic, but, in the experiments of Lichtwitz and Sabrazes (*Le Bull. Méd.*, xi., 1897), bouillon saturated with it was still capable of nourishing pathogenetic organisms. It is possible that, like iodoform, it undergoes slight decomposition on ulcerated surfaces, and probably exerts an alterative antiseptic influence. Its chief value is, however, dependent upon its action as a local anæsthetic. When brought in contact with sound skin or mucous membrane it has no such influence, and is, therefore, unfit for local use as a surgical anæsthetic. Used in nasal, pharyngeal, or laryngeal disease it seems to be of little value unless there be ulceration. On the other hand, when, as in the case of *burns*, *ulcers*, *abscesses*, etc., it can be brought in contact with exposed sensitive terminal nerve-endings, its influence is decided and prolonged, lasting, on account of its slow solution and consequent non-absorption, for many hours. It may be used either as a dusting powder or in ointment or solution. According to Yonge (*British Med. Journ.*, i., 1898), for many purposes the saturated solution of orthoform in collodion is most effective. In diseases of the larynx the parts may be sprayed with a solution of five grains of orthoform and fifty minims each of alcohol and water, which soon coats the diseased surface. In *keratitis* with ulceration, Boisseau commends an ointment made with one drachm each of lard and lanolin and twenty-four grains of orthoform. In many cases orthoform may also be added with advantage, on account of its anæsthetic properties, to ointments containing medicinal substances. According to Neumayer, its local analgesic action is not accompanied by abolition of the sense of touch. Orthoform is of no value in the treatment of headache, tabetic pains, *sciatica*, or other similar affections, and seems only to be useful in internal medicine when there is *gastrodynia* dependent upon ulceration. From five to ten grains (0·3–0·6 Gm.) may be given from three to four times a day.

Very recently a variety of orthoform, called *Orthoform New*, and defined chemically as *meta-amido-para-oxy-benzoic-acid methyl ester*, has been used by F. Klaussner in *fissures*, *wounds*, *burns*, etc., with alleged great advantage. (*Münch. Med. Wochenschr.*, xlv.)

ORTHOSIPHON STAMINEUS. Benth. *Java Tea.* (Nat. ord. Labiatæ.) This drug occurs in commerce in the form of small, oval, finely toothed, green leaves, rolled up like tea. Van Itallie has discovered in it a volatile oil and a crystalline glucoside, *orthosiphonin*. (*Pharm. Zeit.*, Sept. 1886; see also *Répertoire de Pharm.*, 1887, 191.) It is said to be a powerful diuretic, and is highly recommended in *nephritic colic*, *gravel*, *uric acid diathesis*, and even *ascites*. The dose is from fifteen to fifty grains (0·972–3·2 Gm.) a day.

ORYZA SATIVA. L. (Nat. ord. Gramineæ.) *Rice. Riz*, Fr. *Reiss*, G. This is an annual plant, originally, perhaps, derived from the East Indies, but now very widely cultivated. The rice of com-

merce consists of the seeds of the plant deprived of their husk. Carolina rice was found by Braconnot to contain 85·07 per cent. of starch, 3·60 of gluten, 0·71 of gum, 0·29 of uncrystallizable sugar, 0·13 of fixed oil, 4·80 of vegetable fibre, 5·00 of water, and 0·40 of saline substances. This grain is highly nutritious and of easy digestion, and constitutes the almost exclusive diet of whole nations. Being entirely free from laxative properties, it is admirably adapted to cases of weak bowels, in which there is a strong tendency to *diarrhœa*. Care, however, should be taken that it be boiled till it becomes soft. A decoction of rice, usually called *rice water*, is a good nutritive drink in fevers, and in inflammatory affections of the bowels, lungs, and kidneys.

OS. *Bone.* *Os*, Fr. *Knochen-Asche*, G. *Ossa*, It. *Huesos*, Sp. Under the name of *Os Ustum*, or Bone-ash, the Br. Pharmacopœia formerly recognized "the residue of Bones, which have been burned to a white ash in contact with air. Consists principally of phosphate of calcium, mixed with about 10 per cent. of carbonate of calcium and a little fluoride of calcium, silica, and phosphate of magnesium." When bones are subjected to destructive distillation, in *close* vessels, they are decomposed without alteration of shape, lose about three-sevenths of their weight, become brittle, and are converted into a black substance, containing the earthy salts of the bone, and constituting the species of animal charcoal called *bone-black*. (See *Carbo Animalis*.) The portions which distil over consist of the usual ammoniacal products derived from animal matter, but are especially rich in nitrogenous bases of the pyridine and quinoline series. (See *Ammonii Chloridum*.) Before the distillation is performed, the bones are boiled with water, to separate the fat, which amounts to 5 or 6 per cent.; but gelatin is at the same time extracted, with the effect of rendering the bones less fitted to furnish a good bone-black. In view of this fact, M. Deiss, of Paris, has proposed to extract the fat by carbon disulphide, which gives a product of 10 or 12 per cent., without injuring the bones for subsequent conversion into bone-black. (*A. J. P.*, 1856, 356.) When calcined in open vessels, bones are converted into a white friable substance, consisting of the incombustible part, and commonly called *bone-earth*, or *bone-ash*; and a similar residue is obtained by calcining horns. (See *Cornu Ustum*.) When bones are treated with boiling water, a small portion of the gelatinous matter is dissolved; but when acted on by water in a *Papin's digester*, the whole of it is taken up, and the earthy salts, deprived of their cement, crumble into powder, and become diffused through the solution. When subjected to diluted hydrochloric acid, the earthy salts are dissolved, and the bone softens without losing its shape, and becomes semi-transparent and flexible. The portion remaining unattacked by the acid is the gelatinous tissue, which may be converted into gelatin by long boiling. The hoof bones of the ox, boiled with water, furnish a peculiar oil, called neat's-foot oil.

The bones of different animals, and of the same animal at different ages, vary somewhat in composition. Dry ox-bones, according to Berzelius, consist of bone-gelatin (cartilage of bone) 33·3, calcium bone-phosphate with a little calcium fluoride 57·35, calcium carbonate 3·85, magnesium phosphate 2·05, and soda with a very little sodium chloride 3·45 = 100. Human bones differ somewhat in the proportions of their constituents, and in containing traces of iron and manganese. According to Dr. W. Heintz, however, bones exhausted by water, so as to remove the coloring matter of blood, contain not a trace of iron. Marchand found 1 per cent. of calcium fluoride in human bone. *Calcium bone-phosphate* consists, according to Mitscherlich, of two molecules of acid and three of lime. This analysis, confirmed by Heintz, makes it the tribasic phosphate, $Ca_3(PO_4)_2$.

OSHA ROOT. This is the root of an unknown New Mexican umbellifer. Mr. H. Haupt found in it an acid, *oshaic acid*, closely resembling angelic acid. (*A. J. P.*, 1867, 1868, 1873.)

OSMIC ACID. *Tetroxide of Osmium.* OsO_4. A volatile, very odorous, crystalline compound, produced by the action of nitrohydrochloric acid on osmium or either of its lower oxides. Its vapor is very pungent and poisonous. Claus recommends as an antidote to its action cautious inhalation of hydrogen sulphide. Osmic acid melts to a colorless liquid at 90° C. (194° F.), softening at a temperature of 35° C. (95° F.). It is slowly soluble in water; soluble in alcohol and ether; but these solutions are unstable, depositing black osmic hydrate, $Os(OH)_4$. Osmic acid, on account of its action upon tissues, is largely used in the making of microscopic preparations. We have no definite knowledge as to its influence upon the animal system when given in small doses. It has, however, been used with alleged success in *sciatica* and also in rheumatic affections both as osmic acid and in the form of potassium osmate. By Wildermuth it was used in *epilepsy* in doses of one-sixty-fourth of a grain (0·001 Gm.), repeated until the daily dose amounted to one-quarter of a grain (0·016 Gm.). Stekoulis affirms great success from the injection of fifteen drops of the 1 per cent. solution deep into the gluteal region close to the sciatic nerve in obstinate *sciatica*. At first the injections are repeated daily, afterwards every three or four days, care being exercised never to insert the needle into the same point twice, and to practise injection along the course of the nerve. Severe but very temporary pain is produced. (*Lancet*, Aug. 13, 1887.) Schapiro confirms the value of the remedy. He injects five drops of a solution made by the following formula. Osmic Acid 1 part, Glycerin 40 parts, Distilled Water 60 parts. Auerbach has used parenchymatous injections with alleged success for the destruction of morbid growths. (*Journ. of Laryngology and Rhinology*, June, 1891.)

OXALIC ACID. *Acidum Oxalicum*, *Acide oxalique ou carboneux*, Fr. *Oxalsäure*, *Kleesäure*, G. $H_2C_2O_4,2H_2O$; 126. "In small, colorless, prismatic crystals, odorless and of a very sour taste, slightly efflorescent in dry air, fusible at 98° C. (208° F.), and entirely volatile at a red heat." *

This acid is found both in animals and vegetables. It is generated occasionally in disease, and it may be deposited in the bladder as calcium oxalate, forming the *mulberry calculus*. In vegetables, it occurs in a free state in the bristles of the chick-pea (*Cicer arietinum*, L., nat. ord. Leguminosæ), as an acid potassium oxalate in *Rumex acetosa*, L. (nat. ord. Polygonaceæ),† or common sorrel, *Oxalis acetosella*, L. (nat. ord. Oxalidaceæ), or wood-

* See test-solution of oxalic acid in PART III.

† For fatal poisoning by *Rumex acetosa*, see *Hospital Gazette*, June, 1886.

sorrel, *Chenopodium quinoa*, Willd. (nat. ord. Chenopodiaceæ), *Amarantus caudatus*, L. (nat. ord. Amarantaceæ), *Mesembryanthemum crystallinum*, L. (nat. ord. Ficoideæ), and probably many other plants. It is said to be formed in the leaves. (*Journ. Chem. Soc.*, 1886.) United with lime as raphides, it is abundant in almost every portion of the vegetable kingdom.

Preparation. According to W. Zopf, a certain Saccharomyces (*S. Hausenii*) has the property of producing a fermentation which forms oxalic acid out of sugar; but in the practical arts the sugar is decomposed by nitric acid. Four parts of sugar are acted upon by twenty-four of nitric acid of the sp. gr. 1·24, and the mixture is heated so long as any nitrogen tetroxide is disengaged. A part of the carbon of the sugar is converted into carbonic acid by oxygen derived from the nitric acid, which thereby is reduced to nitrogen tetroxide. The undecomposed nitric acid, reacting with the remaining elements of the sugar, generates oxalic and saccharic acids, the former of which crystallizes as the materials cool, while the latter remains in solution. The crystals being removed, a fresh crop may be obtained by further evaporation. The thick mother-water which now remains is a mixture of saccharic, nitric, and oxalic acids; and, by treating it with six times its weight of nitric acid, the greater part of the saccharic will be converted into oxalic acid. The new crop of crystals, however, will have a yellow color, and contain a portion of nitric acid, the greater part of which may be driven off by allowing them to effloresce in a warm place. It is probable that, in the reaction occurring between nitric acid and sugar, half the carbon of the latter is converted into carbonic acid, and the other half into oxalic acid. This process has, however, been replaced in practice by the "sawdust process."

Many substances, besides sugar, yield oxalic acid by the action of nitric acid; as molasses, rice, potato starch, gum, wool, hair, silk, and many vegetable acids. In every case in which it is thus generated, the proportional excess of oxygen which it contains, compared with every other organic compound, is furnished by the nitric acid. When the acid is obtained from potato starch, this is first converted into starch sugar by the action of sulphuric acid. For details of this process, see 15th edition *U. S. Dispensatory*, p. 90. The yield of oxalic acid from a given quantity of material has been much understated. If properly treated with nitric acid, 100 lbs. of good sugar will yield from 125 to 130 lbs. of oxalic acid, and the same weight of molasses from 105 to 110 lbs.

Certain organic substances yield oxalic acid when heated with potassa. Wood-shavings, if mixed with a solution of caustic potassa and exposed to a heat considerably higher than 100° C. (212° F.), will be decomposed, and partly converted into oxalic acid, which then combines with the alkali. At present most of the oxalic acid of commerce is obtained by heating sawdust with a mixture of caustic soda and potassa. Soda alone will not generate the acid, and potassa is too costly to be used by itself for the purpose; but Dale ascertained that, by mixing the two in the proportion of two molecules of soda to one of potassa, the same or an even better result was obtained than from the latter alone. The mixture of caustic alkalies and sawdust is made into a thick paste and then heated for several hours to a temperature of from 200° C. (392° F.) to 220° C. (428° F.). The gray mass is then washed with sodium carbonate, whereby the potash is removed as carbonate, the less soluble sodium oxalate remaining. This is converted into calcium oxalate by milk of lime, and the calcium salt then decomposed with sulphuric acid. The impure oxalic acid is then purified by recrystallization. Bohlig has suggested an improvement by precipitating the solution of potassium oxalate with magnesium chloride or sulphate. (Bayer, *N. R.*, Aug. 1877.) As the oxalic acid of commerce often contains foreign matter, it requires for certain purposes to be purified. It has sometimes been fraudulently mixed with 25 per cent. of Epsom salt. E. J. Maumené gives the following process for purification, which he says answers better than the method generally recommended. Sufficient hot water is added to the crystals to leave, on the cooling of the solution, from 10 to 20 per cent. undissolved, according to the degree of impurity. The first crystals are put aside. The mother-water is then concentrated; and, if the resulting crystals be submitted to two or three successive crystallizations, the acid will finally be obtained free from alkaline oxalate. (*Journ. de Pharm.*, 1864, 154.) Stolba prefers the method of purification by crystallization from hydrochloric acid (boiling hot). (*Journ. App. Chem.*, Aug. 1874.) Villiers (*Journ. Chem. Soc.*, 1880, 544) prepares anhydrous oxalic acid by dissolving one part of ordinary acid in about twelve parts of warm concentrated sulphuric acid, allowing the oxalic acid to crystallize out.

Properties. Oxalic acid is a colorless crystallized solid, possessing considerable volatility, and a strong, sour taste. Its crystals have the shape of slender, flattened, four- or six-sided prisms, with two-sided summits; and, when exposed to a very dry atmosphere, undergo a slight efflorescence. It is soluble in 4·5 parts of absolute alcohol, in 7 parts of alcohol, and almost insoluble in ether, chloroform, benzol, and benzin. The crystals should dissolve in not less than from eight to ten parts of water at 15° C. (59° F.) (greater solubility indicating contamination with adherent nitric acid).

It fuses in its water of hydration at 98° C. (208·4° F.), although continued exposure to a heat of from 60° C. (140° F.) to 70° C. (158° F.) will render it perfectly anhydrous. Solutions of oxalic acid at 100° C. (212° F.) lose acid by sublimation, and at 157° C. (314·6° F.) it sublimes rapidly. If the heat rise to 160° C. (320° F.), much loss of acid occurs. (Allen, *Commer. Org. Anal.*, 1879, 233.)

It combines with salifiable bases, and forms salts called oxalates. The most interesting of these are the three *potassium oxalates*, severally called *oxalate*, *binoxalate*, and *quadroxalate* (acid potassium oxalate plus free oxalic acid), and the *calcium oxalate*. The binoxalate and quadroxalate, both popularly called *salt of sorrel* or *essential salt of lemons*, are employed for removing iron moulds from linen, and act by their excess of acid, which forms a soluble salt with the ferric oxide constituting the stain. These oxalates are sometimes met with in the market contaminated with free sulphuric acid. Oxalic acid is used for removing ink stains and iron moulds, for cleaning the leather of boot-tops, and for discharging colors in calico-printing. Prussian blue dissolves in aqueous oxalic acid to a clear blue liquid which is often employed as a *blue ink*.

This acid has a very strong affinity for lime, and makes with it an insoluble precipitate consisting

of calcium oxalate, whenever the acid and earth are brought into contact in solution. An aqueous solution forms with solution of lime a white precipitate, insoluble in an excess of oxalic or acetic acid, but dissolved by dilute hydrochloric acid. It is even capable of decomposing calcium fluoride, evolving hydrofluoric acid. (J. W. Slater.) Oxalic acid and its soluble combinations are the best tests for lime; and, conversely, a soluble salt of lime for oxalic acid. In weak solution the acid is said to absorb oxygen and to be converted into carbonic acid; but a strong solution is quite permanent. (*A. J. P.*, 1870, 317.) When lime is searched for, ammonium oxalate is the most convenient test. So strong is the mutual attraction between this acid and lime, that the former takes the latter even from sulphuric acid. Hence the addition of a soluble oxalate disturbs the transparency of a solution of calcium sulphate.

Oxalic acid is distinguished from all other acids by the form of its crystals, and by its solution yielding a precipitate with lime water, insoluble in an excess of the acid or of acetic acid.

Composition. Anhydrous oxalic acid consists of two atoms of carbon, two of hydrogen, and four of oxygen. It is a bibasic acid. When crystallized, two molocules of water must be added, making the molecular weight of the crystals 126. These two molecules of water may be driven off by a regulated heat, by which the acid is made to effloresce. As oxalic acid is the final oxidation product of the diatomic alcohol *glycol*, to which the formula $\begin{matrix}CH_2,OH\\|\\CH_2,OH\end{matrix}$ is given, we may conclude that its structural formula is $\begin{matrix}CO,OH\\|\\CO,OH\end{matrix}$, which explains the readiness with which sulphuric acid splits it up into carbon dioxide, CO_2, and carbon monoxide, CO, by withdrawing H_2O from its formula, and with which oxidizing agents like manganese and lead dioxide change it into carbonic acid. Anhydrous oxalic acid may be obtained by dissolving the ordinary crystals in ten times their weight of sulphuric acid or concentrated nitric acid and cooling the solution.

Medical Properties and Toxicology. Oxalic acid has been strongly recommended by F. Poulet and by A. W. Marsh (*T. G.*, 1891) in *amenorrhœa.* Dose, half a grain (0·032 Gm.) from three to five times a day. Marsh has also found it extraordinarily serviceable in *cystitis.* It is a very active germicide, and, according to Howard A. Kelly, its solution is almost the only practical substance for the perfect disinfection of the surgeon's hands. Attention was first called to it as a poison by Mr. Royston in 1814, and the certainty and rapidity of its action have caused it to be largely used for suicidal purposes. Death has been produced by it in ten minutes. (Case, *Chem. News*, April 24, 1868.) The minimum fatal dose recorded is one drachm (3·9 Gm.). From the general resemblance which the crystallized oxalic acid bears to Epsom salt, many fatal mistakes have occurred in consequence of its being sold for that saline purgative. It is, however, at once distinguished by its sour taste.

Oxalic acid acts on the economy in two principal ways, according as its solution is concentrated or dilute. When concentrated it causes exquisite pain, followed by violent efforts to vomit, then sudden dulness, languor, and great debility, and finally death without a struggle. When dissolved in twenty times its weight of water, it possesses no corrosive and hardly any irritating power, but causes death by acting on the brain, spinal marrow, and heart. It should be noted, however, that the acid, even in weak solution, always exercises a corroding or softening power on the animal tissues.

The morbid appearances caused by oxalic acid are various. In a dissection reported by Dr. Christison, the mucous coat of the throat and gullet had an appearance as if scalded, and that of the gullet could be easily scraped off. The inner coat of the stomach was pultaceous, in many points black, in others red, and that of the intestines similarly but less violently affected. In another case the whole villous coat of the stomach was either softened or removed, as well as the inner membrane of the œsophagus; so that the muscular coat was exposed, and this coat exhibited a dark, gangrenous appearance, being much thickened and highly injected. The stomach usually contains a dark fluid, resembling coffee-grounds, consisting chiefly of altered blood. The tongue and mouth are sometimes white or spotted with white. In a few cases no morbid appearances have been discovered.

In 1879 Kobert and Kürsner announced that in animals oxalic acid may produce glycosuria; this has since been confirmed, and Sarganeck has noted the symptom in human poisoning, so that it is probably a constant phenomenon.

In the treatment of poisoning by oxalic acid, the remedial measures must be employed with great promptitude. Vomiting may be encouraged and the stomach-pump used, but unless the antidote be at hand death will rarely be averted. The proper antidote is chalk or magnesia, mixed with water; and as soon as either can be procured, it must be administered in large and repeated doses. In many cases whitewash or some other preparation of lime can be obtained sooner than chalk, and should be at once administered. These substances act by forming with the poison an insoluble, inert calcium or magnesium oxalate. The soluble salts of oxalic acid, as ammonium oxalate and potassium oxalate, are equally poisonous, and the antidotes for them are the same as for the acid.

The best tests for the detection of oxalic acid in the contents of the stomach, or in the vomited matter, in cases of suspected poisoning, are calcium chloride, copper sulphate, and silver nitrate. The first causes a white precipitate of calcium oxalate, known by its being soluble in nitric acid; the second, a bluish-white precipitate of copper oxalate; and the third, a dense white precipitate of silver oxalate, which, when dried and heated, becomes brown and detonates faintly. When the antidotes have been freely used during life, the poison will be in the state of either calcium or magnesium oxalate. In this case, the oxalate found is to be boiled with a solution of potassium carbonate, whereby a potassium oxalate will be generated; and this must then be examined with the reagents above indicated.

OXALIS ACETOSELLA. L. *Wood-sorrel. Acetosella. Alléluia, Surelle. Pain de Coucou*, Fr. *Sauerklee, Hasenklee*, G. The wood-sorrel is a small, perennial, herbaceous, stemless plant of the nat. ord. Oxalidaceæ, with numerous radical leaves, which are all ternate, and supported upon slender hairy petioles. The leaflets are obcordate, entire, hairy, of a yellowish-green color, but frequently

purplish on their under surface. The scape or flower-stalk, which usually exceeds the petioles in length, is furnished with two scaly bracts near the middle, and terminates in a large white or flesh-colored flower, marked with red streaks. The styles are of the same length as the inner stamens. This plant is a native both of Europe and North America. It selects shady places, such as woods, groves, and hedges, and flowers in May. Other indigenous species of Oxalis possess similar properties to *O. acetosella*. They all have ternate leaves with obcordate leaflets, and, with the single exception of *O. violacea*, L., bear yellow flowers. The whole herbaceous portion may be used.

Wood-sorrel is without smell, and has an agreeable sour taste. It owes its acidity to *acid potassium oxalate* or *potassium binoxalate* (HKC_2O_4), which was formerly separated for use, and sold under the name of *salt of sorrel*. The same salt may be prepared by exactly neutralizing with potassa one part of oxalic acid in solution, then adding one part more of the acid, and evaporating the solution so that it may crystallize upon cooling. Acid potassium oxalate is in rhomboidal crystals, of a sour, pungent, bitterish taste, soluble in forty parts of cold and six parts of boiling water (Kane), and unalterable in the air. *Potassium tetroxalate* or *quadroxalate* is often substituted for the binoxalate. It is prepared in the same manner, except that, instead of one part, three parts of the acid are added to the original proportion neutralized by potassa. Both salts are kept in the shops under the names of *salt of sorrel* and *essential salt of lemons*, and are employed for removing iron mould and ink stains from linen, and sometimes as a test for lime. Both are poisonous, though in a less degree than uncombined oxalic acid.

This and other species of sorrel are refrigerant; and their infusion, or a whey made by boiling them in milk, may be used as a pleasant drink in febrile and inflammatory affections. A solution of the potassium binoxalate is used on the continent of Europe as a substitute for lemonade. It has been recommended by W. H. Taylor as extraordinarily efficacious in *scurvy*. Four grains (0·26 Gm.) of the salt were given three times a day. (*Lancet*, 1869, 777.) The fresh plant, eaten raw, is said to be useful in *scurvy*.

Oxalis crassicaulis, Zucc., a Peruvian species, yields an edible root, and, by expression from its leaves, a very sour and astringent juice, which is employed, in the form of syrup, in *hemorrhages*, chronic *catarrh*, and *gonorrhœa*, with asserted advantage.

OXYCHINASEPTOL. *Diaphtherin.* $C_6H_4(SO_2)\begin{cases}O—NH.C_9H_6(OH)\\O—NH.C_9H_6(OH)\end{cases}$. This substance is made by uniting two molecules of oxychinoline, $C_9H_6N(OH)$, with one molecule of phenol-sulphonic acid, $C_6H_5(HSO_3)OH$. It occurs in yellowish hexagonal crystals, melting at 85° C., very soluble in water and diluted alcohol. Its solution is decomposed by alkalies. According to the researches of Emmerich (*Münch. Med. Wochen.*, 1892), it is much more powerful as an antiseptic than carbolic acid; two-tenths of one per cent. solution is sufficient to kill the comma and diphtheria bacilli in ten minutes, and three-tenths of one per cent. solution destroys the pus organisms in thirty minutes. It is also asserted that it is practically innocuous to higher animals, the subcutaneous injection of five cubic centimetres of a 5 per cent. solution producing no serious effects upon guinea-pigs. It has been used in practical surgery, especially by Kronacher, who has employed from ½ to 1 per cent. solution with great satisfaction for the general purposes of the antiseptic treatment of wounds. Such solution produces no irritation except in some cases a momentary burning. Rohrer (*Corresp. f. Schweiz. Aerz.*, Nov. 1892) commends the remedy as a local application in disease of the nasal mucous membrane. The solution does not stain the hands, but forms on steel instruments a black deposit which is readily washed off.

OXYDENDRUM ARBOREUM, D.C., also (L.) D.C. *Sour-wood. Elk-tree. Sorrel-tree.* (Nat. ord. Ericaceæ.) The leaves of this indigenous tree are said by eclectic physicians to be a powerful diuretic, which has been used very successfully in the treatment of *dropsy*. A semi-solid extract may be made, one part representing five of the drug. Dose, from five to fifteen grains (0·32–0·9 Gm.). Of the fluid extract the dose is from a half to two fluidrachms (1·8–7·4 C.c.).

OXYNAPHTHOIC ACID. *Alpha-naphtholcarboxylic Acid.* $C_{10}H_6\begin{cases}OH\\COOH\end{cases}$. This is the counterpart among the naphthalene derivatives of salicylic acid among the benzene derivatives, and is made in an analogous way by the action of carbon dioxide and sodium upon *a*-naphthol. It forms a white, inodorous, microcrystalline powder fusing at from 185° to 186° C., and is soluble in 30,000 parts of cold water, more readily soluble in alcohol, chloroform, benzol, and oils, both fixed and volatile, also in aqueous solutions of ammonium bicarbonate, which form salts. It is antizymotic, disinfectant, and recommended against phylloxera. Its antizymotic action is said to exceed that of salicylic acid as five to one, and a 5 per cent. ointment has been lauded in *scabies*.

OXYPROPYLENEDIISOAMYLAMINE. Louise affirms that this colorless liquid, which is soluble in alcohol, ether, and oils and insoluble in water, resembles atropine in its action upon the heart, and that it causes great rise of the arterial pressure and of the temperature of the body. (*Lancet*, 1887.)

OZOKERITE. This substance, which is brought from Galicia, in Austria, and from near the Caspian Sea, as well as mined in Southern Utah, in its crude state is a solid, varying in color from a dirty greenish to nearly black. When purified by treatment with sulphuric acid and alkali and subsequent filtration while melted through bone-black or other filtering medium, it is a hard, white, spermaceti-like substance, and is extensively used in England as well as in Austria in the manufacture of candles. (See *Ceresin*.) It is a mixture of natural paraffins. It is said to resemble tar in its therapeutic properties, and, mixed with glycerin or linseed oil, has been employed in skin diseases by Dr. Purdon as a substitute for that remedy. (*Brit. and For. Med.-Chir. Rev.*, 1872, 535. See also *Arch. Gén.*, Avril, 1873, and *Amer. Drug.*, 1892, 40.)

OZONE (O_3) is recognized as an active modification of the element oxygen. It is considered to differ from the common form in being more condensed and at the same time more active. It has a peculiar odor, somewhat resembling that of diluted chlorine. Ozone changes gradually at the ordinary temperature into common oxygen, and at

237° C. the change is instantaneous. It is one of the most powerful oxidizing agents known, attacking and at once destroying organic substances, such as caoutchouc, paper, cork, etc. It also decolorizes most organic pigments. Ozone is somewhat soluble in water, imparting to water its peculiar odor, as well as its oxidizing power. According to Carius, 1000 volumes of water dissolve 4·5 volumes of ozone, and it is much more soluble in certain ethereal oils. The power of these latter as carriers of oxygen and disinfectants is thus explained. At one time ozone was thought to be peroxide of hydrogen, but Marignac and De la Rive demonstrated its true nature. Hautefeuille and Chappins (*Compt.-Rend.*, xciv. 1249) succeeded in producing "liquid ozone" by applying a pressure of 125 atmospheres to richly ozonized oxygen at —100° C. It is stated to be of a dark indigo color.

Ozone has not been obtained free from oxygen; indeed, it is probable that 1 per cent. of ozone is the highest concentration reached in its production. It is prepared by the decomposition of water by the battery, by the passage of the silent electric discharge through air or oxygen, by the slow oxidation of phosphorus in moist air and in other cases of slow combustion, and, lastly, by the action of sulphuric acid upon barium dioxide and potassium permanganate. Poulsen has suggested the following method of making ozone. The apparatus consists of a wide-necked glass jar, with a double cover of porcelain plates, finely perforated; the upper plate closes in the mouth of the jar, while the lower one is inserted in the neck of the jar, about two inches below the other. Through the centre of each of these covers a glass rod passes, terminating at the lower end (which is curved upward) in a small cup for holding a piece of phosphorus: in the jar is placed a given quantity of acidulated water, its level just above the cap containing the phosphorus, which, when the apparatus is not in action, is always submerged. A little potassium permanganate is added to the acid solution, and to produce ozone the phosphorus is raised, by means of the glass rod, just to the surface of the water. Chemical action produces phosphorous acid in the form of fumes by the contact of the phosphorus with the air, and the fumes are seen to rise to a certain height, when they are deflected down upon the solution, into which they are absorbed, and converted into phosphoric acid by being oxidized by the potassium permanganate. Meanwhile, ozonified oxygen is produced, and, passing out through the perforations in the covers, is distributed in the atmosphere. The presence of ozone in the air or in gases is indicated by its action on paper moistened with potassium iodide and starch solution. This is turned blue, and if reddened litmus-paper be moistened with potassium iodide, this is also blued. Another test is found in the use of paper moistened with an alcoholic solution of guaiacum, which is changed to light blue. Its presence in the air is now fully established, although in thickly inhabited districts it is almost always absent, as it is reduced to ordinary oxygen by the organic emanations constantly sent out into the air. In the air of the country, and especially in sea-air, the presence of ozone can almost always be recognized, often, indeed, by its peculiar smell. The probable cause of the formation of ozone in the air has been recently pointed out by Gorup-Besanez, as he has shown that ozone is invariably formed when water evaporates; and it is to this source, rather than to electrical discharges, that the production of ozone must be traced.

PÆONIA OFFICINALIS. L. *Peony. Pivoine*, Fr. *Gichtrose, Pfingstrose*, G. (Nat. ord. Ranunculaceæ.) The *root* of the Garden Peony consists of a caudex about as thick as the thumb, which descends several inches into the ground, and sends off in all directions spindle-shaped tubers, which gradually taper into thread-like fibres, by which they hang together. It has a strong, peculiar, disagreeable odor, and a nauseous taste, which is at first sweetish, and afterwards bitter and somewhat acrid. The odor is lost, or much diminished, by drying. Peony root was in very great repute among the ancients, who used it both as a charm and as a medicine in numerous complaints, particularly *epilepsy*. In modern times it has been used as an antispasmodic. According to Rochebrune (*Toxicol. Afr.*, i.), it contains an active alkaloid, *pæonine*. The dose of the fresh root is from two drachms to an ounce, boiled in a pint of water down to half a pint, which should be taken daily. It is said to be less active when dried. Dose of the expressed juice, one ounce. It is milky, of a strong odor and very disagreeable taste. The *seeds* are roundish-oval, about as large as a pea, externally smooth, shining, and nearly black, internally whitish, inodorous when dry, and of a mild, oleaginous taste. By some authors they are said to be emetic and purgative, by others antispasmodic. Dose, the same as the root. W. Will obtained from an aqueous distillate of the root of the Japanese *Pæonia montana* an aromatic ketone in colorless crystals. (*Ber. d. Chem. Ges.*, xix. 1777.) According to Nagae, this substance has the formula $C_9H_{10}O_3$. (*Ibid.*, xxiv.) It has been prepared by Schimmel & Co., under the name of *peonol*. It has a pleasant aromatic smell, and crystallizes in large needles. No essential oil was found in the root. (Schimmel & Co., *Report*, Oct. 1890.) Dragendorff has found in the seed of the *P. peregrina*, Mill., a fixed oil, an alkaloid, and pæonic acid. (*Jahresb. Pharm.*, 1879.)

PALICOUREA RIGIDA. H. B. K. The leaves of this tree are used in Brazil as a diuretic and diaphoretic. In 1866 Peckholdt found in them an alkaloid and three organic acids. One of these acids, consisting of a yellow, oily liquid with an overpowering odor, was found to be distinctly poisonous, one drop injected into a pigeon being enough to cause death. This was called *myotonic acid*. A crystalline *palicouric acid*, an amorphous tannin, and another amorphous non-toxic bitter principle were also isolated. Santesson has confirmed the presence of an alkaloid. (*Arch. der Pharm.*, 235.)

PALM OIL. *Huile (Beurre) de Palme*, Fr. *Palmöl, Palmbutter*, G. This highly valuable fixed oil is the product of *Elais Guiniensis*, Jacq., a palm growing on the western coast of Africa, and cultivated in the West Indies and South America. It is among the handsomest trees of its graceful family which flourish in the tropical regions of Africa. The oil is obtained by expression from the fruit. It is brought to this country chiefly from Liberia and other places on the African coast, though prepared also in the West Indies, Cayenne, and Brazil. It is not improbable that various species of Palmaceæ contribute to the supply of

this article of commerce. At present the chief ports for its shipment are Cape Palmas and Lagos, prima and secunda Lagos being the choicest varieties. The annual export from the African coast now reaches 50,000 tons, of which the bulk goes to England.

Palm oil has the consistence of butter, a rich, orange-yellow color, a sweetish taste, and an agreeable odor, compared by some to that of violets, by others to that of the Florentine orris. By age and exposure it becomes rancid and of a whitish color. It melts with the heat of the hand, and when perfectly fluid passes readily through blotting-paper. Highly rectified alcohol dissolves it at common temperatures, and in ether it is soluble in all proportions. Its constituents are *tripalmitin* and *triolein*, $C_3H_5(C_{16}H_{31}O_2)_3$ and $C_3H_5(C_{18}H_{33}O_2)_3$. The tripalmitin is converted into *palmitic acid* by saponification, with liberation of glycerin. It appears also that a considerable proportion of this acid, together with some glycerin, exists uncombined in the oil, as ascertained by Pelouze and Boudet; so that the changes which are effected in oils, through the agency of alkalies, in the process of saponification, take place, to a certain extent, spontaneously in palm oil. (*Journ. de Pharm.*, xxiv. 389.) Hence it is more easily saponified than any other fixed oil. Preparatory to saponification, it may be bleached rapidly, according to J. J. Pohl, by heating it quickly to 240° C. (464° F.) and keeping it for ten minutes at that temperature. It loses for a time its peculiar odor by the process, acquiring an empyreumatic smell; but this after a while ceases to be perceived, and the characteristic odor returns. (See *A. J. P.*, xxvii. 346.) Englehart bleaches it in the following manner. 1000 lbs. of the oil are heated in a boiler to 62·2° C. (144° F.) and kept at that temperature until the next day, when it is decanted into a clean vessel, and cooled to a point between 36·6° C. (98° F.) and 40° C. (104° F.). In another vessel 15 lbs. of potassium bichromate are dissolved in 45 lbs. of boiling water; and, when the solution is partially cooled, 60 lbs. of hydrochloric acid are added. This solution is then mixed with the oil, and briskly agitated. In five minutes the color changes to green, through the reduction of the chromic acid; and, with a continuation of the agitation, the chromium oxide separates, and then nothing more is necessary than washing with water to get the oil colorless. (*A. J. P.*, 1868, 333.) Palm oil is said to be frequently imitated by a mixture of lard and suet, colored with turmeric and scented with Florentine orris. It is much employed in the manufacture of a toilet soap, which retains its pleasant odor. Palm oil is emollient, and has sometimes been employed in friction or embrocation, though not superior for this purpose to many other oleaginous substances.

PANAX QUINQUEFOLIUM. L. *Panax*, *U. S.* 1870. *Ginseng*, Fr., G., Sp. *Ginsen*, It. The *ginseng* has a perennial root, which sends up annually a smooth round stem, about a foot high, and divided at the summit into three leaf-stalks, each of which supports a compound leaf, consisting of five or more rarely of three or seven petiolate, oblong-obovate, acuminate, serrate leaflets. The flowers are small, greenish, and disposed in a simple umbel, supported by a peduncle which rises from the top of the stem in the centre of the petioles. The fruit is a kidney-shaped scarlet berry, crowned with the styles and calyx, with two and sometimes three seeds. The plant is indigenous, growing in the hilly regions of the Northern, Middle, and Western States, and preferring the shelter of thick, shady woods. The root is the part employed. This is collected in considerable quantities in Ohio and West Virginia, Minnesota, etc. It is also cultivated. (*A. J. P.*, 1891; *Pharm. Era*, 1895, 359.) It is not used in America, but is exported to China. While supplied with ginseng exclusively from their own country, which furnished the root only in small quantities, the Chinese entertained the most extravagant notions of its virtues, considering it as a remedy for all diseases, and as possessing almost miraculous powers in preserving health, invigorating the system, and prolonging life. It is said to have been worth its weight in gold at Pekin, and the first shipment from North America to Canton yielded enormous profits. John Henry Wilson (*P. J. Tr.*, July, 1888) states that there are in the Chinese market five ginsengs, four of them of Asiatic origin, derived from *Panax ginseng*, C. A. Mey (now *Aralia quinquefolia*, Decne. and Planch.), the fifth the American ginseng from *Panax quinquefolium*. According to E. M. Holmes, *T'ang-shên*, which is used by the poor of China as a substitute for the costly ginseng, is a root of a new campanulaceous plant, *Codonopsis tangshen*, and is exported from Hankow and Oo-chang to the extent of five hundred tons annually. (*P. J. Tr.*, xxi.) For an account of the Chinese methods of using ginseng, see *P. J. Tr.*, vi. 86.

The root is fleshy, somewhat spindle-shaped, from one to three inches long, about as thick as the little finger, and terminated by several slender fibres. Frequently there are two portions, sometimes three or more, connected at their upper extremity, and bearing a supposed, though very remote, resemblance to the human figure, from which circumstance it is said that the Chinese name *ginseng* originated. For an account of the ginseng cultivation in Corea, see *P. J. Tr.*, 1885, 732; and of its collection in the United States, see *Drug. Circ.*, 1884, 33. When dried, the root is yellowish white and wrinkled externally, and within consists usually of a hard central portion, surrounded by a soft whitish bark. It has a feeble odor, and a sweet, slightly aromatic taste, somewhat analogous to that of liquorice-root. It has not been accurately analyzed, but is said to be rich in gum and starch, and contains albumen. S. S. Garrigues obtained from it a peculiar substance, which he named *panaquilon*, and gave the formula $C_{12}H_{25}O_9$. To prepare it he heats a cold infusion so as to separate the albumen, filters, concentrates to a syrupy consistence, precipitates by a concentrated solution of sodium sulphate, washes the precipitate thoroughly with the saline solution, and then treats it with alcohol, which dissolves the principle in question, and yields it on evaporation. To purify it, he dissolves it in water, treats the solution with animal charcoal, again evaporates, and dissolves the residue in absolute alcohol, which is finally distilled off. Panaquilon is an amorphous yellow powder, soluble in water and alcohol, but not in ether, of a sweet bitterish taste, and has the characteristic property that, when treated with strong acids, it is converted into a white substance, insoluble in water, with the escape of carbonic acid and water. Garrigues proposed for this white sub-

stance the name of *panacon*, $C_{11}H_{16}O_4$. (*A. J. P.*, xxvi. 511.) Davydow (*A. J. P.*, 1890, 338) has again investigated these principles discovered by Garrigues, but adds nothing new to our information concerning them. The root is sometimes submitted, before being dried, to a process of clarification, which renders it translucent and horny, and enhances its value as an article of export. The extraordinary medical virtues formerly ascribed to ginseng had no other existence than in the imagination of the Chinese. It is little more than a demulcent, and in this country is not employed as a medicine. Some persons, however, are in the habit of chewing it, having acquired a relish for its taste; and it is chiefly to supply the wants of these that it is kept in the shops.

PANBOTANO BARK. The root of the Mexican leguminous tree *Calliandra houstoni*, Benth., has been highly commended by Valude as an antiperiodic, although Villejean was not able to find in it either an alkaloid or a glucoside. (*Journ. de Sci. Méd. de Lille*, 1890.) Pouchet (*Nouv. Remèdes*, 1896), however, states that he has found in panbotano, besides saponin, an alkaloid which produces death by systolic arrest of the heart. Both Dinau (*Thèse de Paris*, 1896) and Crespin confirm its antiperiodic value. (*Bull. Gén. Thérap.*, Aug. 1895.) A tincture representing two ounces of the root is taken in four doses during twenty-four hours.

PANGIUM EDULE. Reinw. (Nat. ord. Bixineæ.) This East Indian tree, which is said to possess anthelmintic and narcotic properties, and to be capable of causing death, according to Blume, contains an alkaloid resembling *menispermine*.

PAO-PEREIRA BARK. Under this name a bark is employed in Brazil as a febrifuge. It is supposed to be the product of *Geissospermum lævе*, Miers., or of *G. vellosii*, Allem. (Nat. ord. Apocynaceæ.) O. Hesse has found an alkaloid, *geissospermine*, $C_{19}H_{24}N_2O_2 + H_2O$, in it (see *P. J. Tr.*, viii. 648), but he seems to have been preceded in this discovery by Santos. (*A. J. P.*, 1878, 184.) Peretti has discovered in the root a second alkaloid, *pereirine*, $C_{19}H_{24}N_2O$, which, according to Guimaraes (*Brit. Med. Journ.*, vol. i., 1887), in sufficient doses causes paralysis with elevation of temperature, ending in death. It has been given to man as an antiperiodic in doses of thirty grains (1·94 Gm.) a day. (See also *A. J. P.*, 1886, 278.) Later a third alkaloid, *vellosine*, $C_{23}H_{28}N_2O_4$, was found. This forms colorless crystals, melting at 189° C., insoluble in water, easily soluble in alcohol and ether. In concentrated nitric acid it dissolves with a purplish-red color, which is very stable.

PAPAYA. *Melon-tree. Papaw.* The *Carica Papaya*, L. (nat. ord. Passifloreæ), is an herbaceous tree, everywhere cultivated in tropical countries for the sake of its fruit. The tree is both dicœcious and hermaphrodite, reaches a height of about twenty feet, with a cylindrical stem from twelve to twenty inches in diameter, a smooth gray bark, and a shield-like crown of leaves. The fruit in the best varieties attains a size larger than that of a man's head. According to M. Peckholdt (*P. J. Tr.*, Nov. 1879), the milky juice is contained in all parts of the tree, but in such small quantity, save in the unripe fruit, that it is always procured from the latter. One fruit will yield about 33 Gm., which is obtained by scratching through the skin in various places; the process does not interfere with the ripening of the fruit, but it is said that the seeds will not germinate. The milk has an acid reaction, an astringent bitterish taste, and a sp. gr. of 1·023. Upon standing for a few minutes it separates into two parts, an aqueous liquid, and a white, somewhat coagulated, pulpy mass. In the aqueous portion is an albuminous substance, to which the names of *papaïn* and *papayotin* have been given. It is precipitated by alcohol, and, according to M. Wurtz, has not a definite constitution (*Compt.-Rend.*, Aug. 1879), but contains as much as 10·6 per cent. of nitrogen. Rossbach subsequently suggested that this variation might be due to the presence of peptones which he succeeded in separating by dialysis. He found the pure papaïn approximating the general constitution of albuminoid bodies in its composition, as, in addition to carbon, hydrogen, and nitrogen, it contains about 2·61 per cent. of sulphur. In T. Peckholdt's analysis, 100 parts of juice yielded 5·303 parts of papaïn and 4·5 parts of caoutchouc-like substance, besides two resins, fatty materials, malic acid, extractive matter, etc. According to the researches of S. H. C. Martin, papaw juice contains papaïn, which is associated with an albumose, also a milk-curdling ferment. The proteids present in papaw juice were found to be as follows. 1. Globulin, resembling serum globulin in its most important properties. 2. Albumen. 3. β-Phytalbumose, precipitated almost completely by heat, by saturation with neutral salts, but not by dialysis. It differs from the heteroalbumose of Kühne and Chittenden by not being precipitated by dialysis, by copper sulphate, or by mercuric chloride. 4. α-Phytalbumose, soluble in cold or boiling water; not precipitated by saturation with neutral salts, except in an acid solution. This is the vegetable peptone referred to by Vines (*J. Physiol.*, iii.) as hemialbumose. It differs from the protalbumose of Kühne and Chittenden by its non-precipitation by sodium chloride or by copper sulphate. No peptones occur in the juice, but *leucine* and *tyrosine* are present. (*Journ. Chem. Soc.*, 1886, 642; see also *P. J. Tr.*, 1885, 129.) M. Wurtz found that, purified by repeated precipitation from its aqueous solution, 0·1 Gm. of papaïn in alkaline solution at a temperature of 40° C. dissolved in twenty-four hours 17·5 Gm. of moist fibrin by converting it into a peptone. For studies on papaïn by Martin, see *A. J. P.*, 1885 and 1886. Van Rijn extracted from the leaves of *C. papaya* an alkaloid, *carpaine*, $C_{14}H_{25}NO_2$, which is used as a febrifuge. Oefele regards it as a substitute for digitalin.

According to Wurtz, the fibrin is dissolved whether the solvent solution be alkaline or acid. Brunton and Wyatt and also Martin affirm, however, that one-half per cent. of hydrochloric acid will prevent digestion, but Albrecht reasserts that hydrochloric acid hastens the action of the ferment, and states that the official preparation in use in the Paris hospitals is an acid one. In order entirely to convert fibrin into pure peptone so that nitric acid will produce no precipitate, the proportion of the ferment should be as great as 3 per cent., and digestion must continue for forty-eight hours at 50° C. Milk is first coagulated by papaïn, then precipitated, and then digested.

Papaya juice has a tendency to spoil by undergoing a butyric fermentation, but Wurtz found that the addition to it of glycerin preserved it without interfering with its digestive power. Imported in this form, it was a thick milky liquid.

As it now occurs in commerce, papaïn is a grayish, fine powder, which in appearance, odor, and taste strongly suggests pepsin. Recently it has been much used as an internal medicine in *dyspepsia* and *gastric catarrh*, and as a local application for the destruction of false membranes, *warts*, *tubercles*, walls of old sinuses, and even of *epithelioma*. It is not caustic nor astringent, but destroys the part by virtue of its power of dissolving not only muscular but connective tissue. Jacobi affirms (*Therap. Gaz.*, vol. ii.) that diphtheritic membranes are dissolved in a few hours by the hourly application of a mixture of one part of papaïn with two parts each of water and of glycerin. According to Brunton, the dose is from five to ten grains (0·3–0·6 Gm.). Injected into the venous circulation it acts as a powerful poison, a single grain sufficing to kill a rabbit. It is stated that from time immemorial the fresh leaves of the papaya plant have been used by the Indians to wrap meat in to make it tender, and as a dressing to *foul wounds*. Peckholdt says that, taken internally, the juice is reputed to cause intestinal inflammation. No recent observers have noted such influence.

Under the name of *papayotin*, *papaïn*, or *papoid*, the more or less impure ferment of the Carica papaya is put upon the market, and, according to various authorities, it acts powerfully upon starch, converting it into maltose; emulsifies fat, and converts albuminoids into peptones. It is asserted for it that, when the stomach is acid, it is much superior to pancreatin, because its action is not markedly affected by contact with the acid. In experiments made by H. C. Wood with a papoid from one of the most renowned manufacturers no digestion occurred, and it is probable that much of the article of commerce is inert.

PARAFORM. *Paraformaldehyd. Triformol. Trioxymethylene.* This compound, which may be considered as a polymerized formaldehyde, is a colorless, crystalline powder, insoluble in water, used as an intestinal antiseptic in doses of from eight to sixteen grains (0·5–1 Gm.) and externally in surgery as an antiseptic.

PARAMERIA VULNERARIA. *Radlkofer.* (Nat. ord. Apocynaceæ.) This tree yields the *Balsamo de Taguloway* of the Malays. (See *Arch. de Pharm.*, Nov. 1885.)

PARIETARIA OFFICINALIS. L. *Wall Pellitory. Pariétaire, Perce-muraille*, Fr. *Glaskraut*, G. (Nat. ord. Urticaceæ.) A perennial European herb, growing on old walls and heaps of rubbish. It is diuretic and refrigerant, and was formerly used in urinary complaints and *dropsy*, in the form of decoction or of the expressed juice.

PARIS GREEN. *Schweinfurt Green. Aceto-Arsenite of Copper.* $Cu(C_2H_3O_2)_2.3Cu(AsO_2)_2$. This substance, which was originally made for a pigment, is now used to an enormous extent for dusting on potato-vines to destroy the so-called *potato-bug*, or *Colorado beetle*, *Doryphora decemlineata*. It is made by mixing five parts of verdigris with sufficient water to form a thin paste, and adding to this a boiling solution of four parts of arsenous acid in fifty parts of water, keeping the mixture at the boiling temperature, and adding a little acetic acid to cause it to retain a brilliant color. It is rarely found pure in commerce. Numerous cases of poisoning have occurred through carelessness in its use as an insecticide. The treatment would be the same as that for poisoning by arsenic. (See p. 24.) *Lead arsenate* (*Chem. News*, 1896, 17) has been used as a substitute for Paris green.

PARKIA BIGLOBOSA. Benth. (Now recognized either as *P. africana*, R. Br., or *P. roxburghii*, G. Don.) *Houllé. Neretou.* This is an African leguminous tree, from the dried pulp of whose fruit a farinaceous food is prepared by the natives. According to De Rochebrune (*Toxicolog. Africaine*, 1898), it contains a peculiar crystalline alkaloid, *parkine*, which resembles in its physiological activity physostigmine.

PARTHENIUM HYSTEROPHORUS. L. (Nat. ord. Compositæ.) José Torar has found *parthenine* and four other alkaloids, besides *parthenic acid*, in this Cuban plant, which is used by the natives as a febrifuge and antiperiodic. Of the alkaloids, *parthenine* is crystallizable and is apparently the active principle. It has been extracted and studied again by H. Vin Arny (*A. J. P.*, 1890, 121), who believes it to be a bitter glucoside and not an alkaloid. In doses of three grains (0·194 Gm.) it is said to quicken the heart, and in doses of fifteen grains (0·972 Gm.) to slow cardiac action, whilst fifty grains not only lessen the arterial pressure and respiratory frequency but reduce the bodily temperature. In doses of from seven to ten grains (0·45–0·648 Gm.) it is affirmed to be useful in neuralgia. (See *Deutsche Med. Wochen.*, Feb. 1886; *Journ. de Méd de Paris*, March, 1887; *Journ. de Pharm. et de Chim.*, xii., 1885; *A. J. P.*, 1897, 169.)

PARTHENIUM INTEGRIFOLIUM. L. *Prairie Dock.* (Nat. ord. Compositæ.) This is an herbaceous perennial, growing abundantly in the prairies of our Southwestern States. Two ounces of the intensely bitter flowering tops, given in the form of infusion, are thought by Dr. M. Houlton to be equivalent to twenty grains of quinine sulphate as an antiperiodic.

PASSIFLORA INCARNATA. L. (Nat. ord. Passifloreæ.) The indigenous *American Passion Flower* has been used by various practitioners, in doses of from ten to thirty drops of a saturated tincture, in *neuralgias*, *sleeplessness*, *dysmenorrhœa*, as well as in *diarrhœa* and *dysentery*. I. Ott (*Medical Bulletin*, Dec. 1898), finds that it is a depressant to the motor side of the spinal cord, but increases the rate of the respiration; and that it has very little effect upon the circulation, only temporarily reducing the arterial pressure.

PATENT YELLOW. *Mineral Yellow.* A pigment, consisting of lead chloride combined with lead monoxide. It is prepared by mixing common salt and litharge with a sufficient quantity of water, allowing the mixture to stand for some time, then washing out the liberated soda, and exposing the white residue to heat.

PAULO-WILHELMIA SPECIOSA. Hochst. This acanthaceous plant is used by the Aquapine tribe on the Gold Coast, as a fish-poison, under the name of *adubiri*. (*P. J. Tr.*, xx., 1890.)

PEACH LEAVES. *Leaves of Amygdalus Persica.* L. *Persica vulgaris.* Miller. *Prunus Persica.* Stokes. *Pêcher*, Fr. *Pfirsich*, G. The peach-tree is supposed to have been originally brought from Persia, but flourishes everywhere in the warm temperate zone. Peaches are among the most grateful and wholesome of our summer fruits. They abound in saccharine matter, which renders their juices susceptible of the vinous fermentation, and a distilled liquor prepared from them has been

much used, in some parts of the country, under the name of *peach brandy*. The kernels of the fruit resemble, physically and chemically, bitter almonds, for which they are frequently, and without inconvenience, substituted in our shops. The flowers, leaves, and bark also have the peculiar odor and taste of bitter almonds, and yield hydrocyanic acid. The leaves afford a volatile oil by distillation. The distilled water prepared from them was found in one instance to contain 1·407 parts of hydrocyanic acid in 1000, and in another only 0·437 parts in the same quantity. From some experiments it is inferred that the proportion of acid is greatest where there is least fruit. (*A. J. P.*, xxiv. 172.)

Peach oil made from the kernels has found its way into Western Europe from the Levant, and is used in Italy and Southern France largely as an adulterant of almond oil. It is described as of a light yellow color, having the taste and odor of almond oil. It thickens at —9° C. or —10° C., and solidifies at —18° C. The sp. gr. at 15° C. is 0·915; striking with strong nitric acid a dark brown color, with sulphuric acid a dark brown becoming lighter, with solution of zinc chloride a purplish brown; forming with the elaidin test in two hours a mass of butter-like color and consistence. One thousand parts require 189·1 parts of potassa for saponification. (See *P. J. Tr.*, vol. xvi. 798.)

The leaves of the peach are said to be laxative, and, owing to the hydrocyanic acid which they yield, almost all parts of the tree have a sedative influence over the nervous system, and have been used with asserted advantage in *whooping-cough*, irritability of the bladder, etc. The dried leaves may be employed (an ounce to a pint of hot water) in infusion, but the tincture of the inner bark (an ounce to a pint of dilute alcohol), dose, from ten to thirty drops, is possibly preferable. The flowers of the peach are affirmed to be laxative and vermicidal, in half-ounce doses when fresh, given in the form of syrup. Cases of fatal poisoning in children from their use are on record. The peach kernels are distinctly active, and when rubbed up with cold water form an emulsion which may be substituted for cherry-laurel water or other preparations of hydrocyanic acid.

PEARL WHITE. *Pearl Powder.* Bismuth oxychloride prepared for cosmetic use.

PEGANUM HARMALA. L. (Nat. ord. Rutaceæ.) In the seeds of this plant Goebel (1837) found the alkaloid *harmaline*, and Fritzsche (1847) a second alkaloid, *harmine*, which have been restudied by Fischer and Taeuber. (See *A. J. P.*, Feb. 1886, 89.)

PELARGONIUM ODORATISSIMUM. Soland. *Rose Geranium.* (Nat. ord. Geraniaceæ.) This well-known plant, which is a favorite for its odor in our dwellings and conservatories, is a native of Cape Colony, South Africa, but is said to be cultivated extensively in the south of France and in Turkey for the sake of its volatile oil, which is much employed for the adulteration of the otto of roses. According to Guibourt, three species of Pelargonium yield a volatile oil by distillation, closely analogous in smell to that of the rose: the species above named, *P. capitatum*, Soland., and *P. roseum*, Willd. (*Hist. Nat. des Drogues*, 4é ed., iii. 52.) The oil is obtained from the leaves. M. Recluz obtained from thirty-five ounces of *P. odoratissimum*, W., two drachms of a volatile, crystallizable oil. (Mérat and De Lens, *Dict. de Mat. Méd.*, iii. 368.) According to Septimus Piesse, one cwt. yields about two ounces. (See *A. J. P.*, xxvi. 368.) The oil which occurs in commerce, purporting to be the oil of *P. odoratissimum*, is perfectly fluid at ordinary temperatures, of a pale brownish-yellow color, and the characteristic smell of the plant, recalling merely that of the rose. This oil is now much used in perfumery. Mr. Piesse states that, as this oil is used to adulterate that of roses, so is it in its turn adulterated with the cheaper oil of *Andropogon nardus*, cultivated in the Moluccas. (*A. J. P.*, xxvi. 368.) It appears, however, that the oil known as *oil of palmarosa* is the product of *Andropogon schœnanthus*, distilled in India, and this oil is used most largely to adulterate oil of rose and oil of rose geranium. According to Baur, the oil is shipped in large copper flasks from Bombay to the Red Sea, and thence to Constantinople and Kizanlik. Jallard states that the true oil of rose geranium from *P. roseum* is freely soluble in 70 per cent. alcohol. The oils likely to be used to adulterate it are insoluble in this liquid. If, therefore, six drops of the suspected oil be mixed with five C.c. of 70 per cent. alcohol, there should be no separation. (*A. J. P.*, 1878, 260; from *Journ. de Pharm. et de Chim.*) F. W. Semmler (*Ber. der Chem. Ges.*, xxiii. 1098) has shown that the chief ingredient in the various geranium oils is an alcohol, *geraniol*, $C_{10}H_{18}O$, which boils at from 231°–232° C., and has a sp. gr. 0·884 at 15° C. When oxidized by chromic acid mixture, it is changed into *citral*, $C_{10}H_{16}O$, an aldehyde found in many of the essential oils, and this when oxidized by silver oxide yields *geranic acid*, $C_{10}H_{16}O_2$. The geraniol is both free and combined as tiglic acid ester. The oil also contains citronellol. (Schimmel & Co., *Report*, April, 1897.)

PENGAWAR DJAMBI. *Paku Kidang.* This is composed of silky, long, yellow or brownish hairs, very soft, which are obtained in Sumatra from the rhizomes of various ferns, especially of species of the genus *Cibotium*. It has the power of causing rapid coagulation of blood, and, when properly used, of mechanically arresting hemorrhages from capillaries. It has been much used in the physiological laboratories of Europe and this country, and was employed in human medicine during the Middle Ages under the name of *Agnus Scythicus*. The mediæval drug was composed of pieces of the rhizome with the attached scales and petioles so cut as to resemble animals. Attention has been called to the Pengawar Djambi on account of the assertions of Junker of its usefulness during the Franco-German war. (*Lond. Med. Rec.*, Dec., 1887.) It is undoubtedly a very efficient styptic.

PENTAL. *Tri-methyl-ethylene. Isoamylene.* $(CH_3)_2C:CH.CH_3$. A hydrocarbon prepared by distilling amyl alcohol with zinc chloride and treating the distillate with sulphuric acid. A colorless liquid, sp. gr. 0·6783, boiling at 38° C., insoluble in water, and miscible with alcohol, ether, and chloroform. It was proposed as an anæsthetic, but is of little value.

PEREZIA ROOT. This root is obtained from several Mexican plants, *Perezia wrightii*, A. Gray, *P. nana*, A. Gray, and *P. dugesii*, A. Gray. It contains *pipitzahoic acid*, a substance which crystallizes in beautiful golden-yellow needles. R. Anschütz and J. W. Leather obtained from the

dried roots of *Trixis pipitzahoac* an average of 3·6 per cent. of this acid, which melts at from 103°–104° C., sublimes readily, and is easily soluble in alcohol, ether, chloroform, benzol, and glacial acetic acid. The authors confirm the formula given to the acid in 1855,—viz., $C_{15}H_{20}O_3$. It is a quinone, and bears great resemblance, when recrystallized from diluted alcohol, to *oxythymoquinone*, which, recrystallized from the same liquid, is scarcely distinguishable from it. (*A. J. P.*, 1884, 185, and *Pharm. Rundschau*, 1883, 245; *Arch. d. Pharm.*, 1887, 183.)

PERIPLOCA GRÆCA. L. From the bark of this asclepiadaceous plant, growing in the neighborhood of the Black Sea, has been separated by Lehmann and Burschinski (*Archiv der Pharmacie*, 1897) a colorless crystalline glucoside, *periplocin*, soluble in 125 parts of water, freely soluble in alcohol. According to the experiments of Lehmann and Burschinski, it is an active cardiac poison belonging to the digitalis group.

PERONIN. *Peronine.* $C_{17}H_{18}NO_2.O.C_6H_5CH_2HCl$. This is the hydrochloric acid salt of morphine benzyl-ester, produced by replacing the hydrogen of the hydroxyl group in morphine, which is analogous to the phenol-hydroxyl group, with the alcohol radical ($C_6H_5CH_2$). Peronin occurs as a bitter, odorless white powder, consisting of prismatic crystals. At 150° F. it dissolves in water in the proportion of 7·5 : 1000, but dissolves readily in 10 parts of boiling water, the aqueous solutions having a bitter taste and being neutral to litmus. It is further soluble in 218 parts of 95 per cent. alcohol, in 100 parts of methyl alcohol, and in 390 parts of chloroform. Although precipitated from its solutions by the general alkaloidal reagents, peronin differs not only in its solubilities, but also in its behavior towards special reagents, from morphine and codeine.

Peronin was first therapeutically investigated by Schröder (*Therap. Monat.*, 1897), and the conclusion reached that in its medical activities it is intermediate between morphine and codeine. Reports have been made upon it by Nowak (*Therap. Wochensch.*, 1897), by Munk (*Aerztl. Central-Anzeiger*, 1897), and by Eberson (*Therap. Monat.*, 1897). The physiological action of the drug has been partially studied by Mayor (*Revue Méd de la Suisse Romande*, 1898), who finds that it produces in guinea-pigs and rabbits exaggerated reflexes, ending, if the dose have been large enough, in convulsions and death by asphyxia. The lethal dose for rabbits, according to Mayor, is 2·5 Gm. per kilo, or little less than one-third that of codeine. Our present clinical and physiological knowledge is in accord in showing that peronin is a feeble narcotic, which in therapeutic dose has no effect upon the circulation or the digestive apparatus, and which is especially valuable for the purpose of alleviating cough in *phthisis*, chronic *bronchitis*, *emphysema*, *whooping-cough*, and similar affections. It seems also to possess analgesic and hypnotic powers, though distinctly inferior to morphine in activity. The dose is from one-third of a grain to one grain (0·02–0·06 Gm.). Given during the day in the smallest dose mentioned, every five to six hours, in cases with severe cough, it is said to act most favorably in producing comfort during the day and rest at night.

PETROLEUM. *Rock Oil. Oleum Petræ. Coal Oil. Pétrole, Huile minéral*, Fr. *Steinöl, Bergöl*, G. Petroleum is a native mixture of hydrocarbons with very small amounts of oxidation or alteration products admixed. The hydrocarbons may be gaseous, liquid, or solid, and in crude oil, fresh from the wells, all three classes are present. The hydrocarbons belong to several of the homologous series known to organic chemistry. The researches of Pelouze and Cahours, of Warren, and more especially of Schorlemmer, have established the presence of the paraffin series, C_nH_{2n+2}, beginning at methane and continuing through the liquid members, which constitute the bulk of the oil, to the solid hydrocarbons known commercially as "paraffine;" of the olefin series, C_nH_{2n}; and of the benzene series, C_nH_{2n-6}. After the oil has been heated, as in distillation, pyrogenic products form, so that in the residues of petroleum distillation naphtalene, anthracene, and other higher hydrocarbons have been detected. In Caucasian petroleum, Beilstein and Kurbatow (*A. J. P.*, 1880, 612) have also found another homologous series of hydrocarbons, *hexahydrobenzol*, C_6H_{12}, and its homologues.

Pennsylvania petroleum consists, however, chiefly of paraffins, and the individual hydrocarbon making the bulk of illuminating oil is *heptane*, C_7H_{16}. The oxidation products accompanying petroleum constitute only a small fraction of one per cent. usually, and have not been very fully studied. It is known, however, that these alteration products are largely acid in character. Prolonged atmospheric exposure may, however, cause a petroleum to thicken, at least superficially. In this way the semi-solid deposits of California are explained, as well as Rangoon tar and Trinidad pitch or bitumen. When the bitumen is in the solid state it is called *asphaltum*. This is black, dry, friable, and insoluble in water or alcohol. Not infrequently asphaltum exists in nature mixed with more or less of the liquid substance, and this semi-solid mixture is distinguished by the name of *maltha* or *mineral tar*.

Petroleum has been known from the earliest historical period. Herodotus refers to wells of it existing in Zante, and from time immemorial it has been known in the Caucasus, where it was connected with the origin and ceremonies of fire-worship. Until the discoveries of Pennsylvania petroleum, the best-known sources of it were the borders of the Caspian Sea in the Caucasian provinces of Russia, at Amiano in Italy, at Gabian in France, the island of Trinidad in the West Indies, and in the Burman Empire near Rangoon, where vast quantities have been annually raised for many centuries, without any apparent exhaustion of the wells from which it is drawn. Within the limits of the United States it has long been known to exist in a few localities. On the borders of Seneca Lake in the State of New York small quantities of it were collected, and to some extent used in medicine under the name of *Seneca oil*. In Western Pennsylvania, on Duck Creek in Ohio, near Scottsville in Kentucky, and on the Kanawha in Virginia it attracted local attention, and a certain locality in Western Canada had acquired some notoriety by its burning spring. But little attention was paid to it until the year 1859, when, the preparation of oil for burning, distilled from bituminous shales, having proved very profitable, and a strong resemblance having been proved to exist between this and petroleum, enterprise was

directed towards some of the known sources of the latter liquid, and, being greatly stimulated by success, soon led to further and astonishing discoveries. Hitherto the most productive locality of petroleum has been in Western Pennsylvania; but it has been found to exist in great quantities elsewhere, and in fact occupies large portions of a region commencing in Western Canada, and extending, through New York and Pennsylvania, westward into Ohio and Kentucky, and far southward into West Virginia. After the Pennsylvania field, the most productive at present is that of Ohio; but most of the oil produced in this State is from a different geological horizon,—viz., the Trenton limestone,—and contains a persistent sulphur impurity. This renders the Ohio oil (popularly known also as *Lima oil*, from the town of Lima, Ohio) more difficult and expensive to refine. It is hence very largely used in the crude state as *fuel oil*, and as such has been of the greatest industrial value, being shipped by pipe-line or tank-cars to great distances. Valuable deposits are also found in Colorado, near Florence, and elsewhere, and in California, although the oil of this latter State is often quite viscid, and of a bitumen-like character.

In the early days of the petroleum discovery the oil was gathered as it floated on the surface of the water in springs or small streams. In 1859 the first oil-well, the Drake well, was sunk near Titusville, Pa., and the oil-bearing strata were reached at a depth of seventy-one feet, with the result of some eight barrels per day. In 1861 and 1862 the first large flowing wells were struck in drilling for oil. The explanation of these flowing wells is simply that in new territory the gaseous hydrocarbons have accumulated with the liquid oil in such amount that they exert an enormous pressure, causing a flow of oil at the rate of two, three, and in one case as high as eight thousand barrels per day. Often, however, the pent-up gas escapes with enormous force without any accompanying oil. These *gas-wells*, as they are termed, are well known throughout the oil-regions, and they have been utilized on a large scale as sources of gaseous fuel for manufacturing and domestic purposes. The statistics show that the amount of coal displaced by natural gas as fuel in 1887 was approximately 9,055,000 tons, valued at $13,582,500. This amount has reached a maximum, however, and for several years past has been decreasing, as the new gas-wells are unable to equal the rapid loss of strength of the older ones. Thus, in 1888 the value of the natural gas used as fuel was given as $22,629,875, while in 1897 it had decreased to $10,000,000. (*Mineral Industry of the U. S. for* 1897, New York, 1898.) Prof. Sadtler has analyzed numerous samples of this natural gas, and finds it to consist chiefly of methane and its homologues, with traces of the olefines and of carbon monoxide. In one case free hydrogen was present. (*Proc. Amer. Philos. Soc.*, xvi. 585, 1877.) After a well has flowed oil for a time, it will continue to yield on pumping. Indeed, many smaller wells never have flowed, and have to be pumped from the start. In some districts "torpedoing" with nitroglycerin has been largely resorted to after a well has begun to decline in power, in order to increase the flow. The explosion effects this by shattering the sandstone and pebble conglomerate which holds the oil, so that new channels are opened.

Oil-wells are of various depths. The first or Drake well, as stated, was only seventy-one feet deep, while in Butler County the fourth sand-rock was reached only at a depth of from 1500 to 1800 feet, and in Washington County and other localities in the southwestern part of Pennsylvania the oil was obtained from a depth of 2600 feet.

There are two theories as to the origin of petroleum. According to one, it is simply a product of distillation from the bituminous shales which underlie almost the whole of this oil-producing country. The gas and the liquid oil are equally products of this distillation. According to the other, it represents the decomposition of marine plants and animal life which accumulated in these sand-rock formations. These decomposition products may have also been in part subjected to distillation.

Studies by Prof. Engler (*Ber. der Chem. Ges.*, 1888, 1816) on the distillation under pressure (ten atmospheres) of fish oils and of olein and other fats show that large amounts of light oils, composed of pentane, hexane, heptane, octane, and nonane, can be obtained, thus making the second theory very probable.

S. P. Sadtler (*Proceed. Amer. Phil. Soc.*) has shown that linseed oil, distilled under pressure, may be made to yield hydrocarbons of the paraffin series, and has obtained products of all gravities from light benzene to solid scale paraffin. Thus, Engler's theory must be broadened sufficiently to allow of the vegetable seed oils being taken as original sources of petroleum production as well as animal oils.

Crude petroleum is occasionally of a clear color when taken from the earth, but is generally of a greenish color, appearing claret-red by transmitted light. The green color may, however, become so dark as to be almost black. In gravity it varies from 0·865 to 0·777, or from 32·5° to 52° Baumé.

The enormous production of crude petroleum in the last twenty-five years has had the effect of developing a variety of new industries connected with the working or shipping of it. The whole producing area of Western Pennsylvania is now covered with a net-work of wrought-iron pipes, for the conveyance of the oil; and these "pipe-lines" now extend to Cleveland, Buffalo, Pittsburg, New York, Philadelphia, and Baltimore, so that crude oil is pumped from the vicinity of the wells to the seaboard cities, to be refined there or to be exported in bulk. The refining of crude oil, and the working up of the several liquid and solid products that are known commercially, are also immense industries. The production of crude petroleum for the year 1897 amounted to 56,985,643 bbls., and in 1898 to 53,800,000 bbls. The Appalachian field, including Pennsylvania and West Virginia, produces more than 60 per cent. of this, and Ohio 25 per cent. additional. The exports of crude and refined petroleum for the year 1897 were: crude petroleum, 121,864,000 gals.; naphtha and light distillates, 13,704,000 gals.; illuminating oils, 804,446,000 gals.; lubricating oils and paraffin, 52,679,000 gals.; residuum, 12,247,000 gals.; total of all grades, 1,004,941,000 gals., valued at $60,007,000.

After American petroleum the next in importance is Russian or Caucasian. The wells here, although only a few hundred feet in depth, are wonderfully prolific and are veritable "oil fountains." Two of them, the Droobja well and Nobel's

No. 9, each yielded for a time nearly 48,000 bbls. of crude oil per twenty-four hours.

The Bureau of Statistics of the U. S. Treasury Department has recently published a table showing that the world's production of petroleum is now over five billion gallons yearly, of which the United States produces two and one-half billion and Russia two and one-fourth billion, while the remainder is distributed over a dozen countries.

Barbadoes petroleum is a black, nearly opaque, inflammable liquid, of the consistence of molasses, unctuous to the touch, and possessing a bituminous taste and a strong and tenacious odor. Its sp. gr. varies from 0·730 to 0·878. When subjected to distillation it yields naphtha, and leaves a solid residue of asphaltum. It is little affected by alcohol, acids, or alkalies, but dissolves in ether and in the fixed and volatile oils. It consists chiefly of carbon and hydrogen, associated with a little nitrogen and oxygen. *Rangoon petroleum*, also called *Rangoon tar* and *Burmese naphtha*, has a greenish-brown color, a peculiar, rather fragrant odor, and the consistence of goose-fat. It is lighter than water. Heated to 32·2° C. (90° F.) it becomes a very mobile liquid. By distilling it in a current of steam, first at 100° C. (212° F.), and afterwards superheated, Drs. W. de la Rue and H. Müller obtained 96 per cent. of volatile products, solid and liquid. The solid product (*paraffin*) amounted to from 10 to 11 per cent. The liquid product, usually called naphtha, is separable by sulphuric and nitric acids into two series of hydrocarbons, one series removable by these acids, the other resisting their action. The former series contain fewer atoms of hydrogen than of carbon, and embrace, among other hydrocarbons, benzene and toluene. The latter, which form by far the larger portion of the liquid product, are perfectly colorless, almost inodorous, very mobile liquids, not congealable by intense cold. They belong to the paraffin series, and have the general formula C_nH_{2n+2}.

The method of purifying petroleum is analogous to that already described for purifying coal tar. The crude oil is put into large retorts of wrought iron and exposed to a heat rising gradually to between 315·5° C. (600° F.) and 426·6° C. (800° F.), by which all the volatile ingredients are distilled, leaving 10 or 12 per cent. of solid residue, constituting a sort of coke. The liquids thus obtained are comparatively colorless, though still retaining the strong odor of the crude oil. The several fractions are collected separately and show very varying gravity and volatility, and are applied to different uses. An average result of a normal distillation may be stated as follows: gasoline 1½ per cent., refined naphtha 10 per cent., benzin 4 per cent., refined petroleum or kerosene 55 per cent., lubricating oil 17½ per cent., paraffin 2 per cent., loss, gas, and coke 10 per cent. As the greater demand for illuminating oil makes it desirable to get the maximum quantity of this fraction, the distillation is generally so conducted that by the process of "cracking" the yield of burning oil is increased at the expense of the lubricating oil and heavy naphtha. Many distilleries obtain, therefore, from 75 to 80 per cent. of illuminating oil from the crude material. A crude distillate, however, would not be adapted for the purposes of an illuminating oil, so the distillate must be treated with acid. It is placed in the treating tank or "agitator" and 1 or 2 per cent. of strong sulphuric acid is added, when by the aid of an air-blast introduced below the whole is violently agitated. The acid combines with the impurities of the oil and forms a tarry substance, called the "sludge acid," which settles to the bottom, and after the whole has subsided is removed. The oil is then washed with water and again agitated, the process being repeated once or twice. It is then treated with caustic soda solution and again washed. The oil is now clear and almost colorless. It is then placed in large tanks covered with glass frames, where it is "bleached" by the aid of sunlight. It is sometimes atomized or sprayed in these tanks, and is thus brought to the desired fire-test. In most States of the Union the legal fire-test for illuminating oil is 110° F.; that is, it must not evolve inflammable vapors below the temperature of 110° F. Many special brands of illuminating oil have a much higher fire-test, as high even as 300° F.

Lubricating oils, on the other hand, are valued according to their "cold-test;" that is, they must not congeal except at very low temperatures. A lubricating oil, therefore, consists of the heavy liquid hydrocarbons of the paraffin and olefin series, but is free from the solid paraffin.

Medical Properties and Uses. Petroleum is accounted a stimulating antispasmodic, expectorant, and diaphoretic. In large quantities it may prove poisonous, as shown by a case recorded in the *Journ. de Pharm.* (Mars, 1869, 227), in which, after swallowing by mistake a quantity of rectified petroleum, a workman was seized almost immediately with violent inflammation of the throat, with colicky pain, and a desire to vomit, followed in an instant by a fearful tetanic seizure, and a general rigidity, attended by the most frightful cries. After a relaxation of ten minutes the symptoms returned with still greater violence; and life was probably saved only through the prompt action of the powerful emeto-cathartic medicines administered. It is occasionally given in disorders of the chest, when not attended by inflammation. In Germany it has been extolled as a remedy for *tapeworm*. Schwartz's formula in such cases was a mixture of one part of petroleum with one and a half parts of tincture of asafetida, of which forty drops were given three times a day. Externally, petroleum is employed in *chilblains*, *chronic rheumatism*, affections of the joints, *paralysis*, and diseases of the skin, and is said to be very effectual in *psora* and *prurigo*. (See *Petrolatum*, PART I.) It also affords a good antiseptic dressing for wounds. (*Med. Times and Gaz.*, 1870, 101.) It is an ingredient in the popular remedy called *British Oil*. (See note, p. 972.) The dose of Barbadoes petroleum is from thirty drops to a small teaspoonful, given in any convenient vehicle. Rangoon petroleum is probably more active, and should be given in a smaller dose. Crude petroleum is used to a considerable extent as an external application in domestic practice. It is light-colored, thinner in consistence, and less sapid and odorous than the Barbadoes petroleum, and probably contains more naphtha. The finer kinds of petroleum, called naphtha, have been used with alleged advantage in *cholera* by Andreosky, of the Russian army, by Cloquet, physician to the Shah of Persia, and by Moretin, of France. They gave from ten to twenty drops in half a glass of white wine or mint-water. It is affirmed that many cases of *asthma* are much benefited by inhaling petroleum vapors.

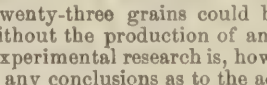
PEUCEDANUM. *Chucklusa.* Two North American species of this genus, of the nat. ord. Umbelliferæ, are used by the Western Indians as food. For an account of them, with analysis, see *A. J. P.*, 1890. They contain *peucedanine.*

PHARBITIS TRILOBA. Miq. *Ipomœa hederacea*, Jacq. The seeds of this Japanese convolvulaceous plant have been chemically examined by Mr. K. Hirano and also by Dr. Y. Inoko, who find that they contain a large proportion of a resinous substance, seemingly identical with *convolvulin*, and acting well as a cathartic in doses of from seven to ten grains (0·454–0·648 Gm.). (*Sei-i-kwai*, 1891.)

PHASEOLUS VULGARIS. L. *Common Bean.* (Nat. ord. Leguminosæ.) Soltsien found an alkaloid, *phaseoline*, in the legumes of the common bean. He, during a toxicological analysis, traced the source of the alkaloid which might, under other circumstances, have been mistaken for a ptomaine, to the beans found in the stomach under examination. The new substance is not crystallizable in the free state, but it crystallizes as a hydrochloride. (*Arch. de Pharm.*, 1884.)

PHENALGIN. *Ammonio-phenylacetamide.* This is a white salt, having a peculiar mild, somewhat ammoniacal taste; forming with water an alkaline solution, and when warmed with strong nitric acid emitting dense ruddy nitric fumes, giving a solution resembling that of picric acid. It is asserted to be an analgesic, especially useful in *dysmenorrhœa*, also anti-rheumatic, and by virtue of its ammonia to act as a vascular stimulant. It is evident, however, that the effect of the ammonia which it contains must be very transient and unimportant. Dose, from three to twenty grains (0·2–1·3 Gm.).

PHENATOL. An antipyretic, said to be a mixture of acetanilid, caffeine, sodium bicarbonate, carbonate, chloride, and sulphate. (*Pharm. Zeit.*, 1894, 784.)



PHENOCOLL HYDROCHLORIDE. *Amido-aceto-para-phenetidin-hydrochloride. Glycocoll-para-phenetidine-hydrochloride.* $C_6H_4\begin{cases}OC_2H_5\\NH.COCH_2NH_2HCl\end{cases}$. This is formed by the action of glycocoll (amido-acetic acid) upon phenetidine. It is a white finely crystalline powder, soluble at 17° C. in sixteen parts of water; also soluble in warm alcohol. Ammonia, alkalies, and alkaline carbonates throw down the pure base phenocoll from the solution of the hydrochloride, in the form of white needles with one molecule of water of crystallization.

According to Kobert, the phenocoll hydrochloride is scarcely at all poisonous to the lower animals, and does not alter the constitution of the blood. Von Mering found that twenty-three grains could be given to the rabbit without the production of any symptoms. Further experimental research is, however, necessary before any conclusions as to the action of phenocoll can be reached, since I. Ott has found that in frogs it is paralyzant to the cerebro-spinal axis, whilst in rabbits it produces cyanosis, reduces the force and frequency of the heart's action, and kills by centric respiratory paralysis. W. S. Carter and D. Cerna found that whilst ordinary doses do not affect the circulation, toxic doses lessen blood-pressure by a direct action on the heart, and first stimulate and then paralyze the cardiac inhibitory system. Oby failed to get any action upon the blood itself. The fall of temperature produced by it is said to be due to lessened heat production. Dr. Hertel (*Deutsch. Med. Wochensch.*, 1891) and Dr. Herzog (*Ibid.*) find that phenocoll in man usually produces no gastro-intestinal irritation or other disagreeable symptoms; that its antipyretic action, when given in doses of a gramme, is a quick, certain one; and that it acts well even in the *hectic fever* of phthisis. It is apt to cause considerable sweating, which can be prevented, however, by the administration of minute doses of atropine. During the taking of the drug the urine becomes of a dark reddish-brown color, but does not contain albumin; both indican and biliary substances have been noted. The observers also noticed the remedy to act very well both in acute and chronic *rheumatism.* The first reports of Hertel, so far as concerns the antipyretic influence of the drug, have been generally confirmed by clinicians, but numerous reports state that as an antirheumatic or antineuralgic phenocoll is inferior. Active antiperiodic powers are attributed to it, and both in Algiers and in Italy it has been used to a considerable extent in *malarial fevers.* As much as seventy-seven grains (5 Gm.) a day have been given without evil results, and in cases of rheumatism less than this amount usually fails to accomplish good results. Cohnheim found that phenocoll appears in the urine in one hour, and can still be recognized nine hours after its ingestion by the ferric chloride test. The dose is from eight to twelve grains (0·518–0·775 Gm.), and is best given in capsules.

Under the name of *Salocoll*, $C_6H_4\begin{cases}OC_2H_5\\NH.COCH_2.NH_2.C_6H_4(OH)COOH\end{cases}$. *Phenocoll Salicylate* has been put upon the market as an antirheumatic. It may be used in the same doses as phenocoll.

PHENOL-BISMUTH. $Bi(OH)_2(C_6H_5O)$. This is a white, neutral, non-irritant and non-toxic powder, almost odorless and tasteless, which, according to its manufacturer, contains 80 per cent. of bismuth in chemical combination with 19 per cent. of phenol. It is stated by M. F. A. Jasenski to be decomposed in the gastro-intestinal tract with absorption of the phenol and escape of the bismuth in great part with the fæces. Jasenski states that even the largest doses (seventy-five grains) of it produce no evidences of phenol poisoning, and the probabilities are that but a small portion of the compound suffers decomposition in the intestinal tract. It has been used in doses of from seven and a half to thirty grains (0·5–2 Gm.) in all forms of gastro-intestinal *catarrhs*, fermentative *dyspepsias*, and similar complaints, as an antiseptic; also to some extent locally in various mucous inflammations.

PHENOLPHTHALEIN.

A coal-tar product used as an indicator in volumetric analysis. Forms a colorless powder almost insoluble in water, soluble in alcohol and in alkalies, with which latter it yields a fine red color, disappearing on addition of excess of acid.

PHENOSAL. *Phenetidine Salicyl-acetate*, $C_6H_4\begin{cases}OC_2H_5\\NH.CO.CH_2.O.C_6H_4COOH\end{cases}$, occurs in colorless crystals of an acidulous taste and sparingly

soluble in water. It contains 57 per cent. of phenetidine and 34 per cent. of salicylic acid, and has been employed in *sciatica*, *migraine*, and *acute articular rheumatism* in doses of from eight to fifteen grains (0·5–0·9 Gm.).

PHENOSALYL. An antiseptic mixture composed of phenol 9 Gm., salicylic acid 1 Gm., lactic acid 2 Gm., menthol 0·10 Gm. It has been used in aqueous solution to sterilize tuberculous expectorations.

PHENYLCHINALDIN, *Methylchinol*, $C_{10}H_8(C_6H_5)N$, is prepared by the action of hydrochloric acid on a mixture of aniline, acetophenone, and aldehyde. The hydrochlorate occurs in colorless crystals, which are readily soluble. It forms with sulphuric acid a crystalline salt, easily soluble in water, with a feeble acid reaction. Leo Fürbringer (*Deutsch. Archiv f. Klin. Med.*, lix. 1897) finds that it produces in the lower animals tremors, violent cramps, fall of temperature, and death (if the dose has been large enough) from failure of respiration. The fatal dose to the rabbit is about fifteeen grains (1 Gm.). It has been used by Julius Mannaberg in *malarial fever* in the dose of seven and a half grains (0·5 Gm.) three times a day, but found to be much inferior to quinine.

PHENYLCHINOLINE. $C_9H_6(C_6H_5)N$. According to Tappeiner (*Deutsch. Archiv für Klin. Med.*, lvi. 1896), the action of this substance on the lower organisms is almost identical with that of quinine, about equal to it in strength.

PHENYLENEDIAMINE. $C_6H_4(NH_2)_2$. *Para-phenylenediamine* and *meta-phenylenediamine* have been physiologically studied by Messrs. Dubois and Vignon (*Compt.-Rend.*, cvii. 533), who find that in doses of 0·01 Gm. per kilogramme they cause in the dog vomiting, diarrhœa, and fatal coma, with peculiar symptoms.

PHENYLHYDRAZINE. $C_6H_5.NH.NH_2$. This is prepared from diazobenzene hydrochloride (resulting from the action of sodium nitrite upon aniline hydrochloride) by reduction with stannous chloride or sodium sulphite. It is a colorless, peculiar-smelling oil solidifying to plate-like crystals melting at 23° C.; difficultly soluble in water; easily soluble in alcohol and ether. The various compound derivatives of this substance have been tested by Heinz (*Berlin. Klin. Wochensch.*, 1890) and others, and found to be too toxic for use in practical medicine. Phenylhydrazine itself has been employed in the following manner as a test for sugar in the urine. (*Fischer's Test.*) One gramme (15·432 grains) of phenylhydrazine hydrochlorate and one and a half grammes (23·13 grains) of sodium acetate are dissolved in ten cubic centimetres (162 minims) of water, this solution is to be mixed with fifty cubic centimetres (1 fluidounce and 332 minims) of the urine, and the mixture boiled in a water-bath for half an hour; an amorphous precipitate will be formed if only a small quantity of sugar be present, but if the sugar be present in considerable quantity a precipitate of minute yellow needles will be deposited. This test was discovered by Prof. Emil Fischer, and is founded on the property of glucose in the urine forming with phenylhydrazine crystals of *phenylglucosazone*.

PHENYLHYDROXYLAMIN. $C_6H_5.NH.OH$. This substance has no known application to the treatment of disease, but requires notice on account of the occasional poisoning by it of those who are engaged in the manufacture of certain chemicals. For cases, see Hirsch and Edel (*Berl. Klin. Wochen.*, xxxii., 1895), L. Lewin (*Archiv für Exper. Path. u. Pharm.*, Bd. xxxv.). The symptoms, which have developed with great suddenness, have consisted of coma, cyanosis, pulselessness, abolition of corneal and pupillary reflexes, chocolate-colored blood, methæmoglobinuria, grayish-blue lips, and intense blue-red surface of limbs. The treatment of these cases should consist in active artificial respiration, together with hypodermic injections of strychnine and of digitalis. For study of the action of the substance upon the blood, see L. Lewin (*Archiv für Exper. Path. u. Pharm.*, Bd. xxxv.).

PHENYLURETHANE. *Euphorin. Phenylcarbamate of Ethyl. Carbamilic Ether.* $C_9O_2H_{11}N.\left(CO\begin{cases}OC_2H_5\\NH(C_6H_5)\end{cases}\right)$. This is a white, crystalline substance, which is made by the action of ethyl chloroformate (or ethylic ether) on aniline. It is almost insoluble in cold water, very soluble in boiling water, alcohol, and ether, and melts at 51° C. It has been physiologically investigated by Giacosa, who finds that its 2 per cent. solution very distinctly hinders or altogether arrests the growth of bacteria and bacilli; that in the frog it produces a general paralysis due to an action upon the nerve-centres; that in the rabbit it causes somnolence, hebetude, albuminuria, gastritis, etc.; but very large doses are required to have any effect, over three hundred grains having been given to a dog without producing inconvenience. It does not form methæmoglobin in the blood. After its ingestion about 8 per cent. of it was found in the urine in the form of *oxyphenylurethane* in combination with sulphuric acid. It has been used by Santoni, Giacomini, and Adler, in doses of from seven to fifteen grains (0·454–0·972 Gm.), as an antipyretic and antirheumatic, also as an analgesic. It has also been employed as an antiseptic dressing in various ulcerations, as a substitute for iodoform. (*Bull. Gén. de Thérap.*, Jan. 1892.)

PHESIN. *Acet-p-phenetidine-sodium sulphonate.* $C_6H_3\begin{cases}O—C_2H_5\\SO_3Na\\NH—CO—CH_3\end{cases}$. Phesin is a sulphonic derivative of phenacetin, which occurs as a reddish-brown, amorphous, tasteless powder, having a slightly irritant salt taste, very soluble in water, affording a Bismarck-brown solution of acid reaction. It has been studied by Von Vámossy and Fenyvessy (*Therap. Monat.*, 1897), who find that it resembles phenacetin very closely in its action, but is characterized by the promptness and shortness of its influence.

PHLORIZIN. *Phloridzin. Phlorrhizin.* $C_{21}H_{24}O_{10} + 2H_2O$. This is a bitter principle, discovered by De Koninck, of Germany, in the bark of the apple-, pear-, cherry-, and plum-trees. It is most abundant in the bark of the root, and derived its name from this circumstance (from two Greek words *φλοιός*, bark, and *ῥίζα*, a root). It is light, white, crystallizable in silky needles, of a bitter taste, soluble in about 1000 parts of cold and in all proportions in boiling water, very soluble in alcohol and methylic alcohol, scarcely soluble in ether, cold or hot, dissolved without change by solutions of the alkalies, deprived of its water of crystallization at 100° C. (212° F.), and fusible at a somewhat higher temperature. The ammoniacal solu-

tion becomes red on exposure to the air on account of the formation of phloridzein, $C_{21}H_{30}N_2O_{13}$. Phlorizin is without acid or alkaline reaction, and belongs to the class of glucosides. When heated with dilute hydrochloric or sulphuric acid, it is converted into sugar and a peculiar substance called *phloretin*, $C_{15}H_{14}O_5$. (See *Chem. Gaz.*, viii. 392.) To obtain phlorizin, the fresh bark of the root of the apple-tree should be selected, as the dried bark is said to contain it in much smaller proportion. The bark is to be boiled for an hour or two successively in two separate portions of water, each sufficient to cover it, and the decoction set aside. At the end of thirty hours they will have deposited a considerable quantity of colored phlorizin, which may be purified by boiling for a few minutes with distilled water and animal charcoal, filtering, repeating this process two or three times, and then allowing the solution to cool slowly. The phlorizin is deposited in the crystalline state. An additional quantity may be obtained by evaporating the decoction to one-fifth of its bulk, allowing it to cool, and purifying the substance deposited in the same manner as before. Rochleder states that the leaves contain a principle, *isophlorizin*, isomeric with phlorizin.

Given to the lower animals in large dose (from seven to ten grains to the pound), phlorizin produces great polyuria, with the elimination of large amounts of sugar, emaciation, polydipsia, and other symptoms of diabetes. (See Coolen, *Archiv. de Pharmacod.*, vol. ii. 1896.) It has been strongly recommended as an antiperiodic, in doses of from ten to fifteen grains (0·648–0·972 Gm.). (*Dublin Quart. Journ.*, 1862.)

PHOSPHINE. *Diamidophenylacridine Binitrate.* This is a reddish powder, whose solution in alkaline fluid is phosphorescent. Notwithstanding its commercial name, it contains no phosphorus. It has been asserted to be a valuable analgesic, but Dujardin-Beaumetz finds it too irritant to the stomach for practical use. (*Gaz. Hebdom.*, June, 1888.)

PHOTOXYLON. This is a nitro-cellulose, which is said to be entirely soluble in a mixture of equal parts of concentrated ether and alcohol. According to Beringer, a 3 per cent. solution leaves on evaporation a very tough collodion-like film. Photoxylon is made from wood-pulp, by methods of nitration similar to those given under pyroxylin, which is its chemical counterpart.

PHYLLANTHUS NIURI. Ottow isolated from this Javanese euphorbiaceous plant *phyllanthin*, $C_{30}H_{37}O_8$, which crystallizes in colorless needles, is intensely bitter, insoluble in water, but soluble in alcohol, benzin, chloroform, and ether.

PHYSALIS ALKEKENGI. L. *Alkekengi. Common Winter Cherry. Alkékenge, Coqueret*, Fr. *Judenkirsche, Schlutte*, G. A perennial herbaceous plant, belonging to the Solanaceæ, growing wild in the south of Europe, and cultivated in our gardens. The fruit is a round red berry, about as large as a cherry, enclosed in the calyx, and containing numerous flat kidney-shaped seeds. All parts of the plant are bitter, especially the leaves and the capsules enveloping the fruit. The berries are very juicy, and have an acidulous, bitterish taste. By drying they shrink, and become of a brownish-red color. The bitter principle, *physalin*, has been isolated by Dessaignes and Chautard. It is obtained by agitating an infusion of the plant with chloroform, which extracts the bitter principle, and yields it on evaporation. To purify it, dissolve it in hot alcohol, add a little animal charcoal, filter, precipitate by water, and wash the precipitate with the same liquid. It is a light powder, white with a shade of yellow, of a taste slight at first, but in the end permanently bitter, very slightly soluble in cold water, somewhat more soluble in boiling water, and very soluble in alcohol and chloroform, especially with the aid of heat. Its composition is $C_{14}H_{16}O_5$. (*Journ. de Pharm.*, 3e sér., xxi. 24.) The berries are said to be aperient and diuretic, and have been recommended in *suppression of urine*, *gravel*, and other complaints of the urinary passages. Gendron recommends them very highly as a febrifuge. (*Arch. Gén.*, xxiii. 536.) They also have been highly commended in *gout*. (*Braithwaite's Retrospect*, Am. ed., No. 46, 214.) From six to twelve berries, or an ounce of the expressed juice, may be taken for a dose; and much larger quantities are not injurious. They are consumed to a considerable extent in some parts of Europe as food. The berries of the *Physalis viscosa*, of this country, are said by Clayton to be remarkably diuretic.

PHYTELEPHAS MACROCARPA, Ruiz. and Pav., or *negrito-palm*, of Ecuador, yields the *Tagud nut*, from which is derived the hard white substance, *vegetable ivory* or *corajo*. The nuts contain a fixed oil which is said to enter commerce. (*Journ. de Pharm.*, xvi.)

PHYTOLACCA ACINOSA. Roxb. (Nat. ord. Phytolaccaceæ.) This plant has long been used in Japan as a diuretic, and is said to be violently poisonous. Mr. C. Nagai has separated from it an amorphous resin, *phytolaccotoxin*, which appears to be a spinal convulsant, and at the same time stimulant to the circulation, probably through the vaso-motor centres. (*Sei-i-kwai Med. Journ.*, April, 1891.)

PICHURIM BEANS. *Sassafras Nuts. Fèves Pichurim, Noix de Sassafras*, Fr. *Pichurimbohnen, Sassafrasnüsse*, G. The seeds of a tree growing in Brazil, Guiana, Venezuela, and other parts of South America. The tree has been supposed to be the *Ocotea Pichurim*, H. B. K. (*Laurus Pichurim*, Willd., now recognized as *Aydendron Laurel*, Nees), but this is denied by F. Nees von Esenbeck; and the product is now referred to the genus of another one of the Laurineæ, Nectandra. There are two varieties of *Nectandra puchury* (Nees and Mart.), one bearing larger and the other smaller fruit, and distinguished as the *major* and *minor*, which yield "Fabæ Pichurim majores and minores." Carson, of the University of Pennsylvania, had specimens of the fruit and other parts of the tree sent him, sufficient to verify the ascription of the pichurim beans to this source. (*A. J. P.*, xxvii. 385.) The beans are the kernels of the fruit separated into halves. They are ovate-oblong or elliptical, flat on one side, convex on the other, of a grayish-brown color externally, chocolate-colored within, of an aromatic odor between that of nutmegs and sassafras, and of a spicy pungent taste. There are two kinds, one about an inch and a half long by half an inch in breadth, the other little more than half as large, rounder, and of a dark brown color. The former were said by Carson to come from Brazil, the latter from Venezuela, and may be severally the product of the varieties of the tree above referred to. (*Ibid.*, 387.) Bonastre has

found them to contain a concrete volatile oil, a fatty matter of the consistence of butter, stearin, resin, brown coloring matter, fecula, gum, sugar, and lignin. Their virtues depend on the volatile oil. The buttery portion, known as *pichurim fat*, amounting to about 30 per cent., contains *laurostearin*, $C_3H_5(C_{12}H_{23}O_2)_3$, and *pichurim camphor*, which, according to Gerhardt, is identical with laurel camphor. In *A. J. P.*, 1851, 1, Procter described a liquid product brought from South America, known as *the native oil of laurel* or *sassafras*, or *aceite de sasafras*, said to be obtained by making incisions in the trunk of a tree growing on the Orinoco. As described by Prof. Procter, it is an oleoresin, of the sp. gr. 0·898, of a light auburn color, a peculiar penetrating odor, and an aromatic, bitterish, pungent, and somewhat camphorous taste. On distillation, almost the whole passes over in the shape of a colorless volatile oil, a small proportion only of resinous matter being left behind. This oleoresin is conjectured to be the same as that employed for adulterating the copaiba exported from Maracaibo. It may be distinguished from copaiba by its ready solubility in alcohol of 0·838, and by the fact that its volatile oil is acted on by potassium. It is believed to be the same product as the "native oil of laurel" described by Pereira, which was obtained from Demerara, and by incisions in a large tree. Prof. Carson, on comparing it with a specimen of oil presented to him as obtained from the same tree with the fruit above mentioned, had no hesitation in considering them as identical, and, therefore, in referring the so-called native oil of laurel to *Nectandra puchury*. Müller, by distilling the oil in contact with sulphuric acid, obtained a greenish-yellow oil possessing the peculiar odor of the beans. By fractional distillation he separated —1, a colorless oil, boiling at 150° C. (302° F.); 2, a colorless oil, boiling between 165° C. (329° F.) and 170° C. (338° F.); both of these oils consist principally of a hydrocarbon, $C_{10}H_{16}$; 3, a greenish-yellow viscid oil, boiling between 235° C. (455° F.) and 240° C. (464° F.), and having the composition $C_{38}H_{58}O_2$; 4, a deep blue oil, having a faint odor, boiling between 260° C. (500° F.) and 265° C. (509° F.). In medical properties the pichurim beans resemble the common aromatics, and may be employed for the same purposes. In South America they are said to be used as a substitute for nutmeg, and have even been called by that name. They are rare in this country. The oil obtained from the tree is said to impart its odor to the perspiration and urine, and to be useful in *rheumatism*, *gout*, etc. The bark is sometimes employed as a tonic and febrifuge.

PICRASMA QUASSIOIDES. Benn. (Nat. ord. Simarubeæ.) The wood of this tree, which grows in the sub-tropical Himalayas, and resembles closely the Ailantus in its appearance, has an intensely bitter taste, and has been proposed as a substitute for quassia. W. Dymock and C. J. H. Warden have found in it a crystalline principle which they believe to be quassin, and to exist in the probable proportion of from 0·02 to 0·03 per cent. The same investigators believe that the drug has in it a peculiar alkaloid. (*P. J. Tr.*, xx. 1889.) A principle analogous to quassin was isolated by Shimoyamo from the bark of *P. eilantoides*. (*Apoth. Zeit.*, 1892, 439.)

PICRIC ACID. *Carbazotic Acid. Trinitrophenol. Nitrophenisic Acid. Acide Picrique, Carbazotique, Nitroxanthique, Jauneamer*, Fr. *Pikrinsäure, Trinitrocarbolsäure, Welter'sches Bitter*, G. $C_6H_2(NO_2)_3.OH$. This acid is obtained by the action of nitric acid on indigo, silk, leather, wool, aloes, benzoin, Australian gum, and other substances, or, as the name indicates, from phenol (carbolic acid). It may be cheaply prepared by adding coal-tar creosote (impure carbolic acid) gradually to strong nitric acid and heating, when, on standing, the picric acid will crystallize out; but in practice it is now almost always made by dissolving crystallized carbolic acid in strong sulphuric acid, and adding either nitric acid or sodium nitrate to the resultant, phenolsulphonic acid. It is in pale yellow shining scales, fusing at 122·5° C. and subliming undecomposed. It is soluble in water, to which it gives a strong yellow color and very bitter taste. Its salts crystallize readily, and explode when heated. The potassa salt is so sparingly soluble that an alcoholic solution of the acid may be used as a test for this alkali. It is largely used in dyeing, producing magnificent yellow colors, and, in connection with indigo or Prussian blue, different shades of green. The salts which picric acid forms with potassa and soda are yellow and bitter, and are much used in the arts. They are, however, violent explosives, and as such have produced very serious consequences. A saturated aqueous solution of picric acid is a very delicate test for albumen. Ammonium picrate is universally preferred for use in medicine. It crystallizes in rhombic scales, which are somewhat more soluble than the corresponding potassium salt. It is explosive when heated or struck. Picric acid and its salts, when in sufficient dose, are poisonous both to man and to the lower animals, though a teaspoonful of ammonium picrate has been taken without the production of other symptoms than those of gastro-intestinal irritation. Toxic doses have been found in the lower animals to stain all the tissues, and produce falling temperature, weakness, diarrhœa, collapse, convulsions, and death. It has a peculiar action upon the blood, changing its color; according to Erb, increasing the number of the white corpuscles and so altering the red blood-disks as to produce the appearance of nucleation. It is a very feeble germicide. The ammonium salt has been used to a considerable extent in the treatment of *malarial diseases*, and has been recommended in *trichiniasis*. Further experience, however, has shown that it has no value in the latter disorder, and is of very little importance as an antiperiodic. The local application of the solution (from 8 per cent. to saturation) of picric acid has been strongly recommended by various surgeons in the treatment of *burns*. In some cases it causes a great deal of pain; and in a number of instances, especially children, it has produced by its absorption vomiting, purging, jaundice, and other symptoms of poisoning. The dose of ammonium picrate, in pill, is half a grain (0·032 Gm.), three times a day; though Erb affirms that from nine to fifteen grains (0·58–0·97 Gm.) may be given in a day without danger.

Ferric Picrate may be prepared by digesting pure crystallized picric acid with an excess of recently precipitated ferric oxide and water at a gentle heat, till the acid has disappeared, filtering, and evaporating the filtrate at a temperature not exceeding 100° C. (212° F.). Thus prepared it is amorphous, reddish brown in mass, lighter colored in powder,

of an astringent and intensely bitter and persistent taste, and readily soluble in water. On account of its bitterness it is best given in pill. (*A. J. P.*, 1863.)

PICROL. *Di-iodo-resorcin-potassium Monosulphonate.* $C_6HI_2(OH)_2SO_3K$. This antiseptic contains 52 per cent. of iodine. It occurs in colorless and odorless crystals having a very bitter taste, soluble in water, glycerin, and ether. It is used as a substitute for iodoform and corrosive sublimate.

PICRORHIZA KURROA. Royle. (Nat. ord. Scrophularineæ.) Under the name of *kali-kutki* a root has long been in use in India, which is stated to be the product of *Picrorhiza kurroa*, Royle. It is said to be a very valuable tonic. (See *P. J. Tr.*, Dec. 1870, 502.)

PIMPINELLA SAXIFRAGA. L. *Small Burnet Saxifrage. Saxifraga. Radix Pimpinellæ*, P. G. *Grand Boucage*, Fr. *Pimpinell, Bibernell*, G. A perennial umbelliferous European plant, growing on sunny hills, and in dry meadows and pastures. The root has a strong, aromatic, yet unpleasant odor, and a sweetish, pungent, biting, aromatic, bitterish taste. Its active constituents are volatile oil and an acrid resin. The volatile oil is described as a golden-yellow, limpid liquid, lighter than water, of penetrating odor recalling parsley, and of biting taste. Buchheim obtained from the alcoholic extract an active principle, which he called *pimpinellin*, insoluble in water and petroleum ether, but soluble in alcohol. It is considered diaphoretic, diuretic, and stomachic, and has been used in *chronic catarrh, asthma, dropsy, amenorrhœa*, etc. The dose in substance is about half a drachm (1·94 Gm.), and in infusion two drachms. The root is used also as a local stimulant in toothache, etc.

PINCKNEYA PUBENS. Michx. (Nat. ord. Rubiaceæ.) A large shrub or small tree, growing in South Carolina, Georgia, and Florida, in low and moist places along the sea-coast. It is botanically allied to the Cinchonas. The bark is bitter, and has been used with alleged advantage in *intermittent fever*. E. H. Naudain (*A. J. P.*, April, 1885) found in it a glucoside, *pinckneyin*, but no alkaloid.

PINEAPPLE. *Ananassa sativa.* Lindl. (Now *Ananas sativus*, Schult. f.) Some years ago Señor V. Marcano discovered that the juice of the ordinary pineapple has the power of digesting proteid vegetable and animal substances. R. H. Chittenden (*Trans. Connecticut Academy*, vol. viii., 1891) found that the fresh pineapple juice is a very constant and powerful digestant of albuminous matters; that the ferment is decidedly active in the presence of either acids or alkaline carbonates, but is most energetic in neutral solution; that the ferment is most active between 50° and 60° C. (122° and 140° F.); still digests at 30° C. (86° F.), but is destroyed at a temperature of 70° C. (158° F.); that the digestion takes place with rapidity; that the ferment, to which the name *bromelin* has been given, is more nearly related to trypsin than to pepsin, forming during its action not only proteoses and peptone, but also leucine and tyrosine.

PIPER NOVÆ-HOLLANDIÆ. Miq. (Nat. ord. Piperaceæ.) The berries of this Australian pepper contain a volatile oil, and are said to be useful in *gonorrhœa* and allied diseases.

PIPER OVATUM. From the leaves of this plant, found growing in Trinidad, Dunstan and Carr (*Chem. News*, 1895, 278) extracted a crystalline principle, *piperovatine*, $C_{16}H_{21}NO_2$. It is insoluble in water, but soluble in alcohol. It is said to act as a depressant of both motor and sensory nerves, and as a stimulant to the spinal cord.

PIPERAZINE. *Arthriticine. Diethylendiamine.* $N_2\left\{\begin{matrix}H_2\\(C_2H_4)_2\end{matrix}\right.$. This is formed by the action of ammonia upon ethylene bromide or chloride. A mixture of bases from this reaction is fractionated, and from the fraction boiling between 130° and 180° C., the diethylendiamine separates on cooling. It forms glassy lustrous tables, melting at from 104° to 107° C., and boils at 145° C. Both the free base and the hydrochlorate are very soluble in water. The latter crystallizes in silky, lustrous, lanceolate forms. In experiments made by Bock upon rabbits, no evidences of stimulating properties could be obtained. The blood-pressure was never increased, but if the dose were large enough was temporarily depressed. In a cold watery solution it is said to dissolve twelve times as much uric acid as will lithium carbonate; and one part of uric acid and piperazine dissolves in fifty parts of water, whilst lithium urate requires 368 times its own weight to dissolve it.

Outside of the body, piperazine acts as a powerful solvent of uric acid; not only when the acid is pulverulent, but also when it is in the form of hard calculi. It was also found by J. H. Brik, of Vienna, that even when the calculi are largely composed of other materials they are broken up by the piperazine affecting the uric acid in them. As piperazine seems in ordinary doses without marked general influence upon the system, and as it does not irritate the mucous membranes of the gastro-intestinal or genito-urinary tract, it would appear to be a very valuable remedy in the treatment of *uric acid gravel* and *calculi*. Van der Klip, as the result of a carefully conducted series of experiments, denies, however, that piperazine is as powerful a solvent of uric acid as is the lithium carbonate. In regard to the action of piperazine upon the system, Van der Klip has found that in the lower animals, in sufficient dose, it produces vomiting, irregular breathing, general muscular weakness, and relaxation; that it also decreases the coagulability of the blood, and has power in checking the action of peptonizing ferments. He further states that it decreases the evolution of oxygen by oxyhæmoglobin. How far piperazine will prove to be of value in uric acid diathesis remains at present uncertain, although the results so far are, on the whole, encouraging. Umpfenbach found it to be a powerful diuretic, and even recommends it in *dropsies*. Dr. Vogt (*Soc. Thérap.*, 1891) affirms, as the result of his investigations, that in doses of fifteen grains (0·972 Gm.) a day it produced a diminution both of the relative and absolute quantity of uric acid. On the other hand, Ebstein and Sprague found that the drug did not affect either the absolute or relative excretion of urea or of uric acid. There is much clinical testimony as to the value of the remedy in *gout* and *rheumatism*, and certainly in those cases in which deposition of urates has occurred the remedy should have a thorough trial. H. C. Wood has found it to act very well in some cases and fail entirely in others. In *stone*, injections of piperazine into the bladder are also worthy of trial. Piperazine may be given in the hypodermic injection of a 2 per cent.

solution, which is said to produce some pain but no abscesses; or, better, fifteen grains (0·972 Gm.) of it may be administered during the day, in a quart of plain or carbonated water. It is so highly hygroscopic that it cannot well be given in pill or powder. The injection of small doses of piperazine immediately into gouty joints is worthy of trial. During the taking of piperazine the urine usually is reddish brown, and the drug can be readily obtained from the urine by methods which are detailed in *New Remedies*, 1892.

PIPERIDINE GUAIACOLATE. *Guaiaperol.* $C_5H_{11}N.C_7H_8O_2$. This substance, which occurs in crystalline needles or flakes soluble in about thirty-two parts of water, is believed by Chaplin and Tunnicliffe, when taken internally, to break up in the duodenum into its constituents, and therefore to unite the tonic and stimulant properties of piperidine with the peculiar powers of guaiacol. According to the investigators mentioned, it is useful in the treatment of *phthisis* in doses of from twenty to twenty-five grains (1·3–1·6 Gm.) three times a day.

PIPI ROOT. The root of the *Petiveria hexaglochin*, Fisch. and Mey. (nat. ord. Phytolaccaceæ), which sixty years ago attracted attention in Europe, is said to have re-entered commerce. It is reported to be a stimulant expectorant and diaphoretic. (*A. J. P.*, Aug. 1887.)

PISCIDIA ERYTHRINA. L. *Jamaica Dogwood.* This is a leguminous tree growing throughout the West Indies, and yielding to commerce a very valuable wood. From time immemorial the bark has been used for catching fish. The leaves, twigs, and root-bark are collected, macerated with the residue from the distillation of rum or with lime water, then transferred into baskets, and the latter dragged up and down the water until the active principle has been extracted and the fish are stupefied.

In 1844 William Hamilton called the attention of the profession to the plant (*P. J. Tr.*, Aug. 1844) as a powerful narcotic and analgesic. The bark of commerce is "in pieces of from two to four inches in length, and from one to two inches wide, and about one-eighth of an inch in thickness. The outer surface of some of the pieces is of a dark gray-brown, while others are of a yellow-brown, with no shade of gray present. The bark is frequently studded with flattened protuberances of a lighter color than the surrounding cork. The central part of the bark is much lighter colored, and, when wet or freshly broken, is of a peculiar blue-green color. The inner part of the bark is of a dark brown color and very fibrous. It has a strong disagreeable odor of opium when broken into pieces. It is acrimonious, and produces a burning sensation in the mouth and pharynx."

E. Hart obtained a neutral principle, $C_{29}H_{24}O_8$, to which he gave the name *piscidin*. When purified by crystallization from alcohol it was obtained in colorless crystals, fusing at 192° C. (377·6° F.), insoluble in water, slightly soluble in ether, easily soluble in benzene, chloroform, and boiling alcohol. (*A. J. P.*, 1883, 369. See also *Ibid.*, Sept. 1898.)

The action of the drug upon the lower animals has been studied by Drs. J. Ott and A. C. Nagle with similar results. (*Jamaica Dogwood*, Parke, Davis & Co., 1881.) The conclusions reached are,—1. It is narcotic to frogs, rabbits, and men. 2. It does not affect the irritability of the motor nerves. 3. It does not attack the peripheral ends of the sensory nerves. 4. It reduces reflex action by a stimulant action on the centres of Setschenow. 5. It produces a tetanoid state by a stimulant action on the spinal cord, and not by a paralysis of Setschenow's centres. 6. It dilates the pupil, which dilatation passes into a state of contraction upon the supervention of asphyxia. 7. It is a salivator. 8. It increases the secretion of the skin. 9. It reduces the frequency of the pulse. 10. It increases arterial tension by stimulation of the vaso-motor centre. 11. This increase of pressure is soon succeeded by a fall, due to a weakening of the heart itself.

The exact practical value of the drug has not been determined, nor are the results produced in man, by doses approaching toxic, known. Dr. Hamilton took a drachm, when laboring under severe toothache, on going to bed. He first felt a violent sensation of heat internally, which gradually extended to the surface, and was followed by profuse perspiration, with profound sleep for twelve hours. On awaking, he was quite free from pain, and without the unpleasant sensations which follow a dose of opium. Various practitioners have reported good results from its use as an anodyne in *neuralgia*, *nervous insomnia*, *whooping-cough*, etc., but in other hands it has failed to do good. H. C. Wood found it in one case of neuralgia to produce great nausea and gastric distress without evincing the slightest narcotic effect. Joseph L. Lemberger offers a formula for the preparation of a *fluid extract*, as follows. Forty-eight troyounces of the bark, in No. 8 powder, are moistened with sufficient of a mixture of three pints of alcohol, half a pint of glycerin, and half a pint of water; it is packed in a percolator, allowed to stand for six hours, and then percolated with the menstruum until three pints of percolate are obtained. (*Drug. Circ.*, 1881, 179.) The dose of the fluid extract is a drachm (3·69 C.c.), to be carefully increased.

PITHECOLOBIUM SAMAN. A shade-tree growing in Japanese coffee plantations which yields a poisonous alkaloid, *pithecolobine*, whose physiological action is analogous to that of sapotoxin.

PIX CANADENSIS. *U. S.* 1880. *Canada Pitch. Hemlock Pitch. Abies canadensis.* Michx. *Pinus canadensis.* L. (Now recognized as *Tsuga canadensis*, Carr., also (L.) Carr.) *Hemlock* or *Hemlock Spruce* of the United States and Canada, when of full growth, is often seventy or eighty feet high, with a trunk two or three feet in diameter, and of nearly uniform dimensions for two-thirds of its length. The branches are slender, and dependent at their extremities. The leaves are very numerous, six or eight lines long, flat, denticulate, and irregularly arranged in two rows. The strobiles are ovate, little longer than the leaves, terminal and pendulous.

The tree is abundant in Canada, Nova Scotia, and the more northern parts of New England, and is found in the elevated and mountainous regions of the Middle States. Its bark is much used for tanning, an extract being made for the purpose. The tree contains much less juice than some other of the Pinaceæ, and very little flows from incisions made into its trunk. But in the trees which have attained their full growth, and are about or have begun to decay, the juice exudes spontaneously, and hardens upon the bark, in consequence of the partial evaporation or oxidation of its volatile oil.

The bark thus incrusted is stripped from the tree, broken into pieces, and boiled in water. The pitch melts, rises to the surface, is skimmed off, and is still further purified by a second boiling in water. Hemlock pitch is hard, brittle, quite opaque, of a dark reddish-brown color, becoming still darker by exposure to the air, of a weak peculiar odor, and scarcely any taste. It softens and becomes adhesive with a moderate heat, and even at ordinary temperatures takes the form of the vessel containing it, and melts at 198° F. Its constituents are resin and a minute proportion of volatile oil. It is sometimes known by the incorrect name of *hemlock gum*. Canada pitch is a gentle rubefacient, closely analogous to Burgundy pitch in its properties, and employed for precisely the same purposes. It is, however, more readily softened by heat, and is sometimes almost too soft for convenient application at the temperature of the body. A volatile oil obtained from *Abies canadensis*, and called *oil of spruce* or *oil of hemlock*, has been employed to produce abortion, with the effect of endangering the life of the female. (J. S. Paige, *N. Y. Journ. of Med.*, viii. 184.)

The U. S. Pharmacopœia of 1880 gave the following directions for preparing the *Hemlock* or *Canada Pitch Plaster*. (*Emplastrum Picis Canadensis, U. S.* 1880.) "Canada Pitch, *ninety parts* [or nine ounces av.]; Yellow Wax, *ten parts* [or one ounce av.], To make *one hundred parts* [or ten ounces av.]. Melt them together, strain the mixture, and stir constantly until it thickens on cooling."

PIXOL is a form of wood-tar, soluble in water, made by warming three parts of wood-tar and one part of green soap together and gradually adding three parts of a 10 per cent. solution of potassium hydrate with stirring. It is a clear dark brown syrupy liquid. The disinfecting power of a 5 per cent. solution is said to be not less than that of a 5 per cent. solution of carbolic acid.

PLANTAGO MAJOR. L. *Plantain. Rib-grass, Rib-wort, Ripple-grass. Plantain*, Fr. *Wegerich*, G. (Nat. ord. Plantaginaceæ.) The leaves are saline, bitterish, and austere to the taste; the root saline and sweetish. The common plantain weed was formerly considered refrigerant, diuretic, deobstruent, and somewhat astringent. The ancients esteemed it highly, but it is at present never used, except it be externally in domestic practice as a stimulant application to sores. The leaves are put on whole or bruised in the form of a poultice. *Plantago media* and *P. lancifolia*, or *rib-grass*, which are also indigenous, possess properties similar to those of *P. major*, and may be used for the same purposes.

Theo. Koller, in 1868, obtained from the leaves of *Plantago major*, *P. lanceolata*, and *P. media*, chlorophyll, resin, wax, albumen, pectin, citric acid, and oxalic acid. David Rosenbaum found in the leaves of *P. major*, wax, chlorophyll, resin, and a notable quantity of calcium oxalate. (*A. J. P.*, 1886, 418.) J. F. Strawinski found in the rhizome a substance which he believes to be either phlobaphene or protocatechuic acid. (*A. J. P.*, 1898, 189.)

Semen psyllii are the seeds of several species of European Plantago. The best are those of *Plantago psyllium*, or *fleawort*, which grows in the south of Europe and in Barbary. They are small, about a line long by half a line in breadth, convex on one side, concave on the other, flea-colored, shining, inodorous, and nearly tasteless, but mucilaginous when chewed. They are demulcent and emollient, and may be used internally and externally in the same manner as flaxseed, which they closely resemble in medical properties. *Spogel seed*, used as a demulcent in intestinal irritation, is derived from *P. Isphagula*. (See *Journ. de Méd. de Paris*, Sept. 1887.)

PLATINUM. *Platine, Orblanc*, Fr. *Platin*, G. The most useful salt of platinum is the chloride, $PtCl_4 5H_2O$, which may be obtained by mixing an aqueous solution of chloroplatinic acid, H_2PtCl_6, with a solution of silver nitrate: a precipitate containing the silver, combined with some platinum and chlorine, separates, and the yellowish-red solution yields on evaporation fine large red crystals of platinum chloride. The compound usually called platinum chloride is said by Roscoe and Schorlemmer to be chloroplatinic acid, $H_2PtCl_6,6H_2O$, and is made by dissolving the metal in nitro-hydrochloric acid, and evaporating with hydrochloric acid until all of the nitric acid is removed. In 1826 Prof. Gmelin, of Tübingen, made experiments to determine the action of this metal on the economy. In 1841 Dr. Ferdinand Hoefer published some observations on the same subject. The latter experimented chiefly with the chloride, formerly called bichloride, and the double platinum and sodium chloride. They are both poisonous: the chloride in the dose of fifteen grains, the double chloride in that of thirty grains. When a concentrated solution of the chloride is applied to the skin, it produces violent itching, followed by an eruption; administered internally, it irritates the mucous membrane of the stomach and occasions headache. The double chloride has no action when externally applied, and, when given internally, operates on the system in a less sensible manner than the chloride. It possesses the power of augmenting the urine. Dr. Hoefer ranks the preparations of platinum with the alteratives, by the side of those of iodine, arsenic, and gold. He considers them particularly suited to the treatment of *syphilitic diseases:* the chloride to cases of long standing and inveterate, the double chloride to those which are recent. The dose of the chloride is from half a grain to two grains (0·032–0·130 Gm.) twice a day, given in pill. Eight grains may be made into sixteen pills, with a drachm of the extract of guaiacum wood of the French Codex, and sufficient powdered liquorice root. Of these, one, two, or three may be taken morning and evening. The double chloride may be prepared by dissolving five grains of the chloride and eight of pure sodium chloride in seven fluidounces of gum-water, and the whole may be taken by tablespoonfuls in the course of twenty-four hours. For frictions on *indolent ulcers*, Dr. Hoefer used an ointment composed of sixteen grains of the chloride, thirty-two grains of extract of belladonna, and an ounce of lard. (*Journ. de Pharm.*, xxvii. 213.)

PLUMBAGO EUROPÆA. L. *Leadwort. Dentellaria.* (Nat. ord. Plumbaginæ.) A perennial, herbaceous plant, growing in the south of Europe. It has an acrid taste, and, when chewed, excites a flow of saliva. This is particularly the case with the root, which has been long used to relieve toothache; hence its French name *dentelaire*. A decoction of the root in olive oil has been highly recommended for *itch*. A crystallizable, acrid principle, called *plumbagin*, has been

extracted from the root by Dulong. (*Journ. de Pharm.*, (2) xiv. 441.) *Plumbago zeylanica* is said to be a very powerful diaphoretic.

PLUMBI OXIDUM RUBRUM. *Red Oxide of Lead. Red Lead. Minium*, P. G. *Deutoxide de Plomb, Oxide Rouge de Plomb, Minium*, Fr. *Mennige*, G. *Minio*, It., Sp. Red lead is prepared on the large scale in a furnace, with the floor slightly concave and the roof arched, presenting a general resemblance to a baker's oven. The lead is placed on the floor, and gradually raised to a red heat, whereby it melts and becomes covered with a pellicle of monoxide, which is removed by means of a long iron scraper; and the pellicles, as they successively form, are scraped off until the whole of the metal has been converted into them. The product is subjected to further calcination, with occasional stirring, for some time, in order to oxidize any particles of metallic lead; it is thus rendered yellow, and constitutes *lead monoxide*, or *massicot*.

This is taken out of the furnace, thrown upon a level pavement, and cooled by being sprinkled with water. It is next reduced to fine powder by trituration and levigation, and dried, and in this state is introduced into large, shallow, square tin boxes, which are placed in another furnace, closed from the air, and heated nearly to redness, the heat being allowed gradually to fall during a period of from twenty-four to thirty hours. At the end of that time the lead monoxide will have combined with an additional quantity of oxygen, and become the red oxide. This is taken out, and, having been passed through a fine wire sieve, is packed in barrels for the purposes of commerce.

The above is an outline of the French process for making red lead. In England and the United States the calcination of the monoxide is not performed in tin boxes, but by returning it to the furnace in which it was first calcined. H. N. Warren recommends the following process for preparing pure red lead. Either litharge or lead sulphate from vitriol tanks, etc., is introduced into canvas bags, through which is inserted a lead sheet. These bags are now immersed in dilute vitriol, and connected respectively to sheets of iron; the sulphate or other plumbic compound contained therein is thus speedily and completely reduced to the spongy metal, the bags afterwards connected alternately by their lead plates and exposed to an electric current, the positives being thus completely converted into peroxide; whilst the temporary accumulator thus produced is again emptied of its current into further quantities of spongy metal, thus producing more peroxide. This process, when rightly conducted, yields an absolutely pure oxide on a cheap scale. (*Chem. News*, Sept. 18, 1896, 144.)

Properties. Red lead is in the form of a heavy, scaly powder, of a bright red color, with a slight shade of orange. Its sp. gr. is about 9. When exposed to heat it gives off oxygen, and is reduced to the state of monoxide. It is sometimes adulterated with red ferric oxide and red bole, substances which may be detected by treating the red lead with nitric acid and testing the nitric solution with tincture of galls. This reagent will produce a black precipitate, in consequence of the iron being dissolved by the nitric acid. If brick-dust be present, it will be left undissolved upon boiling the suspected specimen in water, with sugar and a small quantity of nitric acid. When free from impurities it is wholly reduced on charcoal by means of the blowpipe, giving a globule of metallic lead. It is completely soluble in highly fuming nitrous acid. When treated with nitric acid it is resolved into monoxide, which dissolves, and dioxide, which remains in the form of a dark brown powder.

The red lead of commerce may be considered as a mixture of what may be called the true red oxide and variable proportions of monoxide. That this is its nature is rendered probable by the action of cold dilute acetic acid, not used in excess, which takes up a variable quantity of monoxide, leaving a portion unchanged in color, which may be deemed the pure red oxide. This latter, when analyzed by nitric acid, has been proved, by the coincident results of Dalton, Dumas, and Phillips, to consist of three atoms of lead and four of oxygen, equal to $2PbO,PbO_2$ (Dumas), or PbO,Pb_2O_3 (Winckelblech). Mulder gives $Pb_4O_5 = 3PbO,PbO_2$, or $2PbO,Pb_2O_3$, as the usual composition of red lead.

Red lead enters into no official preparation. In the arts it is used chiefly as a paint, for protecting metal surfaces, in the manufacture of flint glass, and in cements for metal joints.

POLYFORMIN. Two kinds of polyformin are found in commerce, soluble and insoluble. The soluble form, *di-resorcin-hexa-methylene-tetramine*, $(C_6H_4(OH)_2)_2{-}(CH_2)_6N_4$, occurs in handsome colorless crystals, soluble in water and alcohol, insoluble in ether and oils, and is used as an antiferment and diuretic. Insoluble polyformin results when polyatomic phenols or such as possess condensed benzoyl-nuclei are dissolved in formaldehyde, an excess of ammonia being added subsequently; if resorcin be used, the polyformin is odorlesss, amorphous, and yellowish brown in color. The name polyformin is applied particularly to that kind which is employed as a bactericide.

POLYGALA RUBELLA. Willd. (Now recognized as *P. polygama*, Walter.) *Bitter Milkwort. Bitter Polygala. Polygale, Laitier*, Fr. *Kreutzblume, Milchwurz*, G. Bitter polygala is an indigenous, perennial plant, which was formerly official. It has a strong and permanent bitter taste, which it yields to water and alcohol. In small doses bitter polygala is tonic, in larger, laxative and diaphoretic. It appears to be closely analogous in medical virtues to *Polygala amara*, L., of Europe, which is used for a similar purpose. From the seeds of the *P. butyracea*, Heck. and Schlag., an African plant, the natives prepare an edible fat. (See *P. J. Tr.*, xx., Aug. 1889.)

POLYMNIA UVEDALIA. L. *Bear's-foot.* (Nat ord. Compositæ.) Great virtues as a remedy in *malarial splenic enlargements* have been attributed to this North American plant. (See *Newer Mat. Med.*, 53.)

POLYPODIUM. Various species of this genus of ferns are asserted to have medical properties. *Polypodium vulgare*, L., very common both in Europe and America, was believed by the ancients to be an active cholagogue purgative, and has been used in modern times as an expectorant in chronic *catarrh* and *asthma*. Dose, from one to eight drachms (3·88–31·1 Gm.), usually given with a cathartic. The rhizome, as it usually occurs in commerce, is about as thick as a goose-quill, somewhat contorted, covered with brown, easily separable scales (often wanting), furnished with slender radicles, and marked by numerous small tubercles. Its color is reddish brown with a tinge of yellow, its odor disagreeably oleaginous, its

taste peculiar, sweetish, somewhat bitter, and nauseous. *P. adiantiforme*, of Porto Rico, is believed by the natives to be a powerful antisyphilitic. It must be used freely for several months in the advanced stages of the disease. *P. friederichsthalianum*, of Central America, has similar properties attributed to it.

POLYTRICHUM JUNIPERINUM. *Haircap Moss. Robin's Rye.* This indigenous moss is stated by Wm. Wood to be a powerful diuretic, and, when given indefinitely in infusion, very useful in *dropsy*. (*Am. Journ. Med. Sci.*, N. S., xxvii. 267.) Ariel Hunter confirms these statements. (*N. J. Med. and Surg. Reporter*, ix. 417.)

PONGAMIA GLABRA. Vent. (Nat. ord. Leguminosæ.) *Pongamia* or *kurung oil* is expressed from the seeds of an East Indian tree. It is deep yellow to reddish brown, fluid at 60° F., but below that it is solid. It is especially commended in *pityriasis versicolor* and other parasitic skin diseases. (*P. J. Tr.*, February, 1883.)

POPULUS. *Poplar.* In most trees belonging to this genus the leaf-buds are covered with a resinous exudation, which has a peculiar, agreeable, balsamic odor, and a bitterish, balsamic, somewhat pungent taste. It is abundant in the buds of *Populus nigra*, L., or the *black poplar* of Europe, which are official in some parts of that continent. They contain resin and a peculiar volatile oil. The buds of *P. balsamifera*, L., growing in the northern parts of North America and Siberia, are also highly balsamic; and a resin is said to be furnished by the tree, which is sometimes, though erroneously, called *tacamahac*. The virtues of the *poplar buds* are probably analogous to those of the turpentines and balsams. They have been used in pectoral, nephritic, and rheumatic complaints, in the form of a tincture; and a liniment, made by macerating them in oil, has been applied externally in local *rheumatism*. The *unguentum populeum* of European pharmacy is made, according to the directions of the French Codex, by bruising in a marble mortar, and boiling in 2000 parts of lard, with a gentle fire, till the moisture is dissipated, 250 parts, each, of the fresh leaves of the black poppy, deadly nightshade, henbane, and black nightshade; then adding of the dried buds of the black poplar, bruised, 400 parts; digesting for twenty-four hours; straining with strong expression; and finally allowing the ointment to cool after defecation. This is an anodyne ointment, occasionally employed in Europe in painful local affections. It has been ascertained that poplar buds are capable of imparting a principle to ointments which in a powerful degree obviates their tendency to rancidity.

The bark of *P. tremuloides*, Michx., or *American aspen*, and of *P. tremula*, L., or *European aspen*, is possessed of tonic properties, and has been used in *intermittent fever*. In the bark of the latter Braconnot found *salicin*, $C_{13}H_{18}O_7$, and another crystallizable principle which he named *populin*, $C_{20}H_{22}O_8$. It is in these, probably, that the febrifuge properties of the bark reside. They may be obtained by precipitating a saturated decoction of the bark with solution of lead subacetate, filtering, precipitating the excess of lead by sulphuric acid, again filtering, evaporating, adding animal charcoal towards the end of the evaporation, and filtering the liquor while hot. Salicin gradually separates, upon the cooling of the liquor, in the form of crystals. If, when this principle has ceased to crystallize, the excess of sulphuric acid in the liquid be saturated by a concentrated solution of potassium carbonate, the populin will be precipitated. If this be pressed between folds of blotting-paper, and redissolved in boiling water, it will be deposited, upon the cooling of the liquid, in the crystalline state. The leaves of *P. tremula* are also said to yield more populin than does the bark. It is probable that both principles exist in the bark of *P. tremuloides* and other species. Schaak (*A. J. P.*, 1892, 226) found a bitter principle in the bark of *P. alba*, which was most likely populin. Salicin is described under *Salix*. *Populin* is very light, purely white, and of a bitter, sweetish taste, analogous to that of liquorice. It is soluble in 1896 parts of cold and about 70 parts of boiling water, and is more soluble in boiling alcohol. It loses its two molecules of water of crystallization at 100° C., and at 180° C. it fuses to a colorless liquid, from which at a higher temperature benzoic acid may be sublimed. Acetic acid and the diluted mineral acids dissolve it, and, upon the addition of an alkali, let it fall unchanged. Piria first showed it to be *benzoyl salicin*, $C_{13}H_{17}(C_7H_5O)O_7 + 2H_2O$. He then decomposed it and prepared salicin from it. When populin is boiled with baryta water or milk of lime, the benzoic acid precipitated by ferric chloride, the excess of iron removed by lime, and the excess of lime by carbonic acid, the remaining liquid yields salicin on evaporation. The same conversion may be effected by heating populin with an alcoholic solution of ammonia to 100° C. (212° F.). Piria obtained from populin 28·9 per per cent. of benzoic acid. (*P. J. Tr.*, xv. 378.) Dr. T. L. Phipson, basing his experiments upon the results of Piria, has succeeded in preparing populin artificially by combining salicin and benzoic acid. Nothing more is necessary than to dissolve the two substances in alcohol, and to concentrate the solution. Crystals are formed having all the characters of populin, and consisting of salicin and benzoic acid combined in the proportion of their equivalents. (*Chem. News*, Dec. 6, 1862, 278.) The flower-buds of *P. tremuloides* yielded a bitter resin to R. Glenk. It was of yellowish-brown color, strong hop-like odor, and melted at 51° C. (*A. J. P.*, 1889, 240.)

PORTULACA OLERACEA, L. *Garden Purslane.* (Nat. ord. Portulacaceæ.) This indigenous annual has been considered a cooling diuretic, and is recommended in *scurvy* and urinary affections. The seeds have been thought to be anthelmintic, but are inert.

POTASSII BISULPHAS. *Bisulphate of Potassium. Acid Sulphate of Potassium.* $KHSO_4$. "Take of Sulphate of Potash, in powder, *three ounces* [avoirdupois]; Pure Sulphuric Acid *one fluidounce* [Imperial measure]. Place the Acid and Salt in a small porcelain capsule, and to this apply a heat capable of liquefying its contents, and which should be continued until acid vapors cease to be given off. The Bisulphate, which concretes as it cools, should be reduced to a fine powder, and preserved in a well-stopped bottle." It is frequently a by-product in chemical operations, being left as residue when potassium salts are decomposed by sulphuric acid. It is a white salt, having the form of a right rhombic prism so flattened as to be tabular, and a bitter and extremely acid taste. It is soluble in twice its weight of

cold and in less than its weight of boiling water. Alcohol does not dissolve it, but, when added to an aqueous solution, precipitates the neutral sulphate. Exposed to the air, it effloresces slightly on the surface, and when moderately heated readily melts, and runs like oil. At a red heat it loses water and the excess of acid, and is reduced to a neutral sulphate. Owing to its excess of acid, it acts precisely as an acid on the carbonates, causing them to effervesce. It is incompatible with alkalies, earths, and their carbonates, with many of the metals, and with most oxides. This salt was formerly called *sal enixum*. It is an aperient. It answers, according to Dr. Barker, for preparing a cheap aperient effervescing draught. Equal weights—a drachm, for instance—of the bisulphate and of sodium carbonate may be dissolved separately, each in two fluidounces of water, then mixed, and taken in the state of effervescence. Dose, one or two drachms (3·88 or 7·77 Gm.).

POTASSII SULPHIS. *U. S.* 1880. *Sulphite of Potassium.* $K_2SO_3.2H_2O$; 193·84. $K_2SO_3.2H_2O$; 194. *Kali Sulfurosum*, *Sulfis Potassicus*, *S. Kalicus*. *Sulfite de Potasse*, Fr. *Schwefligsaures Kali*, G. *Potassium sulphite* is prepared by causing sulphurous acid to pass through a strong solution of potassium carbonate until decidedly acid; an equal weight of potassium carbonate is now added. The sulphite crystallizes out upon standing. "White, opaque, obliquely-rhombic, octahedral crystals, or a crystalline powder, somewhat deliquescent, odorless, having a bitter, saline, and sulphurous taste, and a neutral or feebly alkaline reaction. Soluble in 4 parts of water at 15° C. (59° F.) and in 5 parts of boiling water; only sparingly soluble in alcohol. When gently heated, the salt loses its water of crystallization (18·5 per cent.); at a red heat it is decomposed and leaves a residue of an alkaline reaction. The aqueous solution of the salt yields a white, crystalline precipitate on the addition of a saturated solution of bitartrate of sodium. Addition of diluted hydrochloric acid to the aqueous solution gives rise to the odor of burning sulphur, and the solution does not become cloudy (difference from hyposulphite)." *U. S.* 1880. It decrepitates when heated. In the air it effloresces, absorbing oxygen, and being partially converted into the sulphate. The occurrence of a yellow precipitate, when it is added to a solution of platinum chloride, shows that it is a salt of potassa. "A one per cent. aqueous solution of the salt, strongly acidulated with hydrochloric acid, should produce no precipitate, or, at most, only a white cloudiness, on the addition of a few drops of test-solution of chloride of barium (limit of sulphate). If 0·485 Gm. of the salt be dissolved in 25 C.c. of water, and a little gelatinized starch added, at least 45 C.c. of the volumetric solution of iodine should be required, until a permanent blue tint appears after stirring (corresponding to at least 90 per cent. of pure Sulphite of Potassium)." *U. S.* 1880.

The medical uses of this salt are essentially those of the other sulphites. It acts only as a slight laxative and diuretic. From four to six drachms (15·5–23·3 Gm.) in twenty-four hours have been given without unpleasant results. It escapes from the system with the urine, and may be found for some hours unchanged in the state of the sulphite; at the end of twenty-four hours the potassium sulphate is found in the urine instead of the sulphite, proving that the salt undergoes oxidation in the body. It was at one time much used as a germicide in bacterial diseases, but has no power over microscopic organisms in the blood, and has passed out of vogue.

The local effects of the salt are probably less doubtful than the constitutional, but even as a local remedy it is inferior to sodium sulphite and sulphurous acid. Dose, from fifteen grains to a drachm (1–3·9 Gm.), repeated so as to amount to from a fourth of an ounce to an ounce in twenty-four hours.

POTASSIO-MERCURIC IODIDE. *Mercuric Potassium Iodide. Iodohydrargyrate of Potassium.* It has been found by chemists that mercuric iodide, HgI_2, unites with the more positive metallic iodides, forming a series of double salts, sometimes called *iodohydrargyrates*. These have been particularly studied by Boullay (*Ann. Ch. Phys.* [2], 34, 345), who finds that a concentrated solution of potassium iodide will dissolve mercuric iodide in the ratio of three mols. of the mercuric salt for every two of the potassium salt. When the solution is cooled, one mol. of red mercuric iodide crystallizes out, and then from the mother-liquor deposits yellow prisms, having the composition $2(HgI_2.KI) + 3H_2O$. Clayton suggests the practical method of simply evaporating Nessler's reagent and collecting the crystals. (*Chem. News*, 1894, 102.) This is an active preparation, which may be given in the same dose and for the same purposes as corrosive sublimate. It is formed when its components are prescribed together extemporaneously. It is not decomposed by the compound syrup of sarsaparilla.

The potassium iodohydrargyrate was suggested by F. L. Winckler as a qualitative test of the organic alkaloids. F. F. Mayer subsequently employed, for volumetric analysis, a solution made with 13·546 grammes of corrosive sublimate, 49·8 grammes of potassium iodide, and a litre of distilled water. (See *Volumetric Solution of Mercuric Potassium Iodide*, U. S., PART III.) For further observations, see *A. J. P.*, 1886, 579, and 1887, 1.

POTASSIUM CHLORO-PLATINITE. Eight grains of this salt, which is used as a toning agent in photography, caused death in an infant of two months, preceded by violent gastro-enteritis and collapse. (*Brit. Med. Journ.*, i. 1896.)

POTASSIUM COBALTI-NITRITE. $Co_2(NO_2)_{12}K_6 + 2Aq$. When potassium nitrite is added to a cobalt salt solution, acidified with acetic acid, nitrogen is set free, and in course of time the double cobaltic and potassium nitrite separates as a yellowish crystalline powder, almost totally insoluble in acid solution. Wolcott Gibbs having suggested that this nitrite might be less fugacious than other nitrites, on account of its stability and relative insolubility, J. W. Roosevelt has tried it in doses of from one-quarter to one-half grain (0·016–0·032 Gm.), every two hours, in kidney cases with high arterial tension and dyspnœa, in *asthma*, and also in *cardiac valvular diseases*. He thinks that the effects of the drug are similar to those of the nitrites, beginning in fifteen minutes and lasting from two to four hours.

POTASSIUM FERRICYANIDE. *Ferridcyanide of Potassium. Red Potassium Prussiate.* $K_6Fe_2Cy_{12}$. This is formed by passing a current of chlorine through a solution of potassium ferrocyanide, until the liquid ceases to form a precipitate with a solution of ferric chloride, a proof that the

whole of the ferrocyanide has been converted into the ferricyanide. The solution, by due evaporation, yields the compound in question. It may also be prepared, in the dry way, by agitating finely powdered ferrocyanide with chlorine as long as it is absorbed. The theory of the formation of this compound is that two atoms of chlorine withdraw from two mols. of the ferrocyanide two atoms of potassium, forming potassium chloride, which remains in the mother-water, while the two atoms of iron, having assumed the ferric condition, together with the remaining potassium, saturate the cyanogen. The reaction is explained by the following equation: $2K_4Fe(CN)_6 + Cl_2 = K_6Fe_2(CN)_{12} + 2KCl$. The radical ferricyanogen is supposed to be formed by the coalescence of two mols. of ferrocyanogen, and is sometimes represented by the symbol Cfdy. This salt, discovered by Gmelin, is in beautiful deep hyacinth-red anhydrous crystals, which are soluble in four parts of water. Its solution forms a delicate test for ferrous salts, with which it produces a blue precipitate; but with ferric salts it only strikes a green or brown color. It is used in dyeing and calico-printing. (See *Test-Solutions*, PART III.)

POTASSIUM IODATE. *Iodate de Potasse*, Fr. *Kaliumjodat, Jodsaures Kali*, G. Demarquay and Custin propose the following mode of preparation, which is followed by the British Pharm. (1885) in making its test-solution. Take of iodine and potassium chlorate, each, one part, and mix them with five or six parts of water, previously acidulated with a few drops of nitric acid, and heated to ebullition. As soon as chlorine ceases to escape, treat the liquid with a concentrated solution of barium chloride. Wash with distilled water, and decompose with dilute sulphuric acid the barium iodate precipitated; filter to separate the barium sulphate, and slowly evaporate the solution. Wash with distilled water the crystals of iodic acid that are formed, dissolve them in boiling distilled water, and saturate with potassium bicarbonate. On cooling the iodate is deposited in small crystals. M. Stas prepares it by moderately heating equal mol. weights of potassium iodide and chlorate, dissolving out the chloride formed with cold water, and repeatedly crystallizing the iodate from hot water. (*A. J. P.*, 1870, 217.) M. Egidio Pollacci has found that phosphorus affords a very delicate test for the iodate, as does also the iodate for phosphorus, free iodine being liberated. (*Journ. de Pharm.*, 4e sér., xx. 104.) Demarquay and Custin assert that the potassium iodate is superior to the potassium chlorate as a local remedy in ulcerative and gangrenous *stomatitis*, *ptyalism*, *diphtheria*, and other diseases of the pharyngeal and buccal mucous membrane. Dose, from four to eight grains (0·259–0·518 Gm.). (*Dorvault's Rev. Pharm.*, 1858.)

POTASSIUM NITRITE. *Nitrite of Potassium* (KNO_2; 84·96) is most readily obtained by fusing saltpetre with lead, which withdraws one atom of oxygen from the former, changing it thereby to litharge. It is a white, fusible, and uncrystallizable mass, usually cast into sticks like the hydrate. It is very deliquescent, and absorbs carbon dioxide from the air. It shares the activities of the nitrites, producing in animals their physiological effects, and being capable of replacing them in the treatment of disease. Its influence is comparatively slow and permanent. Five grains have produced mild poisoning. Dose, three grains (0·194 Gm.).

POTASSIUM PERCHLORATE. *Hyperchlorate of Potassium.* $KClO_4$. This salt is prepared by fusing potassium chlorate until it begins to assume a pasty condition. The cooled mass consists of potassium perchlorate and chloride. The absence of undecomposed chlorate may be known by a sample failing to communicate a yellow color to hydrochloric acid. The mass must be dissolved in the smallest possible quantity of boiling water, when perchlorate crystallizes out. It is sparingly soluble in water, and insoluble in alcohol. Its effects are wholly different from those of potassium chlorate, and it has been commended in *intermittents*. (*Ann. de Thérap.*, 1869, 141.)

POTASSIUM PHOSPHATE. *Phosphate of Potassium.* K_2HPO_4. The potassium phosphate which has come into use as a medicine is the *dipotassic orthophosphate*, having a composition precisely analogous to that of the medicinal sodium and ammonium phosphates. It may be formed precisely as sodium phosphate is prepared; or by saturating, by means of potassium carbonate, common or ortho-phosphoric acid, H_3PO_4. The medicinal potassium phosphate is a white, amorphous, deliquescent salt, crystallizing with difficulty. It has been given as an alterative in *scrofula* and *phthisis* with supposed advantage. The dose is from ten to thirty grains (0·648–1·94 Gm.), three times a day, dissolved in a teaspoonful of water.

POTASSIUM SILICATE. *Silicate of Potassium*, K_2SiO_3, also known as *soluble glass*, is prepared in the same way as the sodium salt. These salts have been used in *rheumatism*, *gout*, etc. (*A. J. P.*, 1857, 314; *Ann. de Thérap.*, 1865, 236), but are probably of no service. They form excellent substitutes for starch, dextrin, and plaster of Paris in the preparation of immovable surgical dressings. The solution is applied, of a syrupy consistence, by means of a brush, to the bandages, upon which it rapidly hardens, requiring only five or six hours for this result. The facility of removing them by means of hot water is another advantage which it possesses over other dressings. (*Journ. de Pharm.*, 4e sér., iv.)

POTASSIUM SULPHOCYANATE. CNKS. *Sulfocyanure de Potassium*, Fr. *Kalium Sulfocyanat, Rhodankalium*, G. Potassium sulphocyanate, formerly called potassium sulphocyan*ide*, is prepared by fusing in an iron vessel, at a low red heat, a mixture of two parts of dried potassium ferrocyanide and one part of flowers of sulphur. The mass, when cold, is dissolved in boiling water; and, to decompose some ferric sulphocyanate, the solution is treated with potassium carbonate, which throws down the iron as a carbonate, and gives rise to the formation of a fresh portion of potassium sulphocyanate. The whole is then boiled for a quarter of an hour, filtered to separate the precipitated iron, and evaporated that crystals may form. These are purified from potassium carbonate by being dissolved in alcohol, which takes up the sulphocyanate and leaves the carbonate. The alcoholic solution is then allowed to crystallize. Potassium sulphocyanate is in long, striated, anhydrous prisms, deliquescent in a moist atmosphere, very soluble in alcohol, and having a cooling, somewhat biting taste. It has been proposed by Sömmering as a substitute for hydrocyanic acid and potassium cyanide, on the ground that it possesses

the same therapeutic properties without their inconveniences.

POTENTILLA. *Potentilla reptans*, L., the *cinquefoil* of Europe, and *Potentilla canadensis*, L., the cinquefoil of America (nat. ord. Rosaceæ), have each been used as astringents in *diarrhœa*, *chronic catarrhs*, *night-sweats*, etc., taken *ad libitum*.

POWDER OF ALGAROTH. *Pulvis Algarothi. Oxychloride of Antimony. Nitro-muriatic Oxide of Antimony.* A powder rarely used now. For a description of its uses, properties, etc., see 14th edition *U. S. Dispensatory*.

PRASOID. A solution, of which one hundred drops contain 0·135 Gm. of globularin and 0·153 Gm. of globularetin. It is used in *gout* and *rheumatism* in doses of from fifteen to twenty drops, three times daily.

PRINOS. *Black Alder. Winterberry. Feverbush. Prinos*, Fr., G. The U. S. P. formerly recognized the bark of the *Prinos verticillatus*, Linn. (now *Ilex verticellata*, A. Gray, also (L.) A. Gray). (Nat. ord. Ilicaceæ.) It is a shrub from six to twenty-five feet high, furnished with alternate, spreading branches, and covered with a bluish-gray bark. The leaves are alternate, on short petioles, oval, pointed, tapering at the base, acutely serrate, of a dark green color, smooth above, but downy on the veins beneath. The flowers in cymes; the staminate from two- to ten-flowered; the pistillate being from one- to three-flowered; pedicels two-bracted; calyx lobes obtuse, ciliate persistent; the ovary large, green, and roundish, with a short style, terminating in an obtuse stigma. The fruit when ripe consists of glossy, scarlet, roundish berries, about the size of a pea, containing six cells and six seeds. Several of these berries are clustered, so as to form little bunches at irregular intervals on the stem. It grows in the United States from Canada to Florida, and west to Missouri and Wisconsin, frequenting low wet places, such as swamps, and the borders of ponds, ditches, and streams. Its flowers appear in June. The berries, which have a bitter, sweetish, somewhat acrid taste, are sometimes used medicinally for the same purposes with the bark. The dried bark was officially described as in "thin, slender fragments, about one-twenty-fifth of an inch (1 Mm.) thick, fragile, outer surface brownish ash-colored, with whitish patches and blackish dots and lines, the corky layer easily separating from the green tissue; inner surface pale greenish or yellowish; fracture short, tangentially striate; nearly inodorous, bitter, slightly astringent." *U. S.* 1880. It has no smell, but a bitter and slightly astringent taste. Boiling water extracts its virtues. Mr. Wm. J. Lerch failed to find berberine in it. (*A. J. P.*, 1873, 251.)

Black alder has been considered tonic and astringent, and has been used in *diarrhœa* and as a substitute for Peruvian bark, but has no antiperiodic properties. In cases of flabby or ill-conditioned *ulcers* it is popularly used both locally and internally in decoction (two ounces in three pints of water boiled to a quart). Dose, from two to three fluidounces (60–90 C.c.).

PRIORIA COPAIFERA. Griseb. (Nat. ord. Leguminosæ.) The *oil-tree* is a native of the West Indies, where it attains the height of eighty feet, and yields an exudate which is known as the *gum of the oil-tree*. This is a thick adhesive liquid, resembling copaiba, usually turbid on account of a greenish substance, which, however, finally subsides, leaving a clear, brownish-yellow liquid. For chemical study, see *A. J. P.*, Jan. 1898.

PROPIONE. *Di-ethyl-ketone.* $C_2H_5.CO.C_2H_5$. (Corresponding to Acetone or Di-methyl-ketone.) A mobile, easily soluble liquid, boiling at 101° C. Dose, as an hypnotic, from eight to forty-five grains (0·5–3 Gm.).

PROTEA MELLIFICA. *Sugar-bush.* A plant growing in South Africa, from the leaves of which Merring Beck in 1886 obtained *proteacin*. Merck and Hesse subsequently named the principle *leucodrin*. Hesse found the leaves to yield from 2 to 5 per cent. of *hydroquinone* associated with *proteacic acid*. (*P. J. Tr.*, 1896, 426.)

PRUNELLA VULGARIS. L. *Self-heal. Heal-all. Brunella vulgaris. Páquerette*, Fr. *Braunelle, Braunheil*, G. A small perennial labiate herb, which is common both in Europe and the United States. It was formerly used in *hemorrhages* and *diarrhœa*, and as a gargle in *sore throat*.

PSIDIUM POMIFERUM. Prof. Hartwich examined the root, bark, and leaves of this plant from India. (See *Pharm. Rev.*, 1896, 257.)

PSORALEA. Of this genus (nat. ord. Leguminosæ) various species are useful. *Ps. castorea*, S. Wats., *Ps. mephitica*, S. Wats., and especially *Ps. esculenta*, Pursh, are all employed by the Indians of the Northwestern United States, and by the settlers, as articles of food, *Ps. esculenta* being the *prairie turnip* or *prairie potato*, the *tipsinah* and *taahgu* of the Indians. Mr. C. Richardson found in it nearly 70 per cent. of starch, and 5 per cent. of a new, rapidly crystallizing sugar, which has not been further investigated. *Ps. glandulosa, culen, yolochiahitl*, of the Mexican Pharmacopœia, yields a leaf which is used as a tonic or anthelmintic, and an emetic root. *Ps. bituminosa*, of Europe, and *Ps. physodes*, of California, are popularly considered tonic and emmenagogue, whilst *Ps. eglandulosa* (Elliot) (*Ps. melilotoides*, Michaux, *Congo root, Bob's root, Samson's snakeroot*), of Virginia, has been recommended as an aromatic bitter tonic, especially useful in *chronic diarrhœa*. The part employed is the root, from which Mr. MacNair obtained about 2 per cent. of a volatile oil, having the specific gravity 0·93, a pungent and bitterish taste, and a neutral reaction; also a bitter principle, but not tannin. For further description, see *A. J. P.*, July, 1889; also fourteenth and sixteenth editions of *U. S. D. Ps. corylifolia*, of India, yields an oleoresin which is used in the treatment of *leucoderma* and other skin diseases. (*P. J. Tr.*, Sept. 1881.)

PTELEA TRIFOLIATA. L. *Wafer-ash. Wing-seed. Shrubby Trefoil. Hop-tree. Orme à trois feuilles*, Fr. *Hopfenbaum, Kleebaum*, G. (Nat. ord. Rutaceæ.) This is a shrub, six or eight feet in height, growing in rocky places from Long Island to Florida and west to Texas and Minnesota. The root-bark, dried, occurs in cylindrical rolls or quills, one or two lines in diameter and from one to several inches long, of a light brownish color, irregularly wrinkled, and covered with a thin epidermis. Internally it is yellowish white, but darkens by exposure. It has a peculiar somewhat aromatic smell, and a bitter, persistently pungent, and slightly acrid, yet not disagreeable taste. It yields its virtues to water, but more readily to alcohol. Steer found it to contain an oleoresin of an acrid and bitter taste. He also extracted

from it the alkaloid *berberine*, which is probably the tonic principle, while the oleoresin may impart to the bark somewhat stimulant properties. (*A. J. P.*, 1867, 337. See also *Ibid.*, 1862, 198.) It is said to have been much employed among the physicians of the Western States in the treatment of *dyspepsia*, and generally in diseases requiring a mild, non-irritating, bitter tonic.

PTOMAINES. Within the past few years a class of very interesting compounds have been described and are known under this name. They are alkaloid-like bases obtained from animal tissue after decomposition has commenced, hence sometimes called *cadaveric alkaloids*. Bence Jones and Dupré (*Pharm. Centralhalle*, 16, No. 10) first published a notice of the finding of an alkaloid-like base from a decomposing human liver. Its sulphate solution fluoresced, and in other ways resembled quinine, yielding precipitates also with the usual alkaloidal reagents, potassio-mercuric iodide, phosphomolybdic acid, and gold and platinic chlorides. It appears, however, that Marquardt had isolated such bases even previous to this. The chief investigators of this class of alkaloids have been Selmi, who first systematically studied them and gave them the name ptomaines, and Brieger, who since 1882 has published a series of elaborate studies and has classified their reactions. From cadavers which had been buried one, three, six, and ten months, in different cases, Selmi obtained bases of strongly alkaline reaction, all of which formed characteristic crystalline compounds with a solution of hydrogen iodide containing dissolved iodine. Three were soluble in ether, but not poisonous; one, insoluble in ether but soluble in amyl alcohol, was in the highest degree poisonous, producing in rabbits tetanus, strong dilatation of the pupil, paralysis of the heart, and death. All of these bodies give the general alkaloid reactions, but change rapidly when exposed to the air. Brieger's researches established the additional fact that ptomaines are formed during the earlier stages of decay, and that they are in general of a non-benzenoid character, but that as putrefaction continues they gradually disappear and give place to well-known benzenoid compounds, phenol, cresol, indol, etc. Brieger studied the ptomaines from (*a*) putrid horse flesh, beef, and human muscular tissue; (*b*) from putrid fish; (*c*) from putrid cheese; (*d*) from putrid glue; and (*e*) from putrid yeast. The bases obtained are of two classes. At first are obtained oxygenated bases, like *choline*, $C_5H_{15}NO_2$, *muscarine*, $C_5H_{15}NO_3$, *neurine*, $C_5H_{13}NO$, *gadinine*, $C_7H_{18}NO_2$, and *tetanine*, $C_{13}H_{20}N_2O_4$. These seem later to disappear, and amines seem to be almost the only products. Among these mentioned, the simplest are *dimethylamine*, $(CH_3)_2NH$, *trimethylamine*, $(CH_3)_3N$, and *triethylamine*, $(C_2H_5)_3N$. A number of the others seem to be diamines, like *putrescine*, $C_4H_{12}N_2$, *cadaverine*, $C_5H_{14}N_2$, *saprine*, $C_5H_{16}N_2$, *neuridine*, $C_5H_{14}N_2$, all four discovered by Brieger in the cadaver, *collidine*, $C_8H_{11}N$, *hydrocollidine*, $C_{11}H_{13}N$, *parvoline*, $C_9H_{13}N$, and *tyrotoxicon* (*diazobenzene*), $C_6H_5N_2$, discovered by Vaughan in poisonous cheese and in ice-cream.

The formation of these volatile and frequently actively poisonous bases in the cadaver would seem to make the task of the toxicologist very difficult when the search for poisonous bases has been delayed until decomposition has set in. Any reagent or reagents, therefore, which will enable the chemist to decide between vegetable bases and these ptomaines becomes very important. Brouardel and Bontury (*Comptes-Rendus*, 92, 1056) state that they have found such a decisive reagent in potassium ferricyanide. This compound when treated with a solution of a pure vegetable alkaloid is unacted upon by it; while, under the same conditions, it is instantly reduced to the state of ferrocyanide by a ptomaine, and thus becomes capable of forming Prussian blue with a ferric salt. Up to the present but two exceptions to this rule have been found,—morphine, which readily reduces potassium ferricyanide, and veratrine, which gives traces of such reduction. It is possible, however, that in this last case the reducing action is due to certain impurities which the investigators were unable to remove completely from the veratrine employed by them.

Ptomaines are probably devoid of medical properties, but are of great interest to the toxicologist, not only from a chemical stand-point, but also from the fact that they are excessively fatal in their effects upon the animal economy. The well-known action of putrefactive flesh, the curious poisonings sometimes produced by lobsters and other animals which feed upon carrion, are in all probability caused by them. In regard to treatment of poisoning by putrefactive animal matters, our present knowledge only justifies the immediate evacuation of the stomach and bowels and the meeting of the various indications as they arise. For fuller information as to the formation of ptomaines, their detection, separation, and clinical features, see *Ptomaines and other Animal Alkaloids*, by A. C. Farquharson, M.D. Bristol: John Wright & Co., 1892.

PULMONARIA OFFICINALIS. L. *Lungwort. Pulmonaire*, Fr. *Lungenkraut*, G. (Nat. ord. Boraginaceæ.) An herbaceous perennial, European plant, sometimes cultivated. The leaves have been employed in *catarrh*, *hæmoptysis*, and *consumption*, but their virtues are doubtful.

PUMICE STONE. *Pumex. Obsidian.* A very light porous stone, found in the vicinity of active and extinct volcanoes, and believed to have been thrown up during their eruption. The spongy structure of pumice is believed to be due to the effects of aqueous vapor upon lava whilst in a fluid state. The pumice stone of commerce is said to be obtained chiefly from Lipari. It is used whole, in the manner of a file, for removing the outer surfaces of bodies, or for rubbing down inequalities, and, in the state of powder, for polishing glass, metals, stones, etc.; purposes to which it is adapted by the hardness of its particles. (See *P. J. Tr.*, 1882.)

PUNEERIA COAGULANS. Stocks. (Now *Withania coagulans*, Dun.) *Vegetable Rennet.* (Nat. ord. Solanaceæ.) This shrub, common in Afghanistan and Northern India, has the property of coagulating milk, and has been used for making a vegetable rennet ferment for making cheese. Sheridan Lea found upon examination that the substance which possesses the coagulating power is a ferment closely resembling animal rennet. The active principle is soluble in glycerin, and can be extracted from the seeds by this means; the extract possesses strong coagulating powers even in small amounts. Alcohol precipitates the ferment body from its solutions; and the precipitate, after washing with alcohol, may be dissolved again without having lost its coagulating powers. The active principle of the seeds will cause the coagulation of milk when present in very small quantities, the

addition of more of the ferment simply increasing the rapidity of the change. The coagulation is not due to the formation of acid by the ferment. If some of the active extract be made neutral or alkaline, and added to neutral milk, a normal clot is formed, and the reaction of the clot remains neutral or faintly alkaline. The clot formed by the action of the ferment is a true clot, resembling in appearance and properties that formed by animal rennet, and is not a mere precipitate. Lea prepared an active extract applicable for cheese-making purposes, by grinding the dry seeds very finely in a mill, and extracting them for twenty-four hours with such a volume of 5 per cent. sodium chloride solution that the mass is still fluid after the absorption of water by the fragments of the seeds as they swell up. From this mass the fluid part may be readily separated by using a centrifugal machine (such as is used in sugar refining), and it can then be easily filtered through filter-paper; without the centrifugal machine the separation of the fluid from the residue of the seeds is tedious and imperfect; forty grammes of the seeds treated as above, with 150 C.c. of 5 per cent. sodium chloride solution, gave an extract of which 0·25 C.c. clotted 20 C.c. of milk in twenty-five minutes, and 0·1 C.c. clotted a similar portion of milk in one hour. When added in these proportions the curd formed is quite white. The presence of the coloring matter is, however, perhaps on the whole unimportant, since even if a larger quantity of the ferment extract is added in order to obtain a very rapid coagulation, the coloring matter is obtained chiefly in the whey, the curd being white; by adding sufficient common salt to make the percentage up to 15 per cent., and alcohol up to 4 per cent., the preparation would retain its activity very well. (*P. J. Tr.*, 1884, 606.)

PURAL. Powdered wood charcoal is saturated with a mixture of menthol and carbolic and benzoic acids, and compressed into cylinders. The latter when dried are ignited by a flame and used for disinfecting rooms.

PYCNANTHEMUM LINIFOLIUM. Pursh. (*Origanum flexulosum*, Walt.; *Kœllia flexulosa* (Walt.), MacM.) *Dysentery Weed.* This American mint is popularly used in bowel complaints; its hot infusion is diaphoretic. (See *A. J. P.*, 1894, 65, 169; *Pharm. Rund.*, 1896, 32.)

PYRAMIDON. *Di-methyl-amido-phenyl-dimethyl-pyrazolon.* This is a derivative of antipyrin in which an H atom of the pyrazolon group is replaced by a dimethyl-amido group. It is said to be formed by reducing iso-nitroso-antipyrin and methylating the product so obtained. Pyramidon is a yellowish-white crystalline powder, soluble in water to the extent of 1 in 10 (maximum of solubility is reached at 80° C.), and practically tasteless. Pyramidon may be easily distinguished from antipyrin by its color reactions with various reagents. Ferric chloride gives a deep blue-violet fugitive color, and not the red of antipyrin. Nitrous acid gives a fugitive violet instead of the more permanent green of iso-nitroso-antipyrin. Nitric acid also gives a violet to amethyst coloration. In the urine pyramidon may best be detected by ferric chloride, although the color produced is no longer a pure blue, but Tokay red with a tinge of amethyst. Filehne (*Berl. Klin. Woch.*, 1896) states that pyramidon resembles in its action antipyrin, and is equally efficient as an antipyretic and analgesic, but affirms that it is much more active and that its effects are more lasting than those of antipyrin. The statements of Filehne are confirmed by Horneffer (*Berl. Klin. Wochensch.*, xxxiv. 1897), who further says that he has given it daily for two months without any disagreeable results. The dose, from five to twenty grains (0·3–1·3 Gm.), may be repeated every three or four hours, not exceeding forty grains in the twenty-four hours, administered in capsule or in aromatic solution.

PYRANTIN. *P-ethoxyphenylsuccinimide. Phenosuccin.* $\begin{matrix}CH_2—CO\\ \\ CH_2—CO\end{matrix}\!\!>\!N—C_6H_4—OC_2H_5$. It is prepared by melting together *p*-amidophenetol hydrochloride or phenacetin with succinic acid and extracting with alcohol. It is colorless, crystallizes in needles melting at 155° C., is insoluble in ether, but soluble in 83·6 parts of boiling water and in 1317 parts of water at 17° C. Alkalies convert it into salts of *p*-ethoxyphenylsuccinamic acid, which are soluble in water. A. Piutti states that this drug possesses properties analogous to phenacetin. Renzi and De Govanni have found it especially useful in acute *rheumatism* in doses of from fifteen to forty-six grains (0·97–3 Gm.) per day. It is said to have no action on the cardiac, respiratory, or digestive organs. (*Chem. Zeit.*, xx.)

PYRAZOLE. $C_3H_4N_2$. $\left(\begin{matrix}CH=N\\ |\\ CH=CH\end{matrix}\!\!>\!NH\right)$. This compound has been prepared by acting upon epichlorhydrin with hydrazine in the presence of zinc chloride. It is a basic substance, crystallizing in needles, melting at 70° C., and boiling at 188° C. It is readily soluble in water, alcohol, and ether. All of the pyrazole derivatives were found by Tappeiner (*Archiv Exper. Pathol.*, 1891) to act as paralyzants of the central nervous system. Only one of them, *phenylmethylpyrazolcarboxylic acid*, seems to promise value in practical medicine, on account of its extraordinary active diuretic effects upon both the lower animals and man. Daily dose, from fifteen to thirty grains (0·972–1·94 Gm.). No disagreeable symptoms have been observed.

PYRETHRUM PARTHENIUM. Sm. *Matricaria Parthenium.* Linn. (Now recognized as *Chrysanthemum Parthenium.* Bernh.) *Feverfew. Matricaire*, Fr. *Mutterkraut*, G. (Nat. ord. Compositæ.) A perennial herbaceous plant, about two feet high, with an erect, branching stem, pinnate leaves, oblong, obtuse, gashed, and dentate leaflets, and compound flowers in a corymb upon branching peduncles. It is a native of Europe, but cultivated in our gardens. The whole herbaceous part is used. The plant has an odor and taste analogous to those of chamomile, which it resembles also in the appearance of its flowers and in its medical virtues. According to Zeller, a pound of it yields 4·8 grains of volatile oil. (*Centralblatt*, 1855, 205.) The volatile oil is greenish, boils between 165° C. (329° F.) and 220° C. (428° F.), and separates on standing. *Pyrethrum camphor*, $C_{10}H_{16}O$, contains in addition a hydrocarbon and an oxidized oil. (Dessaignes and Chautard, *Journ. de Pharm.* (3), 13, 241.) Though little employed, it is undoubtedly possessed of useful tonic properties. The flowers of this and of a closely resembling species, *Matricaria parthenoides* (Desf.), are said to be used in France, to a considerable ex-

tent, indiscriminately with those of the true chamomile plant, *Anthemis nobilis*, which they closely resemble, especially when double. They may, however, be distinguished, in this state, by their peculiar odor, their smaller receptacle, which is, moreover, rounded and flattened above, instead of being conical and somewhat pointed as in the Anthemis, and by the tubular five-toothed central florets, which in the chamomile are small, few, and scarcely visible, but, in the two species of Pyrethrum, are large, very numerous, and very long.

PYRIDINE. C_5H_5N. Pyridine is the first of a series of homologous bases which are found in coal-tar naphtha, in shale-oil, in peat-tar, in tobacco-smoke, and more especially in the product known as *Dippel's oil*, obtained by the distillation of bones and other animal matter. It has been used as an antiseptic and germicide, and is employed in Germany for "denaturating" alcohol for manufacturing uses. Pure pyridine is a colorless liquid, with a powerful and persistent odor, of sp. gr. 0·9858 at 0° C., and boils at 115° C. It is miscible with water in all proportions, but is precipitated from its solution by excess of strong soda or potash. It is also miscible with alcohol, ether, chloroform, benzene, and fatty oils. In toxic dose pyridine is a violent poison, producing cyanosis, methæmoglobinization of the blood, great muscular weakness from paralysis both of the motor centres and nerves, and finally death from failure of respiration. De Renzi asserts that in small doses it stimulates the heart, increases the blood-pressure, and is a useful remedy in angina pectoris. It was first introduced into practical medicine, as a remedy for *asthma*, by Germain Sée, whose statement has since been confirmed by various clinicians. Sée employed it by exposing about a drachm upon a plate in a small room, in which the patient remained from twenty to thirty minutes, the process being repeated several times a day; or from five to twenty drops in two ounces of water may be taken by an atomizer; or five drops may be inhaled directly. De Renzi has given it internally in the daily dose of six drops gradually increased to twenty-five.

PYRIDINE TRICARBOXYLIC ACID. $C_5H_2(COOH)_3N$. This important derivative of pyridine may be prepared by the oxidation of methyl-pyridine (picoline), or is obtained from certain natural alkaloids, such as quinine, quinidine, and cinchonidine, by boiling with an alkaline solution of potassium permanganate. It forms prisms melting at 244° C. This substance is said to be an active antiseptic and antipyretic, and, according to Dr. Rademaker, in *malarial fever* even surpasses quinine, when given in dose of ten grains (0·648 Gm.) after the paroxysm. The same authority asserts that, when given in doses of from one to two grains (0·06–0·13 Gm.), it will arrest the paroxysm of spasmodic *asthma*. It has also been used in *typhoid fever* as an antipyretic, and as a specific in *gonorrhœa*, when it is given by injection. (*Medical Herald*, June, 1887, 1888.) No accidents have been reported from its use.

PYROSAL. *Antipyrin salicyl-acetate*, introduced by J. D. Riedel, occurs as colorless crystals, of an acidulous taste and difficultly soluble in water. It contains 50 per cent. of antipyrin and 37 per cent. of salicylic acid, and has been used in *polyarthritis*, severe *influenza*, *febrile cystitis*, *migraine*, and *sciatica*, in doses of from eight to fifteen grains (0·51–0 9 Gm.), from two to six times daily.

QUINA MORADA. This drug, growing in Bolivia and the Argentine Republic, and there credited with the therapeutic values of cinchona, is produced by the *Pogonopus febrifugus* (nat. ord. Rubiaceæ). It has been studied by Arata and Canzoneri, who find in it a blue fluorescent substance, *moradin*, and an alkaloid, *moradeine*. (*P. J. Tr.*, April, 1890.)

QUINACETINE SULPHATE. $(C_{27}H_{31}N_3O_2)_2H_2SO_4.H_2O$. This is obtained by the reaction of certain organic compounds with methoxylated ditetrahydro-chinolyl. It is a colorless, odorless, and tasteless powder, and dissolves readily in acidulated water. It is antipyretic and anodyne.

QUINOA. The *Chenopodium quinoa*, Willd. (nat. ord. Chenopodiaceæ), is largely cultivated in Southern Peru and Southern Chili, often above the height at which barley and rye will ripen, for the sake of its seeds. These are about the size of white mustard-seeds, but flatter, and afford a flour resembling somewhat oatmeal. The starch grains are very small, and constitute about 40 per cent. of the grain, which also contains 5 per cent. of sugar, 7½ of casein, and 11 of albumen and other protein compounds. One variety, the red quinoa, contains a bitter principle in the seed-husks, and is used to some extent as an emetic and antiperiodic. (*A. J. P.*, 1872, 559.)

RAISINS. *Uva Passa.* U. S. 1870. The dried ripe fruit of the *Vitis vinifera*, L. (nat. ord. Vitaceæ), are no longer recognized by the Pharmacopœia. The grape-vine itself is too well known to require description. Its leaves and tendrils are somewhat astringent, and were formerly used in *diarrhœa*, *hemorrhages*, and other morbid discharges. The juice which flows from the stem was also thought to be possessed of medicinal virtues, and the idea still lingers among the vulgar in some countries. The unripe fruit has a harsh sour taste, and yields by expression a very acid liquor, called *verjuice*, which was much esteemed by the ancients as a refreshing drink when diluted with water. It contains malic and tartaric acids, and an acid called *racemic acid*, a compound isomeric with tartaric acid, but differing from it in being optically inactive. M. A. Petit has ascertained that grape-leaves contain 2 or 3 per cent. of glucose, and a quantity of acid varying from 1·3 to 1·6 per cent. Of the acid, tartaric acid constituted one-third, and most of this was in the form of cream of tartar. In a subsequent investigation, Petit found that, besides glucose, or sugar of grapes, the leaves contained a notable portion of common or cane sugar. In one instance he got 0·97 per cent. of cane sugar and 2·655 of glucose; in another, in which he operated so that the common sugar in the leaves had less opportunity to be converted into glucose, he got 1·58 per cent. of the former and 1·749 of the latter. (*Journ. de Pharm.*, Janv. 1874, 41.) The seeds afford from 15 to 18 per cent. of a bland fixed oil, which is occasionally extracted. Fitz (*Ber. Chem. Ges.*, 1871, 442) has shown that it consists of the glycerides of *erucic acid*, $C_{22}H_{42}O_2$, stearic and palmitic acids, the first-named acid largely prevailing. The seeds further contained from 5 to 6 per cent. of tannic acid, which also exists in the skin of the fruit. The grape, when quite ripe, is among the most pleasant and grateful fruits brought upon the table, and is admirably adapted,

by its refreshing properties, to febrile complaints. If largely taken, it proves diuretic and gently laxative. The ripe fruit differs from the unripe in containing more sugar and less acid, though never entirely destitute of the latter. The plant is supposed to have been derived originally from Asia; but it has been cultivated in Europe and Northern Africa from the remotest antiquity, and is now spread over all the temperate civilized regions of the globe. The fruit is exceedingly influenced by soil and climate, and the varieties of the plant which have resulted from culture or situation are innumerable. Those which yield the raisins of commerce are confined to the basin of the Mediterranean.

Several varieties of raisins are known in commerce. The best of the European fruit are the *Malaga raisins*, imported from Spain. They are large and fleshy, of a purplish-brown color and sweet agreeable taste. Those produced in Calabria are similar. The *Smyrna raisins* are also large, but of a yellowish-brown color, slightly musky odor, and less agreeable flavor. They are originally brought from the coast of Syria. The *Corinthian raisins*, or *currants* as they are commonly called in this country, are small, bluish black, of a fatty appearance, with a vinous odor, and a sweet, slightly tartish taste. Their name is derived from the city in the vicinity of which they were formerly cultivated. At present they are procured chiefly from Zante, Cephalonia, and the other Ionian Islands. In the older Pharmacopœias they are distinguished by the title of *uvæ passæ minores*. Within the last few years the production of raisins in California has become an industry of the highest importance. According to the report of Mr. De Barth Shorb, the raisin product of California in 1890 was 41,000,000 lbs.; in 1891, 50,000,000 lbs.; in 1892, 62,000,000 lbs. Raisins contain a larger proportion of sugar than do recent grapes. This principle, indeed, is often so abundant that it effloresces on the surface or concretes in separate masses within the substance of the raisin. The average composition of the raisin is given as 32·02 per cent. water, 2·42 nitrogenous material, 0·59 fat, 54·56 sugar, 7·48 other nitrogenous organic matter, 1·72 wood-fibre, and 1·21 ash. (König, *Nahrungs- und Genussmittel*, 3te Aufl., ii. 815.) The *sugar of grapes* (*glucose*) differs from that of the cane, being less sweet, less soluble in cold water and much less so in alcohol, and forming a syrup of less consistence.

The chief medical use of raisins is to flavor demulcent beverages. Taken in substance they are gently laxative, but are also flatulent and difficult of digestion, and, when largely eaten, sometimes produce unpleasant effects, especially in children.

RANDIA DUMETORUM. Lam. (Nat. ord. Rubiaceæ.) The fruit of this East India shrub is used by the natives as a fish-poison, and is said to act in man as an irritating emetic. According to the *Pharmacographia Indica*, each fruit contains about four grains of saponin, besides valerianic acid. The tincture has been used by Sir James Sawyer (*London Lancet*, 1891) as an antispasmodic.

RANUNCULUS. *Crowfoot. Renoncule*, Fr. *Hahnenfuss*, G. Most of the plants belonging to the genus Ranunculus have similar acrid properties, and, from their close resemblance, are confounded under the common name of *buttercup*. *R bulbosus*, L., was formerly on the Secondary List of the U. S. Pharmacopœia; but *R. sceleratus*, L., had attracted more attention in Europe, and *R. acris*, L., and *R. flammula*, L., were recognized by the Dublin College. In all these species the plant itself is a violent irritant, producing when chewed excessive inflammation in the mouth and throat, and when swallowed toxic gastritis which may be fatal. The acrid principle appears to be volatile; according to Dr. Bigelow, it is yielded to water in distillation. Dr. Clarus discovered, in *R. sceleratus*, L., besides the acrid volatile oil, a nearly inert resin, and a narcotic principle called *anemonin* or *anemone camphor*, $C_{15}H_{12}O_6$. The volatile oil is soluble in ether, and is decomposed, on standing, into a white amorphous substance having acid properties (*anemonic acid*), $C_{15}H_{14}O_7$, and into anemonin. (*Brit. and For. Med.-Chir. Rev.*, 1859, 181.) Rochebrune states that he has separated from *R. aquatilis*, L., *R. flammula*, L., *R. sceleratus*, L., and *R. bulbosus*, L., crystalline alkaloids to which he has given the name of *ranunculine*, although their identity is doubtful. These alkaloids are violent irritants and active cardiac poisons. (*Toxicol. Africaine*, i.) Before the introduction of cantharides the green buttercup plants were much employed as vesicants.

REALGAR. As_2S_2. *Red Orpiment.* This is *arsenic disulphide*. It is found native in Saxony, Bohemia, Transylvania, and in various volcanic regions. Realgar is artificially made by melting arsenous acid with about half its weight of sulphur. Thus prepared, it is of a crystalline texture, of a beautiful ruby-red color, of a uniform conchoidal fracture, somewhat transparent in thin layers, and capable of being sublimed without change. Native realgar is said to be innocent when taken internally, while that artificially prepared is poisonous, in consequence, according to Guibourt, of containing a little free arsenous acid. Realgar is used only as a pigment.

RED CHALK. *Reddle.* A mineral substance of a deep red color, of a compact texture, dry to the touch, adhering to the tongue, about as hard as chalk, soiling the fingers when handled, and leaving a lively red trace when drawn over paper. It consists of clay and ferric oxide, and is intermediate between *bole* and *red ochre*, containing more ferric oxide than the former and less than the latter. It is used for drawing lines upon wood, etc., and is sometimes made into crayons by levigating and elutriating it, then forming it into a paste with mucilage of gum arabic, moulding this into cylinders, and drying it in the shade. It has been used internally as an absorbent and astringent.

REGIANINE. This is a principle obtained by Phipson from the nut of *Juglans regia*. It occurs in octahedral, prismatic, or feathery crystals, and gives with ammonia and other alkalies a reddish-purple solution, from which hydrochloric acid precipitates an amorphous powder, *regianic acid*. It is probably identical with the *nucin* obtained from green walnut-shells.

RENNET. *Gastric Juice. Liquor Seriparus. Laabessenz*, G. For a full account of the constitution of gastric juice and its properties the reader is referred to works upon physiology. The crude juice was applied by Dr. P. S. Physick to foul ulcers. *Rennet* is an aqueous or vinous infusion of the dried stomach of the calf, though that of the sheep or other animal would probably answer the same purpose. It is much used, as every one knows, for curdling milk; a property which it

owes to a portion of the gastric secretion, retained and dried in the mucous tissue of the stomach. To the same material it probably owes the property which it possesses of converting glucose into lactic acid; and there is little doubt that it is capable, in greater or less degree, of exercising the solvent property of gastric juice over albuminous and fibrinous food. It is highly probable that the preparation usually employed to curdle milk may contribute to the ready digestibility of the curds and whey. George Ellis prepares *rennet-wine* as follows. Take the stomach of a calf immediately after death, cut off and reject about three inches of the upper or cardiac portion, slit the stomach logitudinally, wipe it gently with a dry napkin so as to remove as little of the clean mucus as possible, then cut it into small pieces, the smaller the better, put it into a common wine-bottle, fill the bottle with good sherry, and let it stand corked for three weeks. The dose is a teaspoonful, in a wineglassful of water, immediately after each meal. It is known to be good if a teaspoonful will coagulate half a pint of milk in two minutes at 100° F.

RESALGIN. *Resorcylalgin.* This occurs in crystalline needles soluble in 150 parts of cold water and 20 parts of boiling water, readily soluble in alcohol, ether, and chloroform. It is obtained by acting on antipyrin with potassium resorcylate. Forms colorless, odorless crystals, melting at 110·5° C.

RESEDA LUTEOLA. L. *Weld. Dyer's Weed. Herbe Jaune, Gaude,* Fr. *Wau, Gelbkraut, Harnkraut,* G. (Nat. ord. Resedaceæ.) An annual European plant, naturalized in the United States. It is inodorous, and has a bitter taste, which is very adhesive. Volhard showed that sulphocyanide of allyl, C_3H_5,SCN (oil of mustard), was present in the root, and Chevreul obtained from it by sublimation a peculiar yellow coloring matter, which he called *luteolin*, and which has the formula $C_{20}H_{14}O_8$. Hlasiwetz and Pfaundler (1895) assign to it the formula $C_{15}H_{10}O_6$. This forms yellow crystals of silky lustre, insoluble in water, soluble in alcohol. It dissolves in alkalies with deep yellow color. It is used especially in silk-dyeing. Rochleder and Brener (*Journ. Prakt. Chem.*, xcix. 433) found that when fused with caustic potash it was decomposed into phloroglucin and protocatechuic acid with evolution of carbon dioxide. A. G. Perkin (*Journ. Chem. Soc.*, 1896) investigated the salts of luteolin, and calls attention to the similarity of its properties to those of *fisetin*. In medicine it has been employed as a diaphoretic and diuretic, but it is now used only for dyeing purposes.

RESOL. A proprietary disinfectant said to be made by saponifying wood-tar with caustic potash and adding wood-spirit. It is used as a bactericide.

RESORBIN. An ointment vehicle made by emulsifying almond oil and water by means of a little yellow wax, gelatin, and soap, to which is added some lanolin. It is asserted that it greatly facilitates the absorption of medicaments.

RETINOL. *Codol.* A product obtained by the distillation of Burgundy pitch or resin. It forms a yellowish oil boiling at temperatures over 280° C. It is stated that retinol does not irritate the skin, is unaltered by light, is mildly antiseptic, does not become rancid, and is very inexpensive; qualities which, taken along with its extraordinary solvent power, bid fair to make it a valuable basis for ointments. Among the substances dissolved by it are: salol, 1–10; iodol, 1–50; naphtol, 1–50; aristol, 1–50; camphor, 1–20; chrysophanic acid, 1–40; cocaine, 1–30; codeine, 1–40; and strychnine, 1–40. It is miscible in all proportions with oil of juniper, carbolic acid, turpentine, alcohol, and ether. Resorcin, if dissolved in glycerin, may be mixed with retinol, and so may iodoform if it be dissolved in a little ether. Iodol is dissolved, but soon precipitates as a resinous mass. Phosphorus is also dissolved, and the solution remains unchanged indefinitely. Retinol mixes readily with fats, oils, vaseline, lard, lanolin, glycerin, cacao butter, etc., and may be used in ointments. In cases where a liquid is not undesirable, retinol, owing to its antiseptic properties, can with great advantage replace these bodies. Upon mucous membranes retinol seems to act as a mild stimulant antiseptic; it has been used with alleged excellent results locally in *otitis, vaginitis, rhinitis,* and other mucous diseases. Injections of it in *gonorrhœa* are said to be remarkably effective. As a means of administering phosphorus it is especially recommended.

RHIGOLENE. This name was given by H. J. Bigelow, of Boston, to a very light, inflammable liquid, obtained by distilling petroleum, and separating the liquids of the lowest boiling point by redistillation, until one is obtained which boils at about 18° C. (64·4° F.). A degree of cold —9° C. (15·8° F.) is, according to Dr. Bigelow, obtained through the evaporation of this liquid by means of the common atomizer or "spray-producer." This is the chief use of the liquid, which may be employed in producing congelation of any part of the body preparatory to a surgical operation, or a great degree of cold for any other purpose. It should, when not in use, be kept in a cool place, in bottles tightly corked, or otherwise it will be rapidly evaporated. In a warm place it might break the bottles through its extreme volatility, unless the stopper should previously be driven out. It has been accused of being liable to explosion; but this is not true, unless the vapor should be mixed in certain proportions with atmospheric air and then approached by a burning body.

RHODODENDRON CHRYSANTHUM. Pall. *Yellow-flowered Rhododendron. Rosebay, Snowrose. Rosage,* Fr. *Alpenrose, Schneerose, Gichtrose,* G. (Nat. ord. Ericaceæ.) The leaves of this Siberian rhododendron, when fresh, have a feeble odor, said to resemble that of rhubarb. In the dried state they are inodorous, but have an austere, astringent, bitterish taste. They yield their virtues to water and alcohol. They are stimulant, narcotic, and diaphoretic, producing, when first taken, increase of heat and arterial action, subsequently a diminished frequency of the pulse, and, in large doses, vomiting, purging, and delirium. They have been long employed in Siberia as a remedy in *rheumatism;* and their use has extended to various parts of Europe. Their action is said to be accompanied by a sensation of creeping or pricking in the affected part, which subsides in a few hours, leaving the part free from pain. They have been recommended also in *gout, lues venerea,* and *palsy.* In Siberia they are prepared by infusing two drachms of the dried leaves in about ten ounces of water, in a close vessel, and keeping the liquid near the boiling point during the night. The strained liquor is taken in the morning; and a repetition of the dose three or four

days successively generally effects a cure. G. F. Kuehnel found in leaves of the "great laurel" *Rhododendron maximum*, *arbutin*, *ericolin*, and *ursone*. (*A. J. P.*, 1885.)

RHUS AROMATICA. Ait. (Nat. ord. Anacardiaceæ.) This drug has been highly recommended in the treatment of *nocturnal incontinence* of urine by a number of clinicians of repute. (See *Gaz. Hebdom.*, 1889; also *Annals of Gynæc.*, 1890.) The adult dose is twenty or thirty minims (1·3 or 1·9 C.c.) of the fluid extract of the bark, three times a day, given in aromatized solution. For elaborate description of bark, see *Newer Materia Medica*.

RIGA BALSAM. *Balsamum Carpaticum. Balsamum Libani.* This is usually stated to be a product of *Pinus Cembra*, L. (nat. ord. Coniferæ), a large tree growing in the mountainous regions and northern latitudes of Europe and Asia. The juice exudes from the extremities of the young twigs, and is collected in flasks suspended from them. It is a thin, white fluid, having an odor analogous to that of the juniper, and possessing the ordinary terebinthinate properties. In this country it is very rare; but it is occasionally brought from Riga or Cronstadt in bottles. M. Keller, of Darmstadt, affirms that Riga Balsam is nothing but the product of the ordinary *Pinus palustris*, Mill. A similar product, called *Hungarian balsam*, is obtained in the same manner from *Pinus pumilio*, Haenke, growing on the mountains of Switzerland, Austria, and Hungary. The oil derived from the young branches of the *Pinus pumilio* (*Oleum pini pumilionis*, *Oleum templinum*, *Krummholzöl*, *Pumiline*) is the most potent agent in the so-called *pine cure* in the German spas. Schimmel & Co. (*Report*, April, 1897) find it to contain *lævo-pinene*, *lævo-phellandrene*, and other terpenes, and from 4 to 7 per cent. of *bornyl acetate*, boiling above 185° C. When pure, it is said to be a very fragrant volatile oil, especially adapted for the purposes of inhalation. Internally it may be given in doses of from five to ten minims (0·3–0·6 C.c.), in capsules, as a stimulant expectorant.

ROBINIA PSEUDACACIA, L. *Locust-tree. False Acacia. Robinier*, Fr. *Falsche Akazie*, G. (Nat. ord. Leguminosæ.) This well-known indigenous tree has a place in the Materia Medica of the "eclectics." The bark of the root is the most active part, and is said to be tonic, and in large doses purgative and emetic. Dr. F. B. Power and J. Cambier (*Pharm. Rundschau*, Feb. 1890) found a small amount of an alkaloid which they showed to be identical with *choline*. They also isolated a globulin and an albumose. This *phyt-albumose* produces purging and vomiting. It is precipitated by alkaloidal reagents. Zwenger and Dronke (*Ann. Chem. Pharm.*, Supp., i. 257) found a glucoside, *robinin*, $C_{25}H_{30}O_{16}$, which, treated with dilute acids, yielded *quercetin* and a sugar. Hlasiwetz obtained *asparagin*, $C_4H_8N_2O_3$, from the root. The bark also contains a poisonous albuminoid or enzyme, *robinalbin*, which, according to Prof. Kobert (*Merck's Bull.*, April, 1891), is similar to but not identical with ricin. Three cases of the poisoning of children by the root have been recorded. (*Ann. de Thérap.*, 1860, 64.) Dr. Z. T. Emery (*N. Y. Med. Journ.*, Jan. 22, 1887) reports the poisoning of thirty-two boys from chewing the inner bark of the tree. The symptoms in the mildest cases were vomiting and flushed face, dryness of the throat and mouth, and dilated pupils. In the severest cases to these were added epigastric pain, extremely feeble, intermittent, heart-action, and stupor.

Robinia Nicon. According to the researches of M. Geoffroy (*Annal. de l'Inst. botanico-geologique colon. de Marseille*, 1895), this leguminous plant, which is used in Guiana for the purpose of stupefying fish, contains an active principle, *niconline* (C_5H_4O), which crystallizes in oblique, rhomboidal tables. It has been found by E. Boinet (*Compt.-Rend. de la Soc. de Biolog.*, 1896, 10 s., iii.) to produce in the lower animals a short primary stage of excitation, followed by one of stupor, great muscular relaxation, enfeeblement of sensibility, mydriasis, fall of temperature, cyanosis, and death through centric paralysis of the respiration, though there is also fall of arterial pressure. In the dog there were salivation and vomiting.

ROTTEN STONE. *Terra Cariosa.* An earthy mineral, occurring in light, dull, friable masses, dry to the touch, of a very fine grain, and of an ash-brown color. It is obtained from Derbyshire, in England, and is used for polishing metals. For a particular account of it, see *A. J. P.*, 1860, 463.

ROUREA OBLONGIFOLIA. Hook. and Arn. (Nat. ord. Connaraceæ.) This Mexican creeper is affirmed to contain an alkaloid, and to act as a violent convulsant poison. (*El Estudio*, 1890.)

RUBIA. *Garance*, Fr. *Krappwurzel*, *Färberröthe*, G. *Robbia*, It. *Rubia de tintoreros*, *Granza*, Sp. Under this name the U. S. P. formerly recognized *madder*, *Rubia tinctorum*, L. (nat. ord. Rubiaceæ). The root of *dyer's madder* is perennial, and consists of numerous long, succulent fibres, varying in thickness from the size of a quill to that of the little finger, and uniting at top in a common head, from which also proceed side-roots that run near the surface of the ground, and send up many annual stems. These are slender, quadrangular, jointed, procumbent, and furnished with short prickles, by which they adhere to the neighboring plants upon which they climb. The leaves are elliptical, pointed, rough, firm, about three inches long and nearly one inch broad, having rough points on their edges and midrib, and standing at the joints of the stem in whorls of four, five, or six together. The branches rise in pairs from the same joints, and bear small yellow flowers at the summit of each of their subdivisions. The fruit is a round, shining, black berry. The plant is a native of the south of Europe and the Levant, and is cultivated in Asia Minor, France, Holland, and the south of Italy. The root, which is the part used, is dug up in the third summer, and, having been deprived of its cuticle, is dried by artificial heat, and then reduced to a coarse powder. In this condition it is packed in barrels and sent into the market. Madder from the Levant is in the state of the whole root; from the south of France, either whole or in powder. The plant was also cultivated in this country, in the States of Delaware and Ohio. The root consists of a reddish-brown bark, and a ligneous portion within. The latter is yellow in the recent state, but becomes red when dried. The powder as found in commerce is reddish brown. Madder has a weak, peculiar odor, and a bitterish, astringent taste, and imparts these properties, as well as a red color, to water and alcohol. It contains as its most important constituent *alizarin*,

$C_{14}H_6(OH)_2O_2$, and with it as coloring matter of secondary importance *purpurin*, $C_{14}H_5(OH)_3O_2$. Besides these two technically important constituents there have been recognized *pseudopurpurin*, an orange dye-color, and a yellow one (*xanthopurpurin*). These coloring matters, however, are probably decomposition products from glucosides existing in the fresh plant. Thus, alizarin is known to result along with glucose from the treatment with dilute acids of *rubianic* or *ruberythric acid*, $C_{26}H_{28}O_{14}$, according to the reaction: $C_{26}H_{28}O_{14} + 2H_2O = C_{14}H_8O_4 + 2C_6H_{12}O_6$. The most interesting of the coloring substances is the *alizarin*. It may be obtained from the alcoholic extract by sublimation, in the method employed by Mohr in obtaining benzoic acid. (*Journ. de Pharm.*, 3e sér., xxxi. 267.) It is orange-red, inodorous, insipid, crystallizable, capable of being sublimed without change, scarcely soluble in cold water, soluble in boiling water, and very readily so in alcohol, ether, the fixed oils, and alkaline solutions. The alcoholic and watery solutions are rose-colored; the ethereal, golden yellow; the alkaline, violet and blue when concentrated, but violet-red when sufficiently diluted. A beautiful rose-colored lake is produced by precipitating a mixture of the solutions of alizarin and alum. Alizarin was recognized by Graebe and Liebermann in 1868 as a derivative of anthracene, $C_{14}H_{10}$,—a hydrocarbon contained in coal-tar,—and in the same year they elaborated a method for preparing it commercially from anthracene. Upon this arose rapidly a great chemical industry, so that in 1881 the amount of artificial alizarin annually produced was 14,000 tons of 10 per cent. paste, valued at $8,000,000. The production of madder, of course, decreased correspondingly. The exportations of madder from France, which in 1872 had a value of $1,850,000, decreased to $70,000 in 1878, and $53,000 in 1883. The importations of alizarin into the United States for the last three years were as follows: for 1896, 6,152,776 lbs., valued at $994,230; for 1897, 6,148,268 lbs., valued at $1,022,970; for 1898, 5,872,015 lbs., valued at $886,332. Madder also contains sugar; and Döbereiner succeeded in obtaining alcohol from it by fermentation and distillation, without affecting its coloring properties.

Madder is used in *amenorrhœa* and *dropsy*, and when taken into the stomach imparts a red color to the milk and urine, and to the bones of animals, without sensibly affecting any other tissue. The effect is observable most quickly in the bones of young animals, and in those nearest the heart. Under the impression that it might effect some change in the osseous system, it has been prescribed in *rachitis*, but without favorable result. Dose, about half a drachm (1·9 Gm.), repeated three or four times a day.

RUBIDIUM. Salts of rubidium may be obtained much more cheaply than in former years, on account of Erdmann's process for the recovery of these salts from the Stassfurt potash deposits. Two salts have been brought forward for use in practical medicine.

Rubidium iodide, RbI, which occurs in whitish crystals, very soluble in water, and has been recommended by Harnack, Neisser, and others as a substitute for the potassium iodide, than which it is asserted to be better borne by the stomach. The dose is that of potassium iodide.

Rubidium ammonium bromide, $RbBr.3NH_4Br$, was recommended by Laufenauer as an antileptic in doses up to two drachms a day.

Rubidium bromide, Rb.Br, is now upon the market, and may be used as a substitute for, and in the dose of, potassium bromide, than which it is said to be better borne, especially by feeble patients.

RUBUS CHAMÆMORUS. L. *Cloud Berry.* (Nat. ord. Rosaceæ.) This plant, which inhabits the northern portions of both continents, is largely employed in Northern Russia, in the form of an infusion of the berries or leaves, as a diuretic in *dropsy*. Dr. Popoff found in it a crystallizable acid which is an essential diuretic, acting directly upon the renal secreting structures without affecting either cardiac action or arterial tension. (*Vrach*, iv., 1886.)

RUTA. Under this name the U. S. P. formerly recognized the *Ruta graveolens*. L. *Common rue* (*Rue odorante*, Fr.; *Garten-Raute*, G.; *Ruta*, It.; *Ruda*, Sp.) is a perennial plant (nat. ord. Rutaceæ), usually two or three feet high, with several shrubby branching stems, which, near the base, are woody and covered with a rough bark, but in their ultimate ramifications are smooth, green, and herbaceous. The leaves are doubly pinnate, glaucous, with obovate, sessile, obscurely crenate, somewhat thick and fleshy leaflets. The flowers are yellow, and disposed in a terminal branched corymb upon subdividing peduncles. The calyx is persistent, with four or five acute segments; the corolla consists of four or five concave petals, somewhat sinuate at the margin. There are usually ten stamens, but sometimes only eight. The plant is a native of the south of Europe, but cultivated in our gardens. It flowers from June to September. The whole herb is active, and yields its properties to water and alcohol. The leaves have a strong disagreeable odor, especially when rubbed. Their taste is bitter, hot, and acrid. When recent, and in full vigor, they have so much acrimony as to inflame and even blister the skin, if much handled; but the acrimony is diminished by drying. Their virtues depend chiefly on a volatile oil, which is contained in glandular vesicles, apparent over the whole surface of the plant. They contain, also, according to Mähl, chlorophyll, albumen, a nitrogenous substance, extractive, gum, starch or inulin, malic acid, and lignin; and, according to Borntträger, a peculiar acid which he calls *rutinic acid*, $C_{25}H_{28}O_{15}$ (or $C_{27}H_{32}O_{16}$, according to later writers). Rutinic acid is the coloring principle of rue, and has been found in various other plants; though, like quercitrin, yielding quercetin and sugar, it has been shown to be distinct. (*Journ. de Pharm.*, 1862, 165.)

Rue yields a very small proportion of a yellow or greenish volatile oil, which becomes brown with age. According to Zeller, the product from the fresh herb is 0·28 per cent., that from the seeds about 1 per cent. The oil has the strong unpleasant odor of the plant, and an acrid taste. Kane gives its sp. gr. at 0·837, its boiling point at 230° C. (446° F.). "A neutral reaction. Sp. gr. about 0·880. It is soluble in an equal weight of alcohol." *U. S.* 1880. It consists mainly of an oxidized constituent, which Strecker proved to be *methyl-nonyl-ketone*, $CH_3.CO.C_9H_{19}$; that is, a ketone analogous to acetone, $CH_3.CO.CH_3$. This accounts for its yielding under treatment with oxidizing

agents pelargonic acid, $C_9H_{18}O_2$. The methyl-nonyl-ketone, when pure, is a colorless liquid, fluorescing blue, boiling at 225° C. (437° F.), and crystallizing at about 15° C. (59° F.). When treated with nitric acid, it yields, among other products, pelargonic acid. Schimmel & Co. (*Report*, 1892, 31) state that pure oil of rue consists of 90 per cent. of methyl-nonyl-ketone, and solidifies even at a moderate temperature to a solid, crystalline mass, and has the sp. gr. 0·837.

Rue is said to have been used by the ancients as a condiment. In modern times it has been employed in *hysteria*, *worms*, *colic*, and atonic *amenorrhœa* and *menorrhagia*. Its medical activity depends upon its volatile oil, which is a powerful local irritant, causing, when applied to the skin persistently, burning, redness, and vesication, and when taken internally in large doses, violent gastric pains and vomiting, great prostration, confusion of mind, convulsive twitching, and in pregnant women abortion. It has been considerably used in Europe for the production of criminal *abortion*, in a number of cases with fatal results. The dose is from two to five drops every two or three hours. The rue itself is sometimes given in the dose of from ten to thirty grains (0·648–1·94 Gm.). In a case of fatal poisoning in a man, reported by Dr. G. F. Cooper, there were vomiting, violent tormina and tenesmus, with bloody stools, great abdominal distention, with tenderness and severe strangury. (*Med. Ex.*, N. S., ix. 720.)

SABADILLA. *Cevadilla.* The dried ripe seeds of *Schœnocaulon officinale*, A. Gray (*Asagræa officinalis*, Lindl.), were recognized by the Br. Pharm. of 1885. At one time cevadilla was generally believed to be derived from *Veratrum sabadilla*, Retz. Schiede, during his travels in Mexico, ascertained that it was, in part at least, collected from a different plant, of the same natural order of Liliaceæ, growing upon the eastern declivity of the Mexican Andes. This was considered by Schlechtendal as another species of Veratrum, by Don as an Helonias, and by Lindley as belonging to a new genus which he named Asagræa. Hence it has been variously denominated *Veratrum officinale*, Schlecht. and Cham., *Helonias officinalis*, D. Don, *Asagræa officinalis*, Lindl., and *Schœnocaulon officinale*, A. Gray. It is not probable that *Veratrum sabadilla*, Retz, yields much, if any, of the seed of commerce; but it would seem that very much of the drug is the product of a plant so different from *Schœnocaulon officinale* that Ernst, of Carácas, believes it to be a new species. It differs chiefly in having its leaves broader and more carinate.

Cevadilla seeds usually occur in commerce mixed with the fruit. This consists of three coalescing capsules or follicles, which open above and appear like a single capsule with three cells. It is three or four lines long and a line and a half in thickness, obtuse at the base, light brown or yellowish, smooth; each of the component capsules contains one or two seeds. A resemblance, existing or supposed, between this fruit and that of barley is said to have given rise to the Spanish name cevadilla, which is a diminutive of barley. The seeds are elongated, pointed at each end, flat on one side and convex on the other, somewhat curved, two or three lines long, wrinkled, slightly winged, black or dark brown on the outside, whitish within, hard, inodorous, and of an exceedingly acrid, burning, and durable taste.

Pelletier and Caventou first noted the presence of an alkaloid in cevadilla, which base they called *veratrine;* Meissner in the same year announced the presence of an alkaloid, *sabadilline*, and Couërbe, Merck, and Weigelin all described what they considered as distinct bases; but its exact composition remained unsettled until Wright and Luff (*Journ. Chem. Soc.*, 33, 338) found in it three bases: 1, *cevadine*, $C_{32}H_{49}NO_9$ (agreeing with the base described by Merck as veratrine), crystallizing in needles or compact crystals, fusing at 205° C. (401° F.) (202° C. (395·6° F.) according to Merck), insoluble in water, easily soluble in alcohol and ether, and decomposed by hot alcoholic potash into *cevine*, $C_{27}H_{43}NO_8$ ($C_{27}H_{45}NO_9$, Flückiger), and methyl-crotonic acid (cevadic acid of Pelletier and Caventou), $C_5H_8O_2$; 2, *veratrine*, $C_{37}H_{53}NO_{11}$, obtained from the syrupy mother-liquor from which the cevadine has crystallized; it is uncrystallizable, soluble in ether, and decomposed by alcoholic soda into *verine*, $C_{28}H_{45}NO_8$, and dimethyl-protocatechuic acid (veratric acid of Merck), $C_7H_4(CH_3)_2O_4$; 3, *cevadilline*, $C_{34}H_{53}NO_8$, obtained after the extraction of the veratrine with ether; it is insoluble in ether, slightly soluble in boiling benzol, and readily soluble in fused oil, uncrystallizable, and appears to yield methyl-crotonic acid on treatment with alcoholic soda.

The second of these alkaloids, *veratrine*, Flückiger considers as isomeric with cevadine, $C_{32}H_{49}NO_9$, and writes the reaction for its decomposition,

$$2C_{32}H_{49}NO_9 + 4H_2O = \underset{\text{Dimethylprotocatechuic acid.}}{C_9H_{10}O_4} + \underset{\text{Veratroine.}}{C_{55}H_{92}N_2O_{16}} + 2H_2O.$$

(*Pharmaceut. Chem.*, 2d ed., 1888, 531.)

Wright and Luff extract the alkaloids as follows. One hundred parts of sabadilla seeds are exhausted with one part of tartaric acid and alcohol, the alcoholic extract concentrated, freed from resinous admixture by addition of water, and then treated with soda and ether. The ethereal solution is then shaken up with aqueous tartaric acid solution, and the acid liquid again treated with soda and ether. The ethereal solution is now mixed with ligroin (petroleum benzin), and allowed to evaporate spontaneously. A syrupy liquid separates out first, and then crystals of cevadine, which are drained off and recrystallized from alcohol. The residual syrupy liquid consists essentially of veratrine and cevadilline. Ten kilogrammes of seeds yield from sixty to seventy grains of alkaloids, from which eight to nine grains of pure cevadine, five to six grains of veratrine, and two to three grains of crude cevadilline can be isolated.

Merck has since (*Merck's Report*, Jan. 1891, 3–9) isolated two new alkaloids from cevadilla, which he names *sabadine* and *sabadinine* respectively. The former has the formula $C_{29}H_{51}NO_8$, crystallizes from ether in short needles, and fuses at from 238°–240° C. It dissolves in concentrated sulphuric acid with a yellow color and a green fluorescence, which gradually disappears, while the liquid assumes a blood-red and then violet color. The alkaloid is sternutatory, although in a much less degree than veratrine. The second alkaloid crystallizes from ether in filiform needles, which begin to sinter at 160° C., but show no fixed fusing point. Concentrated sulphuric acid causes a permanent blood-red color. The formula is given

as $C_{27}H_{45}NO_8$. The alkaloid is not sternutatory. Cevadilla yields about 0·3 per cent. of veratrine. (See *Veratrina.*)

Cevadilla is an acrid, drastic emeto-cathartic, operating occasionally with great violence, and in overdoses capable of producing fatal effects. Known in Europe as early as 1752, and formerly used to some extent as a tænicide, in doses of from five to twenty grains (0·33–1·3 Gm.), it is now official solely as the source of veratrine. It is the principal ingredient of the *pulvis Capucinorum*, sometimes used in Europe for the destruction of *vermin in the hair*.

SABBATIA. *Centaurée Américaine*, Fr. *Sabbatie*, G. Of this gentianaceous genus three American species are more or less used in popular medicine as tonics and as antiperiodics. They are, in fact, simple bitters of some activity, and may very well be substituted for the foreign remedies of their class. Their value in intermittent fever is probably simply that of quassia and gentian, only somewhat more feeble. The *S. angularis* (L.), Pursh, or *American centaury*, was formerly recognized by the U. S. Pharmacopœia in its Secondary List. A description of it may be found in the 16th edition of the *U. S. D.* Mr. John F. Huneker found in it a small proportion of *erythrocentaurin*, $C_{27}H_{24}O_8$, previously discovered by M. Méhu, a French chemist, in *Erythræa centaurium*, Pers., of Europe. Mr. Huneker also obtained from American centaury resin, chlorophyll, fatty matter, gum, albumen, pectin, bitter extractive, traces of volatile oil, an organic acid, red coloring matter, and salts. (*A. J. P.*, 1871, 207.)

In the Southeastern United States, the *Sabbatia elliottii*, Stend., or *Quinine flower*, and in the Southwestern United States the *Sabbatia campestris*, Nutt., have been employed like the *S. angularis* in the North. They probably contain the same active principle. Of the *S. angularis* and the *S. campestris* the whole plant is used, the dose being a drachm (3·88 Gm.), given in the form of fluid extract or in decoction. Of the Quinine flower, the root is employed; dose of the fluid extract, one fluidrachm (3·69 C.c.); in intermittent fever to be repeated at short intervals.

SAGAPENUM. This gum-resin, formerly highly esteemed, but at present very rarely met with even in Eastern commerce, is the concrete juice of an unknown Persian plant, supposed by some to be one of the species of Ferula (nat. ord. Umbelliferæ) related to those that yield galbanum. It is in irregular masses, composed of agglutinated fragments, slightly translucent, of a brownish-yellow, olive, or reddish-yellow color externally, paler internally, brittle, of a consistence somewhat resembling that of wax, and often mixed with impurities, especially with seeds more or less entire. An inferior variety is soft, tough, and of uniform consistence. It has an alliaceous odor less disagreeable than that of asafetida, and a hot, nauseous, bitterish taste. It softens and becomes tenacious by the heat of the hand. The effect of time and exposure is to harden and render it darker. It is inflammable, burning with a white flame and much smoke, and leaving a light spongy charcoal. Pure alcohol and water dissolve it partially, diluted alcohol almost entirely. Distilled with water it affords a small quantity of volatile oil, and the water is strongly impregnated with its flavor. According to Pelletier, it contains 56 per cent. of resin, 31·94 of gum, 1·0 of bassorin, 0·40 of acidulous calcium malate, and 11·80 of volatile oil. The ether soluble resin of Sagapenum can be separated by saponification into 16 per cent. of *umbelliferone* and 40 per cent. of *sagaresitannol*, $C_{24}H_{27}O_4.OH$. This latter yields on oxidation *oxypicric acid*. Brandes found 3·73 per cent. of volatile oil. This is pale yellow, very fluid, lighter than water, and of a disagreeable alliaceous odor. Flückiger found the oil devoid of sulphur, but to contain *umbelliferone*. (*Pharmacographia*, 324.) Sagapenum was considered by the older physicians as midway in its medical properties between asafetida and galbanum, and was used in doses of from ten to thirty grains (0·648–1·9 Gm.) in *amenorrhœa, hysteria*, etc.; also externally in plasters as a discutient.

SAGO. *Sagou*, Fr. *Sago*, G., It. *Sagu*, Sp. Under this name the U. S. P. formerly recognized the starch obtained from the sago palms. Numerous trees, inhabiting the islands and coasts of the Indian Ocean, contain a farinaceous pith, which is applied to the purposes of nutriment by the natives. Such are *Sagus rumphii*, Willd. (now *Metroxylon sagu*, Rottb.), *Sagus lævis*, Jack (now *Metroxylon sagu*, Rottb.), *Sagus ruffia*, Jacq. (now *Raphia pedunculata*, Beauv.), *Saguerus rumphii*, Roxb. (now *Arenga saccharifera*, Labill), and *Phœnix farinifera*, Roxb., belonging to the family of Palms; and *Cycas circinalis*, *Cycas revoluta*, and *Zamia lanuginosa*, belonging to the Cycadaceæ. Of these, *Sagus rumphii*, *Sagus lævis*, and *Saguerus rumphii* probably contribute to furnish the sago of commerce. Crawford, in his *History of the Indian Archipelago*, states that it is derived exclusively from *Metroxylon sagu*, Rottb., but Roxburgh ascribes the granulated sago to *S. lævis*, Jack (which subsequent research shows to be *Metroxylon sagu*, Rottb.); and one of the finest kinds is said by Dr. Hamilton to be produced by the *Saguerus rumphii*, Roxb. (now recognized as *Arenga saccharifera*, Labill). The farinaceous product of the different species of Cycas, sometimes called *Japan sago*, does not enter into general commerce.

Sagus rumphii, Willd. *Sp. Plant.* iv. 404; Carson, *Illust. of Med. Bot.* ii. 44, pl. 88. *Metroxylon sagu*, Rottb. (1783); *Bentley and Trimen*, 278. The *sago palm* is one of the smallest trees of its family. Its extreme height seldom exceeds thirty feet. The trunk is proportionately very thick, quite erect, cylindrical, covered with the remains of the old leafstalks, and surrounded by a beautiful crown of foliage, consisting of numerous, very large, pinnate leaves, extending in all directions from the summit, and curving gracefully downward. The fruit is a roundish nut, covered with an imbricated coat, and containing a single seed.

The tree is a native of the East India islands, growing in the Peninsula of Malacca, Sumatra, Borneo, Celebes, the Moluccas, and a part of New Guinea. It flourishes best in low and moist situations. Before attaining maturity, the stem consists of a shell, usually about two inches thick, filled with an enormous volume of spongy medullary matter like that of elder. This is gradually absorbed after the appearance of fruit, and the stem ultimately becomes hollow. The greatest age of the tree is not more than thirty years. Large quantities of a kind of sugar called *jaggary* are produced from its juice. According to H. von Rosenberg (*Proc. A. P. A.*, xxvii. 140), the medullary

matter consists mostly of starch when the large leaves have fallen off and the flowers are just taking their place. At this time the tree is felled, and the trunk cut into billets six or seven feet long, which are split in order to facilitate the extraction of the pith. This is obtained in the state of a coarse powder, which is mixed with water in a trough having a sieve at the end. The water, loaded with farina, passes through the sieve, and is received in convenient vessels, where it is allowed to stand till the insoluble matter has subsided. It is then strained off, and the farina which is left may be dried into a kind of meal or moulded into whatever shape may be desired. For the consumption of the natives it is usually formed into cakes of various sizes, which are dried, and extensively sold in the islands. The commercial sago is prepared by forming the meal into a paste with water, and rubbing it into grains. It is produced in the greatest abundance in the Moluccas, but of the finest quality on the eastern coast of Sumatra. The Chinese of Malacca refine it so as to give the grains a fine pearly lustre. Malcom states that it is also refined in large quantities at Singapore. In this state it is called *pearl sago*, and is in great repute. It is said that five or six hundred pounds of sago are procured from a single tree.

Pearl sago is that which is now generally used. It is in small grains, about the size of a pin's head, hard, whitish, of a light brown color, in some instances translucent, inodorous, and with little taste. It may be rendered perfectly white by a solution of chlorinated lime. *Common sago* is in larger and browner grains, of more unequal size, of a duller aspect, and frequently mixed with more or less of a dirty looking powder.

Sago meal is imported into England from the East Indies. It is in the form of a fine amylaceous powder, of a whitish color, with a yellowish or reddish tint, and of a faint but somewhat musty odor.

Common sago is insoluble in cold water, but by long boiling unites with that liquid, becoming at first soft and transparent, and ultimately forming a gelatinous solution. Pearl sago is partially dissolved by cold water, probably owing to the heat used in its preparation. Chemically considered, it is a very pure natural starch, as the nitrogenous matter rarely amounts to more than one per cent., and the ash to one-half per cent., the remainder being starch and moisture. Under the microscope the granules of sago meal appear oval or ovate, and often truncated so as to be more or less muller-shaped. Many of them are broken, and in most the surface is irregular or tuberculated. They exhibit upon their surface concentric rings, which are much less distinct than in potato starch. The hilum is circular when perfect, and cracks either with a single slit or a cross, or in a stellate manner. The granules of pearl sago are of the same form, but are all ruptured, and exhibit only indistinct traces of the annular lines, having been altered in the process employed in preparing them. Those of common sago are very similar to the particles of sago meal, except that they are perhaps rather less regular and more broken.

Potato starch is sometimes prepared so as to resemble bleached pearl sago, for which it is sold. But, when examined under the microscope, it exhibits larger granules, which are also more regularly oval or ovate, smoother, less broken, and more distinctly marked with the annular rugæ than are those of sago; and the hilum often cracks with two slightly diverging slits. Sago is now made in the United States from various kinds of starch.

Sago is used exclusively as an easily digestible, non-irritating food. It is given in the liquid state, and in its preparation care should be taken to boil it long in water, and stir it diligently, in order that the grains may be thoroughly dissolved. Should any portion remain undissolved, it should be separated by straining. A tablespoonful to the pint of water is usually sufficient.

SALACETOL. *Salicyl-acetol. Salantol Salantol.* $C_6H_4(OH)CO.OCH_2CO.CH_3$. A synthetic product, the ester of salicylic acid and acetylcarbinol, introduced as a substitute for salol, to avoid the elimination of phenol in the system. Crystallizes out of alcohol in needles, fusing at 71° C., slightly soluble in cold water and alcohol, readily soluble in ether, chloroform, and benzin. It may be used when salol is indicated, in doses of from thirty to forty-five grains (1·9–2·9 Gm.).

SALACTOL. A mixture of the sodium salts of salicylic and lactic acids, said to contain 71·1 per cent. of salicylic acid. A 1 per cent. solution of salactol in solution of hydrogen dioxide has been used to arrest the growth of diphtheritic membrane.

SALEP. *Tubera Salep*, P. G. *Salep*, Fr., G. This name is given to the dried tubers of numerous species of the genus *Orchis*, and in India of the genus *Eulophia*. At present the salep of European commerce is prepared chiefly in the Levant, but to some extent in Germany and other parts of Europe. The German salep is said to be more translucent than the Levant.

Salep is in small, oval, irregular, ovoid or oblong tubers, rarely palmate, hard, horny, semi-transparent, of a yellowish color, a feeble odor, and a mild mucilaginous taste. It is sometimes kept in the state of powder. In composition and relation to water it is closely analogous to tragacanth, consisting of a substance insoluble but swelling up in cold water (*bassorin*), of another in much smaller proportion, soluble in cold water, and of minute quantities of saline matters. It also occasionally contains a little starch. It is highly nutritive, and may be employed for the same purposes as tapioca, sago, etc. Its mediæval and Oriental reputation as an aphrodisiac is unfounded. On account of its hardness, salep, in its ordinary state, is of difficult pulverization; but the difficulty is removed by macerating it in cold water until it becomes soft, and then rapidly drying it. *Royal salep*, said to be much used as a food in Afghanistan, has been identified by Dr. J. E. T. Aitchison as the product of *Allium macleanii*, Baker. (Nat. ord. Liliaceæ.) (*P. J. Tr.*, Sept. 1889.)

SALHYPNONE. $C_6H_4O(COC_6H_5)COOCH_3$. A benzoyl-methyl-salicylic ester which occurs in colorless needles, insoluble in water and sparingly soluble in alcohol and ether. It is a mild antiseptic.

SALICYLAMIDE. $C_6H_4\begin{cases}OH\\CONH_2\end{cases}$. This compound is prepared by the action of concentrated ammonia upon methyl salicylate. When purified, it occurs in perfectly colorless, thin, transparent plates, melting at 138° C., soluble in alcohol, ether, chloroform, and two hundred parts of water. Dr. W. B. Nesbitt finds that this substance, when given in toxic dose, paralyzes the motor nerves and centres, also the muscles, and has but little effect upon

blood-pressure. He believes that it is a safer remedy than salicylic acid, and has the advantage of greater solubility and more prompt action in smaller dose. Also, that it has analgesic and antipyretic properties which correspond. It may be given in doses of three grains (0·194 Gm.). The highest amount used was fifteen grains (0·972 Gm.), taken in nine hours. (*Therap. Gaz.*, Oct. 1891.)

SALICYLBROMANILID. *Antinervine.* This was first described as a mixture of bromacetanilid and salicylanilid, but a specimen analyzed by Ritsert was shown to be a mixture of ammonium bromide, salicylic acid, and acetanilid. Salicylbromanilid has been asserted to be a safe antipyretic and antineuralgic by Radlauer, of Germany, but C. S. Bradfute (*New England Monthly*, April, 1891) has found it to be a violent depressant of the heart. In *angina pectoris*, with high tension, he obtained relief by its use, but it seems to be a dangerous remedy. Dose, from five to ten grains (0·324–0·648 Gm.).

SALIFEBRIN. *Salicylanilid.* An antipyretic, made by heating together salicylic acid and acetanilid in molecular proportions. It is a colorless permanent powder, insoluble in water, freely soluble in alcohol.

SALIFORMIN. *Formin Salicylate. Hexamethylene-tetramin-salicylate. Urotropin Salicylate.* $(CH_2)_6N_4.C_6H_4(OH)COOH$. A colorless, crystalline powder, having an acidulous taste, soluble in water and alcohol, used as an antiseptic and for its supposed solvent powers on uric acid deposits. The daily dose is from fifteen to thirty grains (0·9–1·9 Gm.).

SALIGALLOL. *Pyrogallol Di-salicylate.* A resinous solid, soluble in two parts of acetone and fifteen parts of chloroform. Its solution in acetone has been used as an external application in skin diseases.

SALIPYRIN. (*Antipyrin Salicylate.*) $C_{11}H_{12}N_2O.C_7H_6O_3$. Prepared by the action of salicylic acid upon antipyrin, either at 100° C. or in solution. It occurs as a white coarsely crystalline powder, odorless, with a somewhat sweetish taste. It is readily soluble in alcohol and in benzene, and crystallizes from the former in hexagonal tables with a melting point of 91·5° C. According to Guttmann and to Kollmann (*Internat. Klin. Rundsch.*, Sept. 1890; also *München. Med. Wochensch.*, Nov. 1890), it is an active antipyretic and antirheumatic, which rarely produces toxic symptoms, although an eruption resembling that of antipyrin has been noted; the color of the urine is not affected, but tests show the presence of salicylates. Kollmann states that it sometimes vomits, and that the daily dose should never exceed forty-five grains (2·9 Gm.), and always be less than this in the beginning, as some individuals are intolerant of it. Salipyrin has been used to a considerable extent in all forms of *rheumatic diseases*, in *influenza*, in various *fevers*, in *migraine*, and in the whole class of diseases in which its component constituents have been found to be useful; also locally in *coryza*. The usual dose is from seven to fifteen grains (0·45–0·97 Gm.), in capsule or tablet, repeated every three or four hours, but some clinicians prefer a single large dose of forty-five grains (2·9 Gm.).

SALITANNOL. $C_{14}H_{10}O_7$. A condensation product of salicylic and gallic acids; it is a colorless powder, insoluble in water, ether, chloroform, and benzol, slightly soluble in alcohol, soluble in solutions of caustic alkalies. It is used as a surgical antiseptic.

SALITHYMOL. *Thymol Ester of Salicylic Acid.* $C_6H_3(CH_3)(C_3H_7)O.COC_6H_4(OH)$. This salt is prepared by acting on molecular quantities of sodium salicylate and thymol sodium with phosphorus trichloride. It is a colorless crystalline powder, of sweet taste, insoluble in water, very soluble in alcohol. It is used as an antiseptic. Dose, from fifteen to thirty grains (0·9–1·9 Gm.).

SALIX. *U. S.* 1880. Most of the species of the large genus Salix are possessed of similar medical properties. *S. russelliana*, Sm. (now *S. fragilis*, L.), which has been introduced into this country from Europe, is said by Sir James Smith to be the most valuable species. *S. purpurea*, L., a European species, is stated by Lindley to be the most bitter, and *S. pentandra* is preferred by Nees von Esenbeck. Many native species are in all probability equally active with the foreign. The younger Michaux speaks of the root of *S. nigra*, Marsh., or *black willow*, as a strong bitter, used in the country as an antiperiodic.

Salix alba, L., the species formerly recognized by the U. S. Pharmacopœia, the common European or white willow, is twenty-five or thirty feet in height, with numerous round spreading branches. The exstipulate leaves are alternate, upon short petioles, lanceolate, pointed, acutely serrate with the lower serratures glandular, pubescent on both sides, and silky beneath. The aments are terminal, cylindrical, and elongated, with elliptical-lanceolate, brown, pubescent scales. The stamens are two in number, yellow, and somewhat longer than the scales; the style is short; the stigmas two-parted and thick. The capsule is nearly sessile, ovate, and smooth. The white willow is now very common in this country. It flowers in April and May, and the bark is easily separable throughout the summer. That obtained from the branches rolls up when dried into the form of a quill, from one-twenty-fifth to one-twelfth of an inch in diameter, has a brown, more or less finely warty epidermis, is flexible, fibrous, and of difficult pulverization. The inner surface is brownish white, and smooth, the liber separating in thin layers. Willow bark has a feebly aromatic odor and a peculiar bitter astringent taste. It yields its active properties to water, with which it forms a reddish-brown decoction. Pelletier and Caventou found, among its ingredients, tannin, resin, a bitter yellow coloring matter, a green fatty matter, gum, wax, lignin, and an organic acid combined with magnesia. The proportion of tannin is so considerable that the bark has been used for tanning leather. The characteristic constituent of all species of willow, however, is *salicin*. Robert W. Beck (*A. J. P.*, 1891, 581) has determined the relative percentages of salicin and tannin as follows:

	Salicin.	Tannin.
In leaves of *S. lucida*, Muhl. . .	0·30 per cent.	6·48 per cent.
In bark of *S. lucida*, Muhl . . .	1·09 " "	3·58 " "
In bark of *S. alba*, L.	0·56 " "	4·26 " "
In bark of *S. nigra*, Marsh. . .	0·73 " "	3·29 " "

The bark of the willow is feebly tonic, but it is at present never employed in regular medicine.

SALOL-CAMPHOR. When three hundred parts of salol are rubbed with two hundred parts of camphor, and then gently warmed, a liquid is obtained insoluble in water, but miscible with fixed and volatile oils, ether, and alcohol, to which M.

Désesquelle has given the name of *salol-camphor*, and which he recommends as a local anæsthetic.

SALOPHEN. *Acetylparamidophenyl salicylate.* $C_6H_4\begin{cases}OH\\COOC_6H_4.NH(C_2H_3O)\end{cases}$. This new derivative contains 50·9 per cent. salicylic acid. It occurs in white crystalline leaflets, almost insoluble in water, freely soluble in alkalies, alcohol, and ether. It melts at 187° C.; precipitates from its alcoholic solution, with ferric chloride, violet; with bromine water, densely white. In warm alkaline solution it undergoes decomposition into salicylic acid and acetylparamidophenyl. It has been physiologically studied by Dr. Siebel (*Therap. Monat.*, Jan. 1892), who finds that it is broken up in the intestines, and is even decomposed to some extent when given hypodermically. About eight grammes per kilo were necessary to kill a rabbit, the symptoms being those of salicylic acid poisoning. By direct experiment acetylparamidophenyl was found to be practically free from poisonous properties. Salophen has been used by Guttmann, Siebel, Löwenthaler, and numerous later clinicians in all forms of *rheumatic* diseases. There seems to be no doubt as to its effectiveness, but there is no sufficient reason for believing that it is as certain in its action as one of the more ordinary salicylates. It is said, however, to be less disturbing to the digestion. It has been especially commended by De Wannemaeker in *pruritus*, and has also been used as an intestinal antiseptic. Daily dose, from forty-five to seventy-five grains (2·9–4·85 Gm.).

SALUBROL. *Tetra-bromo-methylene-di-antipyrin.* An inodorous powder, made by the action of bromine on methyl-antipyrin. It is non-poisonous, and is used as a local hæmostatic and antiseptic and as a substitute for iodoform.

SALUMIN. *Aluminum Salicylate.* $(C_6H_4(OH)COO)_6Al_2 + 3H_2O$. This salt, which is insoluble in water, is made by the interaction between solutions of sodium salicylate and a salt of aluminum; it is a reddish-white powder used in catarrhal affections of the nose and pharynx. A soluble salumin is made by combining ammonia with the insoluble salumin, to form *ammoniated aluminum salicylate*, the formula of which is $(C_6H_4\begin{cases}ONH_4\\COO\end{cases})_6Al_2 + 2H_2O$. It is used for preparing astringent and antiseptic washes.

SAMADERA BARK. This is the inner bark of a tree belonging to the family of Simarubaceæ, growing in Ceylon. It is intensely bitter, and probably contains quassin. For further particulars, see *P. J. Tr.*, 1872, 541.

SANDARACH. *Sandaraca. Gum Juniper. Sandaraque*, Fr. *Sandarak*, G. A resinous substance obtained from the *Callitris quadrivalvis*, Vent. (*Thuya articulata*, Vahl.), an evergreen tree (nat. ord. Coniferæ) growing in the north of Africa. It is in small, irregular, roundish oblong grains or tears, of a pale yellow color, sometimes inclining to brown, more or less transparent, dry and brittle, breaking into powder under the teeth, of a faint, agreeable odor increased by warmth, and of a resinous, slightly acrid taste. It melts with heat, diffusing a strong balsamic odor, and easily inflames. It is almost entirely soluble in ordinary alcohol, and entirely so in that liquid when anhydrous, and in ether. Heated oil of turpentine also dissolves the greater part of it, but very slowly. According to Unverdorben, it consists of three resins, varying in their relations to alcohol, ether, and oil of turpentine. The *sandaracin* of Geise, which remains after sandarach has been exposed to the action of ordinary alcohol, is a mixture of two of these resins. In Australia and Tasmania Callitris-trees grow in vast numbers, and produce a sandarach which is almost colorless, having highly refractive power, and a pleasant aromatic odor; becoming dark by age, and sometimes assuming a superficial mealiness. This Australian sandarach softens easily, but does not melt in boiling water, is gritty to the touch, and can scarcely be distinguished from the African drug. (*P. J. Tr.*, Jan. 1890.) For an elaborate description of Australian sandarach, see also *A. J. P.*, 1896, 215. Sandarach was formerly given internally, and entered into the composition of various ointments and plasters. At present it is used chiefly as a varnish and as incense; its powder (*Pounce*) is rubbed upon paper to prevent ink from spreading after letters have been scratched out.

SANICULA MARYLANDICA. L. *Sanicle. Sanicle*, Fr. *Sanikel*, G. The root of this indigenous umbellifer is popularly known in some parts of the country by the name of *black snakeroot*. It is fibrous and of an aromatic taste, and, according to C. I. Houck (*A. J. P.*, vol. xiv. 463), contains a volatile oil and a resin. It has been used in *intermittent fever*, and also in *chorea* by Dr. Zabriskie; dose of powder to children eight years old half a drachm three times a day. (*Am. Journ. of Med. Sci*, N. S., xii. 374.)

SANOFORM. *Di-iodo-methyl Salicylate.* $C_6H_2\begin{cases}COOCH_3\\OH\\I_2\end{cases}$. This substance is obtained by the action of iodine on methyl salicylate. (Oil of Wintergreen.) It is a crystalline, colorless, odorless, and tasteless powder, permanent in the light and air, and melting at 110° C. (230° F.), but may be heated up to 200° C. (392° F.) without decomposing. It is soluble in 200 parts of cold or 10 parts of hot alcohol, and readily in ether, chloroform, benzol, and carbon disulphide, but very insoluble in water or glycerin. It contains 62·7 per cent. of iodine. It forms with caustic alkalies salts which are sparingly soluble in water.

Sanoform, first introduced as a substitute for iodoform by A. Arnheim, would appear to afford an efficient antiseptic dressing for wounds. As it remains unchanged at high temperatures, it is readily sterilized, whilst its odorlessness gives it a great advantage over iodoform. Its absorption is extremely slow, as it does not appear in the urine after having been administered hypodermically until twenty-four hours have elapsed, and does not entirely disappear until after fourteen days. It is seemingly, therefore, less poisonous than iodoform. It may be used as a dusting powder or in the manufacture of a 10 per cent. gauze which can be sterilized by heating; or a 1 per cent. solution in collodion, or a 10 per cent. ointment may be employed. It has been employed with satisfaction in ophthalmic surgery by Radziejewski and by Jacobsohn.

SANTOLINA. A composite plant, *Santolina chamæcyparissus*, is stated to have long been used popularly against the round worm in Scotland. It has been analyzed by Mr. T. Maben (*P. J. Tr.*, xvi. 301), who finds in it a volatile oil and a considerable percentage of resin, with a bitter principle, which he believes to be an alkaloid and the active principle of the drug. The decoction of the plant

may be made by boiling half an ounce in a pint of water for half an hour, straining and making up to a pint. It is given in doses of five ounces to adults and half that quantity to children, repeated for four mornings, and then followed by a brisk cathartic.

SANTONINOXIME. $C_{15}H_{18}O_2.N.OH$. This substance was first prepared in 1889 by P. Guici (*Gazz. Chim.* xix. 367) by digesting at nearly 80° C. for three days five parts of santonin, four parts of hydroxylamine hydrochloride, fifty parts of strong alcohol, and four parts of precipitated calcium carbonate. It crystallizes in white silky needles, melts at about 217° C., is very slightly soluble in hot water, and turns the plane of polarized light to the left. Coppola states that this substance is a safe and reliable substitute for santonin, to be given in doses about three times as large.

SAPINDUS. Various tropical plants belonging to this genus of the Sapindaceæ contain saponin, and are largely used for cleansing purposes. Thus, in India are employed the pulp of the fruit of the *Sapindus detergens*, Roxb. (now *S. mukorossi*, Gærtn.), the capsules of S. *emarginatus* Vahl. (now *S. trifoliatus*, L.), the berries of *S. laurifolius*, Vahl. (now *S. trifoliatus*, L.), and in South America the oil and seed-vessels of *S. saponaria*. (*P. J. Tr.*, 1871, 585.) For the properties of saponin, see *Saponaria officinalis*, below.

SAPONARIA OFFICINALIS. L. *Soapwort. Saponaire, Savonnière*, Fr. *Seifenwurzel*, G. (Nat. ord. Caryophyllaceæ.) A perennial herbaceous plant, growing wild in this country in the vicinity of cultivation, but probably introduced from Europe. It is commonly known by the vulgar name of *bouncing bet*. It is one or two feet high, with smooth, lanceolate leaves, and clusters of conspicuous whitish or slightly purplish flowers, which appear in July and August. The root and leaves are employed. They are inodorous, and of a taste at first bitterish and slightly sweetish, afterwards somewhat pungent, continuing long, and leaving a slight sense of numbness on the tongue. They impart to water the property of forming a lather when agitated, like a solution of soap, whence the name of the plant was derived. This property, as well as the medical virtues of the plant, resides in *saponin*, $C_{32}H_{54}O_{18}$. This principle constitutes, according to Bucholz, its discoverer, 34 per cent. of the dried root, which contains also a considerable quantity of gum and a little bassorin, resin, and altered extractive, besides lignin and water. Saponin is obtained, though not absolutely pure, by treating the watery extract with alcohol and evaporating. When thoroughly purified (see *A. J. P.*, 1884, 274), it is a very white, amorphous, inodorous powder, which excites sneezing when inhaled by the nostrils, has a pungent, disagreeable taste, and is poisonous. It is soluble in water and official alcohol, but is insoluble in anhydrous alcohol, ether, and the volatile oils. Although a glucoside, according to Lautenbach (*Journ. Nerv. and Ment. Dis.*, 1879, 433), it unites with sulphuric acid to form long acicular crystals. Its aqueous solution froths when agitated. It is decomposed by dilute acids, though with some difficulty, into *sapogenin*, $C_{14}H_{22}O_2$, and sugar, or, according to Schiaparelli (*A. J. P.*, 1884, 275), into *saponetin*, $C_{40}H_{66}O_{15}$, and sugar, according to the reaction: $2C_{32}H_{54}O_{18} + 3H_2O = C_{40}H_{66}O_{15} + 4C_6H_{12}O_6$. Stütz (*Ann. der Phar. und Chem.*, 218, 250) studied the saponin from *Quillaja saponaria*, and, after purifying his preparation and making a series of acetyl derivatives therefrom, was led to give the formula $C_{19}H_{30}O_{10}$ to saponin. It has been found in various plants, as different species of Silene, Dianthus, Lychnis, and Anagallis, in *Acacia concinna*, *Acacia delibrata*, *Vaccaria vulgaris*, *Agrostemma githago*. (*Journ. de Pharm.*, 3e sér., x. 339; also *P. J. Tr.*, 1871, 585; *Australian Journ. Pharm.*, 1887.) According to Augustine Henry, there are at least eleven species of trees whose products are used in China for washing purposes and probably contain saponin, which is also found to the extent of 10 per cent. in the seeds of the Chinese tea-oil tree, and is left in such large proportion in the refuse after the extraction of the oil that the "tea-seed cake" is used as a fish-poison. (*American Druggist*, 1896.) In California the *Indian Soap Root* (*Chlorogallum pomeridianum*) is much used for washing clothes: it probably contains saponin. When in diluted form saponin is irritant to all tissues, and when concentrated it kills by its local action both muscular and nervous tissue. As was first discovered by H. Köhler, when injected into the leg of the frog in minute quantity it produces not only motor weakness but a rapid loss of sensibility, so that reflex movements can no longer be caused by irritating the foot. The paralysis seems to affect especially the peripheral nerve-endings, since irritation of the nerve-trunk, although incapable of causing contraction of the muscles supplied by it, elicits pain cries and other evidences of sensibility. Muscles with which saponin comes in contact become unexcitable and pass into a condition resembling post-mortem rigidity. According to Köhler, this occurs without change in the microscopic structure, but Przybyszewski found that in the neighborhood of the injection where the saponin was abundant the muscles underwent structural changes similar to those of myositis. In the frog saponin produces not only local symptoms, but after a time wide-spread paralysis, with final arrest of the cardiac movements. Given internally to mammals it causes violent gastro-intestinal irritation, progressive loss of power, disturbance of respiration and circulation, and usually clonic and tonic convulsions, which are probably secondary to the perturbations of the cardiac and respiratory functions. Injected into the circulation in rabbits and dogs, according to the researches of Przybyszewski, it causes fall of the arterial pressure, with great disturbance of the respiration and finally cardiac arrest. According to Köhler, the action of the drug upon the heart is antagonistic to that of digitalin, so that the application of sufficient quantities of saponin to the frog's heart which has been arrested by the local application of digitalin will bring about a return of pulsations, whilst, on the other hand, digitalin is capable of putting aside cardiac arrest from saponin. The action of saponin upon the respiratory centres is very great, the injection of large doses being followed by immediate arrest of respiration, the heart continuing to beat for some time. As it exists in agrostemma seeds, saponin has several times caused death in the human species. The symptoms have been headache, vertigo, vomiting, hot skin, rapid feeble pulse, progressive muscular weakness, and finally coma. Following out the experiments of Kobert, Ulenburg and Keppler tried saponin as a local anæsthetic, but found that it was not practically convenient for use; nor were the essays of Kobert with the glucoside as an antipyretic more encouraging.

Senega appears to depend upon saponin for whatever expectorant virtues it may possess, and the use of *quillaja* bark has been strongly urged by Kobert, (See *Quillaja.*) In Germany soap root has been used as a substitute for sarsaparilla in scrofulous, venereal, and cutaneous affections, and also by Andri in the form of inspissated juice, half an ounce a day, in *gonorrhœa.* The dose of the decoction is set down as from two to four pints. For further information as to the physiological action of saponin, consult *Husemann's Pflanzenstoffe*, second edition, and *Schmidt's Jahrbücher*, Bd. xxi., 3, 13.

According to Kobert (*Gaz. Méd. de Paris*, xiv. 2, 1883), saponin of commerce is composed chiefly of two substances, *quillaic acid* and *sapotoxin.* For method of preparation, see *Therap. Gaz.*, vol. ii. 540. The quillaic acid is said to be extraordinarily poisonous, three-one-thousandths of a grain for each pound of body-weight injected into the veins of a cat being sufficient to cause death, although thirty grains administered by the mouth are safely borne.

SAPROL. *Disinfection Oil.* A mixture of crude cresols, containing pyridine bases and hydrocarbons, used for disinfecting purposes. As it is inflammable, care should be exercised in its use.

SARCOCOLLA. *Sarcocolle*, Fr. *Fleischleimgummi, Fischleimgummi*, G. A peculiar vegetable product, exuding spontaneously from various species of the genus Penæa (nat. ord. Penæaceæ), small shrubs growing at the Cape of Good Hope, in Ethiopia, Arabia, etc. It is in the form of small, roundish, irregular grains, sometimes agglutinated in masses, friable, opaque or semi-transparent, of a yellowish or brownish-red color, inodorous unless heated, when they have an agreeable smell, and of a peculiar, bitter, sweetish, and acrid taste. Sarcocolla, according to Pelletier, consists of 65·3 per cent. of a peculiar substance, considered by Dr. Thomson as holding an intermediate place between gum and sugar, and called *sarcocollin*, $C_{13}H_{23}O_6$, or pure sarcocolla, 4·6 of gum, 3·3 of a gelatinous matter having some analogy with bassorin, and 26·8 of lignin, etc. It is said to be purgative, but at the same time to produce serious inconvenience by its acrid properties. The Arabian physicians used it internally; and by the ancients it was employed as an external application to wounds and ulcers, under the idea that it possessed the property of agglutinating the flesh, whence its name.

SARRACENIA. *Side-saddle Plant. Fly-trap. Pitcher Plant. Huntsman's Cup. Water Cup. Sarracenie*, Fr., G. According to E. P. Porcher, the roots of *Sarracenia flava*, L., and *S. variolaris*, Michx., have long been used in the Southern United States in *dyspepsia*, and are tonic, laxative, and diuretic. Sheppard found it to contain lignin, coloring matter, resin, an acid salt of lime, and probably an alkaloid. Dose of tincture (℥ii to Oi), a teaspoonful; of fluid extract, from ten to twenty minims. M. Stan. Martin asserts that he has found in the root,—1, an alkaloid which he proposes to name *sarracenine;* 2, a resin; 3, a yellow coloring principle (probably identical with Schmidt's *sarracenic acid*); 4, extractive; 5, substances which constitute the framework of plants. Sarracenine is white, soluble in alcohol and ether, combines with acids to form salts, and with sulphuric acid forms handsome needles, which are bitter, and communicate this taste to its menstrua. (*Ann. de Thérap.*, 1866, 73.) E. Schmidt, however, found no alkaloid, but discovered *sarracenic acid.* (*A. J. P.*, 1872, 213.)

SASSA GUM. This name has been applied by Guibourt to a gum, occasionally brought into market from the East, and answering to Bruce's description of the product of a tree which he calls *sassa.* According to Guibourt's description, it is in mammillary masses, or in convoluted pieces resembling an ammonite, of a reddish color and somewhat shining surface, and more transparent than tragacanth. Its taste is like that of tragacanth, but slightly acrid. When introduced into water it becomes white, softens, and swells to four or five times its original bulk; but it preserves its shape, neither, like tragacanth, forming a mucilage, nor, like Bassora gum, separating into distinct flocculi. It is rendered blue by iodine.

SASSY BARK. *Mancona Bark. Saucy Bark. Ecorce de Mançoine*, Fr. *Manconarinde*, G. This bark is interesting chiefly from its employment by the natives of Western Africa as an ordeal in their trials for witchcraft or sorcery. This bark was first studied by C. A. Santos (*A. J. P.*, 1849, xxi. 97), and subsequently by Procter (*Ibid.*, xxiii. 301, xxiv. 195), who proposed the name of *Erythrophleum judiciale* for the tree yielding it. The tree had, however, been previously described under two specific names, having been noted in Hooker's *Niger Flora* (p. 329) as the *Erythrophleum guineense* of Don, and being also the *Fillæa suaveolens* of Guillemin and Perottet's *Flora of Senegal.* It is a large tree with spreading branches, doubly pinnated leaves, flowers in spike-like racemes, and leguminous fruit. The bark is in pieces more or less curved, with or without epidermis, in the former case somewhat fissured externally, of a dull red color diversified by whitish spots, brittle, presenting when cut transversely numerous fawn-colored spots surrounded by reddish-brown tissue, nearly inodorous, and of an astringent taste.* Gallois and Hardy obtained the poisonous principle *erythrophleine* by making an alcoholic extract of the bark, exhausting this with water, evaporating, rendering this extract alkaline with ammonia, and treating with acetic ether. The alkaloid is a colorless, crystalline solid, soluble in water, acetic ether, alcohol, and amylic alcohol, insoluble in chloroform, benzin, and ether. In contact with sulphuric acid and black manganese oxide, a violet color (less intense than that produced with strychnine) is developed. Harnack and Zabrocki (*Arch. f. Exper. Path.*, xv. 404) also prepared erythrophloeïne, and by the action of hydrochloric acid upon it obtained an acid they call *erythrophloeïc acid*, and a volatile alkaloid they call *mançonine.* The bark yields its virtues to water.

According to the observations of Savage, made in Africa (*Charleston Med. Journ.*, 1859), sassy bark produces in the natives a feeling of constriction in the fauces, attended by prickling, and followed by numbness, with, after a toxic dose, stricture across the brow, severe pain in the head, coma, and death. The physiological action of erythrophleine has been studied by various observers, especially by E. Harnack and R. D. Zabrocki,

* A comprehensive description of sassy bark is given in the *Commentar zur oesterreichischen Pharmacopœia*, 1880, by Prof. Vogel; while in the *Résumé de la Matière Médicale et Toxicologique Coloniale*, by Messrs. Corre and Lejuanne, the plant, fruits, seeds, etc., are carefully illustrated.

Gallois and Hardy, and Lauder Brunton, with results which are fairly concordant. It has a very pronounced action upon the circulation, causing a slow strong pulse, with a rise in the arterial pressure; phenomena which are certainly in great part due to the direct action upon the ganglionic structure or muscular fibre of the heart itself, but which are also seemingly in part produced by a stimulating influence upon the muscle-fibres or nerves in the walls of the arterioles. The action, therefore, of erythrophleine would seem to be very close to that of the digitalis principles. Purging was also noted as the result of an increased peristalsis, thought to be due to the local action of the poison. Vomiting is believed by Lauder Brunton to be the result of an influence upon the nerve-centres, because it occurs when the alkaloid is given hypodermically. In fatal poisoning in the lower animals, convulsions are pronounced, and the respiration is also markedly affected. In 1888 Dr. L. Lewin asserted erythrophleine to be a powerful local anæsthetic, whose action is more pronounced than that of cocaine. His paper gave rise to an extraordinary controversy, the outcome of which appears to be that, although the alkaloid is possessed of not very active anæsthetic powers, it is for various reasons practically not useful. (See 17th ed. *U. S. D.*, p. 1739.) A solution of the strength of one-tenth of one per cent. is used as an application to the cornea.

Germain Sée asserts (*La Méd. Moderne*, Dec. 1891) that, although sassy bark does not act well upon the heart, it gives great relief in *dyspnœa*, the number of respirations being lessened and the inspirations being extraordinarily increased in size. He gave of the alkaloid from $\frac{1}{10}$ to $\frac{1}{12}$ of a grain (0·0015–0·002 Gm.); of the extract, from $\frac{2}{10}$ to $\frac{3}{10}$ of a grain (0·015–0·02 Gm.).

SATUREIA HORTENSIS. L. *Summer Savory.* S. Montana. *Winter Savory. Sarriette*, Fr. *Saturei, Bohnenkraut*, G. Annual labiate plants, resembling thyme in odor and flavor, growing spontaneously in the south of Europe, and cultivated in our gardens as culinary herbs.

SAURURUS CERNUUS. L. *Lizard's Tail.* (Nat. ord. Saururaceæ.) D. L. Phares, of Newtonia, Miss., considers this indigenous swamp plant "laxative, antispasmodic, sedative, and slightly astringent;" useful in irritation of the kidneys, bladder, prostate, and urinary passages generally. The dose of the strong infusion was, with the plant either fresh or dried, from one to four ounces every fifteen or thirty minutes, or three or four times a day. (*A. J. P.*, 1867, 468.)

SAW PALMETTO. *Serenoa Serrulata*, Hook. f. The fruit of this palm, growing in the Southeastern United States, was investigated by Coblentz (*Proc. New Jersey Pharm. Assoc.*, 1895, 45). He found in the pulp of the berries a volatile oil, fixed oil, fat, an alkaloid, resin, dextrin, and glucose; the seeds contained 12·12 per cent. of fixed oil. Sieker (*Pharm. Rev.*, 1897, 113) examined the fixed oil: the sp. gr. was 0·9138, and it was soluble in alcohol, ether, and benzin. It is reported sedative, diuretic, tonic, and expectorant, and is used in *phthisis* and *chronic bronchitis*, also in *sexual impotence*. Dose of the fluid extract, from one to two fluidrachms (3·69–7·4 C.c.).

SAXIFRAGA. Garreau and Machelast have isolated from different species of *Saxifraga* (*S. cordifolia*, Haw. (now *S. crassifolia*, L.), and *S. crassifolia*, L. and others) a crystallizable bitter substance, *bergenin*. It is obtained by boiling the stems of the plants with absolute alcohol, after the tannin has been removed by ether. It crystallizes in alcohol, has a bitter taste, melts at 140° C., and burns up completely at 300° C. It is soluble in 167 parts of 90 per cent. alcohol and in 830 parts of water, but is more soluble in these liquids at a boiling temperature; it is faintly acid to litmus, and is not changed by treatment with dilute sulphuric or hydrochloric acid, but by dilute nitric acid is converted into oxalic acid. Concentrated sulphuric acid decomposes it. Its formula is given as $C_6H_3O_3,H_2O$. Bergenin is asserted to be intermediate in its action between salicylic acid and quinine. (*Arch. d. Pharm.*, 1881, 293.) The rhizome of the *Saxifraga ligulata*, Wall., which is used in India in *dysentery*, has been found by David Hooper to contain about 16 per cent. of gallic and tannic acids, but no other active principles. (*P. J. Tr.*, Aug. 1888.)

SCHINUS MOLLE. L. (Nat. ord. Anacardiaceæ.) The *pepper-tree* of South America yields a berry the size of a pea, having a flavor of a mixture of pepper and fennel. It has been introduced as a shade-tree in Southern California. (*A. J. P.*, 1896, 215.) Schimmel & Co. examined the volatile oil distilled from the berries; it had the sp. gr. 0·850, the odor of phellandrene, and was soluble in alcohol. (*Pharm. Rev.*, 1897, 114.) It has been used successfully in *gonorrhœa* as a substitute for cubebs. The leaves, bark, and gum-resinous exudation have been employed medicinally. (See *A. J. P.*, 1866, 1885, 1890; also *P. J. Tr.*, 1887.)

SCHLEICH'S ANÆSTHESIA MIXTURE. In 1895 Schleich proposed the use of an anæsthetic mixture based upon the theory that the ideal anæsthetic should have a boiling point as near as possible to the temperature of the human body, so that elimination should take place from the lungs as rapidly as possibly, with consequent immediate awakening from unconsciousness. Schleich's mixtures, three in number, are,—

Mixture No. 1. Boiling point, 100·4° F. Chloroform, 45 C.c.; petrolic ether, 15 C.c.; sulphuric ether, 180 C.c.

Mixture No. 2. Boiling point, 104° F. Chloroform, 45 C.c.; petrolic ether, 15 C.c.; sulphuric ether, 150 C.c.

Mixture No. 3. Boiling point, 107·6° F. Chloroform, 30 C.c.; petrolic ether, 15 C.c.; sulphuric ether, 80 C.c.

Of these mixtures No. 1 is the most evanescent and produces the briefest anæsthesia, whilst No. 3 is the most permanent in its action.

The incorrectness of the assertion of Schleich, that benzin is a neutral diluent, has been demonstrated by Horatio C. Wood, Jr., in a series of experiments (*Phila. Med. Journ.*, April, 1899), in which he proved that benzin acts both upon the heart and the vaso-motor system as a paralyzant, and that its effect upon the respiratory centre is even more powerful, while its anæsthetic influence is exceedingly feeble. It would appear, therefore, that the use of Schleich's mixture is attended by more danger than is that of either chloroform or ether, a conclusion which seems to be borne out by the analysis of about one thousand reported cases made by Horatio C. Wood, Jr.

SCOLOPENDRIUM SCOLOPENDRIUM. (L.) Karst. *Asplenium Scolopendrium.* Linn. *Harts-tongue.* The leaves of this fern,

which is indigenous both in Europe and America, have a sweetish, mucilaginous, and slightly astringent taste, and, when rubbed, a disagreeable oily odor. They were used as a deobstruent in visceral affections, as an astringent in *hemorrhages* and fluxes, and as a demulcent in pectoral complaints.

SCROPHULARIA NODOSA. L. *Figwort. Scrofula Plant. Scrofulaire*, Fr. *Kropfwurz, Knotenwurz*, G. (Nat. ord. Scrophulariaceæ.) This European plant has become abundantly naturalized in America. Its leaves have when fresh a rank fetid odor, and a bitter, somewhat acid taste; but these properties are diminished by drying. Water extracts their virtues, forming a reddish infusion, which is blackened by ferric sulphate. For histological study of root, see *P. J. Tr.*, 1896. Walz has obtained from them two proximate principles, which he names respectively *scrophularin* and *scrophularosmin*. (Mayer, *A. J. P.*, 1863, 295.) Figwort leaves were formerly considered tonic, diuretic, diaphoretic, discutient, anthelmintic, etc.; useful in *scrofula* and as a local application in *hemorrhoids*. Van der Moer (*P. J. Tr.*, 1896) affirms that the seeds are toxic, belonging to the digitalis group.

SECALE CEREALE. L. *Rye.* (Nat. ord. Gramineæ.) Syria, Armenia, and the southern provinces of Russia have been severally indicated as the native country of rye. The plant is now cultivated in all temperate latitudes. The grains consist, according to Einhof, of 24·2 per cent. of envelope, 65·6 of flour, and 10·2 of water. The average composition of rye as a cereal may be thus stated: fat, 1·43 per cent.; starch, 61·87 per cent.; sugar (as sucrose), 4·30 per cent.; albumen (insoluble in alcohol), 9·78 per cent.; nitrogenous matter (soluble in alcohol), 5·09 per cent.; cellulose, 3·23 per cent.; mineral matter, 1·85 per cent.; moisture, 12·45 per cent. (Sadtler, *Ind. Org. Chem.*, 162.) Rye flour has been much used, in the dry state, as an external application to *erysipelatous inflammation* and other eruptive affections, the burning and unpleasant tingling of which it tends to allay, while it absorbs the irritating secretions. In the form of mush it is an excellent laxative article of diet, and, mixed with molasses, it may be given with great advantage in *hemorrhoids* and *prolapsus ani*, connected with *constipation*. Rye carbonized by heat, with exclusion of the air, has been highly recommended as a tooth-powder.

SEDATIN, *Para-valerylphenetidine*, is made by the action of phenetidine hydrochlorate upon sodium valerate; it occurs in fine crystals. It is soluble in hot alcohol, sparingly soluble in ether, chloroform, and benzin. It is said to act like antipyrin.

SEDUM ACRE. L. *Biting Stone-crop. Wall Pepper. Small Houseleek. Mossy Stone-crop. Joubarbe âcre, Poivre des Murailles*, Fr. *Mauerpfeffer, Steinkraut*, G. (Nat. ord. Crassulaceæ.) This European plant has escaped to some extent from the gardens and grows wild in New England. Taken internally it vomits and purges, and applied to the skin produces inflammation and vesication. The fresh herb and the expressed juice have been used as an antiscorbutic, emetic, cathartic, and diuretic, and have been applied locally to old *ulcers*, *warts*, and other excrescences. Other species are less acrid, and are even eaten as salad in some parts of Europe. Such are *Sedum rupestre*, L., and *S. album*, L. *S. telephium*, L., was formerly employed externally to cicatrize wounds, and internally as an astringent in *dysentery* and *hæmoptysis*, and is still esteemed by the common people in France as a vulnerary. M. Ernst Mylius found in 100 parts of *Sedum acre* 2·2 parts of a soft, not acid resin, 12·80 parts of uncrystallizable sugar, and 12·40 parts of a soft acid resin, besides an alkaloid and inert substance. (*Journ. de Pharm.*, 4e sér., xvii. 81.)

SELENIUM. Se. 78·87. This widely distributed element, discovered by Berzelius in 1817, belongs to the sulphur group, and its compounds occur in nature associated with sulphur compounds. It is most conveniently extracted from the lead chamber deposits of the sulphuric acid works. The physiological actions of the compounds of this metal have not been widely studied, but Chabrié and Sépicque (*Compt.-Rend.*, cx.) have shown that selenious acid is an irritant poison.

SELINUM PALUSTRE. L. (Now *Peucedanum palustre*, Moench.) *Marsh Parsley. Persil de Marais*, Fr. *Radix Olsnitii. Sumpfsilge, Elsenich*, G. The root of this European umbellifer is, when dried, of a brown color externally, having a strong aromatic odor, and an acrid pungent, aromatic taste. Peschier found it to contain a volatile oil, a fixed oil, and a peculiar acid which he calls *selinic*. It has been used for *epilepsy* in Russia. Dose, from twenty to thirty grains (1·29–1·94 Gm.) thrice daily, rapidly increased to four times the amount. (*Journ. de Pharm.*, 1859.)

SEMPERVIVUM TECTORUM. L. *Common Houseleek. Grande Joubarbe*, Fr. *Hauswurz, Dachwurz*, G. (Nat. ord. Crassulaceæ.) In Europe the bruised recent leaves of this plant are employed as a cooling application to burns and other external inflammations. The juice is said to cure *warts*.

SENECIO. Various species of this genus of the nat. ord. Compositæ are believed to possess medical properties. *Senecio vulgaris*, L., *Common Groundsel, Seneçon*, Fr., *Kreutzkraut, Jacobskraut*, G., an annual European plant, introduced into this country, and growing in cultivated grounds, is used by the common people in *amenorrhœa* and, when bruised, as an external application to painful swellings and ulcers. A. Grandval and H. Lajoux (*Union Médicale du Nord-est*, xix. 1895) state that they have separated from it two crystalline alkaloids,—*senecionine*, $C_{18}H_{26}NO_6$, and *senecine*. The same investigators (*Ibid.*) have found the two alkaloids present in smaller quantity in the European species, *Senecio jacobœa*, L. Wiet (*Ibid.*) finds that senecionine paralyzes both the motor and sensory fibres of the peripheral nerves.

The North American species, *S. aureus*, L., or *ragwort*, which is said by Schoepf to have been a favorite vulnerary with the Indians, is believed by the "eclectics" to be an effective emmenagogue and diuretic, also having the power of regulating both the uterine and renal functions when in any way disordered. Wm. Murrell (*Med. Press and Circular*, April, 1894) classes senecio with pulsatilla in therapeutic action. In doses of a fluidrachm three or four times a day the fluid extract has been highly commended by F. Gundrum in the treatment of *hæmaturia, hæmoptysis*, and other internal hemorrhages.

The rhizomes of the Mexican species, *Senecio grayanus*, Hemsl., and *Senecio cerviariæfolius*, Hemsl., constitute *maturin*, the plants being known as *mata-*

rique, *maturin*, or *guereña*. They produce rise of temperature, dilatation of the pupil, and violent tetanic spasms. Henckel states that they contain a glucoside resembling digitalin. (*A. J. P.*, Jan. 1891; also *Nouveaux Rem.*, 1888, and *P. J. Tr.*, March, 1889.) *Senecin* of the "eclectics" is a preparation made by precipitating the tincture with water, and must not be confounded with the pure active principle. The whole plant is used in decoction or infusion, which may be taken freely.

SETHIA ACUMINATA. The juice of this Ceylon plant or the powdered leaves—dose, fifteen grains (0·9 Gm.)—are affirmed to be an efficient vermifuge. (*P. J. Tr.*, April 7, 1883.)

SHEPHERDIA ARGENTEA. Nutt. (Now *Lepargyrea argentea*, Greene; also (Nutt.) Greene.) *Buffalo Berry. Bull. Berry. Grains de Bœuf*, Fr. The acidulous fruit of this plant, of the nat. ord. Elæagnaceæ, produced in great profusion in the region of the upper Missouri, is largely used as an article of food. According to Henry Trimble, they contain a little more acid than currants. (*A. J. P.*, Dec. 1888.)

SIDA. *Sida rhombifolia.* L. *Queensland hemp* (nat. ord. Malvaceæ), *Jelly leaf*, is largely used in Australia as a demulcent. It contains a large quantity of mucilage. *Sida floribunda*, H. B. K. (now *S. paniculata*, L.), of Peru, which also contains a large quantity of mucilage, is said by Dr. M. Martinet to be a very active vermifuge, owing its powers, probably, to the extremely minute but very resisting spines which cover its leaves, the part used.

SIEGESBECKIA ORIENTALIS. L. (Nat. ord. Compositæ.) This plant is used in the Mauritius Islands in *syphilis*, *leprosy*, and various skin diseases. A white, crystalline principle, *darutyne*, has been discovered in it by M. L. Auffray. (*P. J. Tr.*, vol. xvi. 1047; also *Brit. Med. Journ.*, June 25, 1887.)

SIENNA. *Terra di Sienna.* An argillaceous mineral, compact, of a fine texture, very light, smooth, and glossy, of a yellowish-brown or coffee color, leaving a dull orange trace when moistened and drawn over paper. By calcination it assumes a reddish-brown color, and is then called *burnt sienna*. In both the raw and burnt states it is used in painting. The best sienna is brought from Italy, but an inferior kind is found in England.

SILENE VIRGINICA. L. (Nat. ord. Caryophyllaceæ.) *Catchfly. Wild Pink.* The wild pink of West Virginia and the Carolinas was considered by the Indians poisonous, and by Prof. Barton an anthelmintic.

SILEX, PULVERIZED. SILEX CONTRITUS. *Lond. Silicic Acid.* For mechanical purposes, in the making of aromatic waters, etc., the London Pharmacopœia formerly recognized under the name of *Silex Contritus* powdered quartz; but at present magnesium carbonate is universally employed. For details, see 17th ed. *U. S. D.*, p. 1741.

Pulverized silex is a harsh, white, tasteless powder, insoluble in water and most other solvents. Its sp. gr. is 2·66. In composition it is a silicic oxide, SiO_2. *Silicon* is a non-metallic element, which has been obtained in three allotropic states, called amorphous, graphitoidal, and octahedral silicon; the first corresponding to charcoal, the second to graphite, and the third to diamond. The octahedral crystallizes like diamond with curved facets, is hard enough to scratch glass but not topaz, and has the sp. gr. 2·49. Pure *silica* is easily prepared by acidulating commercial solution of sodium silicate with hydrochloric acid, heating and evaporating, and washing the precipitated silica.

SILPHIUM LACINIATUM. L. *Polar Plant.* (Nat. ord. Compositæ.) The *rosin weed*, or *compass plant*, of Ohio, yields an oleoresin, which is said to be used in making chewing gum. (*A. J. P.*, 1881, 487.)

SIMARUBA. Under this name the U. S. P. formerly recognized the bark of the root of *S. officinalis*, D. C. (now *S. amara*, Aubl.). *Ecorce de simarouba*, Fr. *Simarubarinde*, *Ruhrrinde*, G. *Corteccia di Simaruba*, It. *Corteza de Simaruba*, Sp. (Nat. ord. Simarubeæ.) It is a tree of considerable height and thickness, having alternate branches, with a bark which in the old tree is black and somewhat furrowed, in the young is smooth, gray, and marked here and there with broad yellow spots. The leaves are alternate and abruptly pinnate, with a naked petiole, to which the leaflets are alternately attached by short footstalks. The leaflets are nearly elliptical, on the upper surface deep green, on the under whitish. The flowers are yellow, diœcious, and in long axillary panicles. According to Dr. Wright, the male and female flowers in Jamaica are never found on the same tree.

The tree is found in the West Indies and Guiana. In Jamaica it is called the *mountain damson*. *Simaruba amara* of Aublet, which grows in Guiana, and has generally been considered identical with *Quassia Simaruba*, L., is believed by Hayne to be a distinct species, the Jamaica plant having diœcious, while this has apparently monœcious flowers. The bark of the root is the part employed, the wood itself being nearly tasteless and inert.

The bark of the root of *S. officinalis*, Macf. (found in Jamaica, St. Domingo, Bahama Islands, Panama, Guatemala, and Florida), and *S. amara*, Aubl. (found in French Guiana and the islands of Dominica, Martinique, St. Lucia, St. Vincent, and Barbadoes in the West Indies), contain in the middle bark quantities of resin. A decoction of the bark and leaves of *S. versicolor*, St.-Hil. (Cortex Paraibæ), is employed in Brazil as an antidote for snake-bites and in the treatment of *syphilis* and *tapeworm*; the powder is used against vermin.

Simaruba bark is in long pieces, some inches in breadth, folded lengthwise, light, flexible, tenacious, very fibrous, externally of a light brownish-yellow color, rough, warty, and marked with transverse ridges, internally of a pale yellow. It is without smell, and of a bitter taste. It readily imparts its virtues, at ordinary temperatures, to water and alcohol. The infusion is at least equally bitter with the decoction, which becomes turbid as it cools. Its constituents, according to M. Morin, are a bitter principle identical with *quassin*, $C_{10}H_{12}O_3$; a resinous matter, a volatile oil having the odor of benzoin, malic acid, gallic acid in very minute proportion, an ammoniacal salt, calcium malate and oxalate, some mineral salts, ferric oxide, silica, ulmin, and lignin. Simaruba possesses the same tonic properties as other simple bitters. In large doses it is said to purge and vomit. On account of its difficult pulverization, it is seldom given in substance. The best mode of administration is by infusion. The dose is from a scruple to a drachm (1·296–3·88 Gm.).

SIMULO. The dried fruit of one of the *Capparisсorriaceæ* has been highly recommended by reputable clinicians as a palliative in *epilepsy;* also in *chorea.* (See *Therap. Gaz.*, 1888, 1889, and *Therap. Monatssch.*, Aug. 1888.)

SIROLIN. A preparation of beech tar containing a large proportion of guaiacol. It has been used in the same class of pulmonic diseases as creosote. The adult dose is one teaspoonful (3·8 C.c.).

SISYMBRIUM OFFICINALE. Scop.; also (L.) Scop. *Erysimum officinale.* L. *Hedge Mustard. Herbe aux chantres, Tortelle,* Fr. *Wildersenf, Hederich,* G. (Nat. ord. Cruciferæ.) This annual, growing in Europe and the United States, is said to be diuretic and expectorant, and has been recommended in chronic *coughs, hoarseness,* and ulceration of the mouth and fauces. The juice of the plant may be used mixed with honey or sugar, or the seeds may be taken in substance. *Sisymbrium sophia,* or the *flax weed,* was formerly official. It is of a pungent odor when rubbed, and of an acrid biting taste. W. Zopf attributes its poisonous qualities to a volatile alkaloid. (*Zeit. f. Nat. Pharm. Central.*, 1894, 494.) The herb has been used externally in indolent ulcers, and the seeds internally in worms, calculous complaints, etc. *Sisymbrium murale,* L. (*Diplotaxis muralis,* D. C.), has been used in France in *scurvy, scrofula,* and other cachectic affections, especially associated, in the form of a syrup, with potassium iodide. (*Ann. de Thérap.*, 1863, 126.)

SIUM NODIFLORUM. L. (Now *Apium nodiflorum,* Reichb. f.) *Water parsnip.* A perennial umbelliferous, aquatic European plant, growing also in the southern section of the United States. It is commonly considered poisonous; but the fresh juice has been used by Withering and others, in the dose of three or four ounces every morning, for scrofulous *lymphadenitis* and obstinate *skin diseases. Sium latifolium* of American authors (now *S. acutæfolium,* Gmel.), which grows in Europe and the United States, particularly along the watercourses of the valleys of the Pacific slope, and is the *hemlock water-parsnip* of this country, is positively asserted to be poisonous. A. R. Porter and N. Rogers (*A. J. P.*, 1876, 348, 483) found in it an active resinous body, toxic to animals. *S. sisarum,* L., or *skirret,* a plant of Chinese origin, cultivated in Europe, has a sweetish, somewhat aromatic root; it is employed as a salad, and is supposed to be a useful diet in chest complaints.

SKIN VARNISHES. Prof. Unna has arranged a series of preparations for forming thin coverings on the skin. We reproduce the most important formulas.

Bassorin Varnish. The pure bassorin basis is obtained, according to Elliot, by filtering tragacanth mucilage (15 to 100) in a filter heated by steam, evaporating, and mixing with glycerin. A similar basis may be prepared by stirring five parts powdered salep with ninety-five parts cold water until a smooth mucilage is obtained, then heating for half an hour on the steam-bath. The salep basis contains less bassorin, but more starch.

Casein Varnish. The casein obtained by coagulating skimmed milk with rennet at a temperature of from 35° to 40° C. is washed and dried until it forms a yellowish-white sandy powder soluble in alkaline solution. In preparing the casein varnish this casein is dissolved by means of borax. For 20 parts casein 2·5 parts borax and 77·5 parts water furnish a rapidly drying uniform covering material. The alkaline characters of the borax are masked by the casein. Admixtures of heavy pulverulent substances readily settle out of this basis, and it is requisite to distribute them by shaking. A varnish of casein and glycerin is prepared by dissolving the casein in 3 or 3·5 parts of ammonia, adding a quantity of glycerin equal in weight to the casein, and heating to drive off the ammonia. The resulting mass mixed with twice its weight of boiling water gives an excellent permanent emulsion.

Amber Varnish. Made by dissolving a mixture of amber and turpentine in alcohol. It must not be used as a vehicle for the application of zinc oxide.

Castor Oil and *Shellac Varnish.* With 1 part shellac, 1½ parts castor oil, and 3 parts alcohol, a varnish is obtained which forms a good flexible covering easily removed by alcohol.

Canada Balsam and *Collodion Varnish.* Sixteen parts collodion with 1 part Canada balsam gives a material suitable for the application of pyrogallol, and it can be easily removed by alcohol.

Castor Oil and *Collodion Varnish.* Eight parts collodion and 1 part castor oil.

Lead Ricinoleate Varnish. One part lead oxide heated with 1½ parts castor oil to saponification, and mixed with 2 parts absolute alcohol, gives a good skin varnish.

Chrysarobin Amber Varnish. One part chrysarobin and 20 parts amber dissolved in turpentine.

Pyrogallol Shellac Varnish. One part pyrogallol, 1 part castor oil, 5 parts shellac, and 15 parts absolute alcohol.

Salicylic Acid, Canada Balsam, and *Collodion Varnish.* One part Canada balsam, 10 parts collodion, and 3 parts salicylic acid.

Zinc Oxide, Castor Oil, and *Collodion Varnish.* Two parts zinc oxide, 2 parts castor oil, and 16 parts collodion.

Zinc and *Lead Ricinoleate Varnish.* Five parts lead ricinoleate, 8 parts zinc oxide, 8 parts absolute alcohol, and, lastly, 1 part each of collodion and ether.

Ichthyol Borax Casein Varnish. Five parts sodium ichthyolate and 15 parts borax casein varnish.

Sulphur Glycerin Casein Varnish. Five parts sulphur and 15 parts glycerin and casein varnish.

Zinc Oxide Salepbassorin Varnish. Two parts zinc oxide and 18 parts salepbassorin varnish.

Zinc Ichthyol Tragacanth Bassorin Varnish. One part sodium ichthyolate, 2 parts zinc oxide, and 17 parts tragacanth bassorin varnish.

SMALT. *Smalts. Azure.* When the impure cobaltic oxide, obtained by roasting the native arsenide of that metal, is heated with sand and potassa, the mixture melts, and a beautiful blue glass results, which, when reduced to powder, forms smalt or azure. It is used chiefly in painting, and for coloring glass and porcelain.

SODII OLEAS. *Eunatrol.* Sodium oleate is a white powder, dissolving freely in water and alcohol. According to F. Blum (*Der ärztl. Praktiker,* 1897), it has a very powerful action upon the liver, making it very useful in cases of *gall-stones* and chronic *hepatic torpor.* Dose, from thirty to eighty grains (1·9–5·2 Gm.) daily in capsules.

SODII SULPHOBENZOAS. $C_6H_4(NaSO_3)COONa$. M. Heckel (*Compt.-Rend.*, cv. 896) asserts that sodium sulphobenzoate is a non-poison-

ous antiseptic, superior to carbolic acid, and equal to mercurial solution in the antiseptic treatment of wounds: strength of solution about fifty grains in a quart.

SODII SULPHORICINICUM. *Sodium Sulphoricinate. Solvin. Polysolve.* $C_{18}H_{33}O_2OSO_3$. This is a clear yellow-brown syrup-like liquid, having a feeble alkaline reaction, which is used for the purpose of dissolving phosphorus, iodine, phenol, resorcin, naphtalin, and other substances making strongly antiseptic solutions. Of these preparations the only one of importance is the *phenol sodium-sulphoricinicum*, often incorrectly known as *phenol sulphoricinicum*. It is a yellow-brown, thick, syrupy liquid, strongly antiseptic and distinctly caustic. It is put upon the market in two forms, one containing 25 the other 30 per cent. of phenol. First recommended by T. Heryng (*Therap. Monat.*, 1896) as a local caustic application to *papilloma* and *ulcers* in the nasal and laryngeal passages, or diluted in various forms of chronic inflammation of the mucous membrane of the nose and larynx. These statements have been confirmed by various laryngologists. Przedborski finds it of very great service both in *rhinitis atrophica* and *hypertrophica*.

SODII VALERIANAS. *Sodium valerianate* was dismissed from the U. S. Pharmacopœia in 1870, from the British Pharmacopœia in 1898. The British process of its preparation is as follows: "Take of Amylic Alcohol *four fluidounces* [Imperial measure]; Bichromate of Potassium *nine ounces* [avoirdupois]; Sulphuric Acid *six fluidounces and a half* [Imp. meas.]; Solution of Soda *a sufficiency;* Water *half a gallon* [Imp. meas.]. Dilute the Sulphuric Acid with ten fluidounces of the Water, and dissolve the Bichromate of Potassium in the remainder of the Water with the aid of heat. When both liquids are cold, mix them with the Amylic Alcohol in a retort or flask, with occasional brisk agitation, until the temperature of the mixture has fallen to about 90° F. (32·2° C.). Connect with a condenser, and distil until about half a gallon of liquid has passed over. Saturate the distilled liquid accurately with the Solution of Soda, remove any oily fluid which floats on the surface, evaporate till watery vapor ceases to escape, and then raise the heat cautiously so as to liquefy the salt. When the product has cooled and solidified, break it into pieces, and immediately put it into a stoppered bottle." *Br.* 1885.

The above process consists of two steps: first, the artificial formation of valerianic acid, and, second, the saturation of this acid with caustic soda. By distilling fusel oil with a mixture of sulphuric acid and potassium bichromate, valerianic acid is formed, and passes over with water. The change is effected by the oxidizing agency of the chromic acid of the bichromate; for when the amyl alcohol of the fusel oil loses two atoms of hydrogen by oxidation, and gains one of oxygen, it is converted into valerianic acid: thus, $C_5H_{12}O + O_2 = C_5H_{10}O_2 + H_2O$. (See *Potassii Bichromas* and *Alcohol Amylicum.*) The distillate, by exact saturation with the solution of caustic soda, is converted into a solution of sodium valerianate, which, by the application of heat until the water is driven off and the residual matter is partially liquefied, furnishes, on cooling, the concrete salt. The small portion of oil that floats on the surface of the solution is amyl valerianate, $C_5H_{11},C_5H_9O_2$.

Properties. Sodium valerianate is a deliquescent, very soluble salt, in snow-white masses, having the disagreeable odor of valerianic acid, and a taste at first styptic, but afterwards sweetish. When heated to 140·5° C. (285° F.), it fuses without loss of acid, and upon cooling concretes into a white solid. The salt, as officially ordered, is in the form produced by fusion. Its formula is $NaC_5H_9O_2$. It is little used medically, having been originally introduced into the Dublin Pharmacopœia in 1850 for the sole purpose of forming, by double decomposition, iron, quinine, and zinc valerianates. It may, however, be given as a nervous stimulant in the dose of from one to five grains (0·065–0·33 Gm.).

SODIUM AND SILVER HYPOSULPHITE. *Sodii et Argenti Hyposulphis.* This double salt may be prepared by dissolving freshly precipitated silver oxide in a solution of sodium hyposulphite and evaporating the solution. It is in the form of minute crystals of the formula $2Na_2S_2O_3 + Ag_2S_2O_3$, very soluble in water, but insoluble in alcohol, and possessing a very sweet taste. Its solution, protected from the light, undergoes no change, and, when quite pure, does not discolor the skin or linen. M. Delioux states that this salt acts locally like silver nitrate, but more mildly: for *gonorrhœa*, one or two parts in two hundred of water. (*Brit. and For. Medico-Chir. Rev.*, 1853.)

SODIUM BORO-SALICYLATE is made by heating 125 parts of boric acid, 320 parts of sodium salicylate, and 700 parts of water in a flask until a syrupy liquid is produced; this solidifies on cooling, yielding a white product. It dissolves in water. It is used as an antiseptic and preservative.

SODIUM CINNAMATE. $C_6H_5CH,CHCO_2Na$. A white, crystalline powder, soluble in water. It is used in 5 per cent. sterilized solution, internally and hypodermically in the treatment of *tuberculosis*.

SODIUM CITRATE. *Sodii Citras.* $2C_6H_5Na_3O_7 + 11H_2O$. This salt may be formed by saturating a solution of citric acid with sodium bicarbonate, evaporating the liquid, and setting it aside to crystallize. It is a white salt, crystallized in rhombic pyramids, and having a saline taste without any bitterness. Sodium citrate has been proposed by Guichon, of Lyons, as a pleasant purgative, having properties similar to those of magnesium citrate. Dose, as a cathartic, from ten to fourteen drachms (38·8–54·4 Gm.).

SODIUM ETHYLATE. *Ethylate of Sodium. Caustic Alcohol.* C_2H_5NaO. This preparation was introduced by B. W. Richardson, of England, as a caustic when specially indicated. He makes it by adding sodium in small pieces gradually to absolute alcohol, kept at a temperature of 10° C. (50° F.); hydrogen is evolved, and when, owing to the formation of the ethylate, the reaction slackens, the liquid is to be carefully heated to 37·7° C. (100° F.). Sodium is now cautiously added until the reaction ceases; the liquid is now cooled to 10° C. (50° F.), and the same quantity of absolute alcohol added as was used in the beginning. (*P. J. Tr.*, 1878, 485.) Sodium ethylate is a white powder, frequently having a brownish tinge, dissolving in water with a hissing sound, having the property of splitting into alcohol and caustic soda upon contact with even a small quantity of water or moist living tissue: $C_2H_5NaO + H_2O = C_2H_5HO + NaHO$.

Sodium ethylate does not appear to be of any value as an internal remedy. When, however, it comes in contact with moist tissue, owing to the liberation of its sodium, it acts as a very speedy and powerful caustic. It should always be used in alcoholic solution, and applied by means of a glass rod. It is said to cause very little pain, and has been especially employed for the destruction of *nævi*. (*London Lancet*, Nov. 1878.) Richardson states that it should always be kept in glass-stoppered bottles, in a cold place, as he has known it to explode when placed in warm situations. Gamberini and Monari (*Rev. de Thérap.*, 1892) assert that the 20 per cent. liniment made with olive oil, well rubbed in daily, will usually cure *psoriasis* in twenty days, and that the 10 per cent. watery solution is very valuable in the treatment of *lupus erythematosus*, applied after curetting.

SODIUM NITROPRUSSIDE. $Na_2Fe(CN)_5NO$. This is the most interesting of a series of salts, discovered by Dr. Playfair, called *nitroprussides*, which are produced, for the most part, by saturating *nitroprussic acid*, formed by the action of nitric acid on potassium ferrocyanide, with different bases. The sodium salt is best obtained by the process of A. Overbeck, as follows. Dissolve four parts of powdered potassium ferrocyanide, contained in a flask, in five and a half parts of commercial nitric acid, diluted with an equal weight of water. After the action is completed, which generally occupies about ten minutes, and is accompanied by a copious evolution of gases, heat the resulting coffee-brown liquid in a water-bath, until a drop of it gives a dingy green instead of a blue precipitate with a solution of ferrous sulphate. Then allow the liquid to cool; whereupon the larger part of the potassium nitrate generated will be deposited in crystals. Pour off the green mother-liquor from these, and separate the remaining potassium nitrate by repeated concentrations. Next neutralize the liquid, while heated in a water-bath, with sodium carbonate, taking care to add the carbonate so long only as a pure blue precipitate is produced. Lastly, filter the solution, and set it aside for the formation of crystals, which must be washed with water, and dried between blotting-paper. (*Chem Gaz.*, 1853, 271.) This salt is in the form of large, ruby-colored, prismatic crystals, very much resembling those of potassium ferricyanide. It is soluble in two and a half parts of cold water, and in a less quantity of hot water. Its solution, exposed to sunshine, is decomposed, with evolution of nitric oxide gas, and deposition of Prussian blue, at the same time acquiring a green color. Sodium nitroprusside, as well as the other soluble nitroprussides, is a most delicate test for alkaline sulphides, with which it strikes a violet color.

SODIUM PARACRESOTATE. $C_6H_3(OH)CH_3CO_2Na$. This salt is recommended as an internal antiseptic; it is prepared by heating creosol-sodium with carbonic acid, and occurs in colorless and odorless crystals of bitter taste, insoluble in cold water, soluble in warm water. In the *diarrhœa* of children it is given in doses of from five to forty-five grains (0·35–2·9 Gm.).

SODIUM SILICATE. *Sodii Silicas. Soluble Glass.* Na_2SiO_3, or frequently $Na_2Si_4O_9$. Sodium silicate is made by fusing one part of silica, fine sand, or powdered flint, and two parts of dried sodium carbonate, mixed in powder, in an earthenware crucible, and pouring out the fused mass on a stone slab to cool. This is pulverized, and treated with boiling water, to dissolve the soluble part. The solution is filtered and concentrated, so as to form crystals on cooling. These are then purified by dissolving them in water heated to 37·7° C. (100° F.), filtering the solution, and concentrating it so that it may recrystallize. The commercial *solution of sodium silicate* usually contains about 20 per cent. of silica and 10 per cent. of soda. (See *Liquor Sodii Silicatis*, p. 825.) It is employed in fixing fresco colors by the process of stereochromy, as a cement in the manufacture of artificial stone, and as an addition to soaps, constituting the so-called "silicate soaps." As long ago as 1872, Dumas, Rabuteau, Papillon, Picot, Champouillon, and other French writers asserted that sodium silicate was an antiseptic, valuable in the treatment of chronic *urethritis*, *vaginitis*, etc., and P. Coreman has shown that pathogenetic germs are killed in one hour by its solution. (*La Presse Méd.*, 1897.) R. Lõwenhaupt, however, asserts that when pure it is not antiseptic, any powers which it may seem to have being dependent upon the presence of free soda in it, and certainly as a practical remedy it has failed to come into use.

SODIUM SILICO-FLUORIDE. Na_2SiF_6. When gaseous SiF_4, generated by the action of sulphuric acid upon fluorspar in the presence of broken glass, is led into water, hydrogen silico-fluoride, H_2SiF_6, is formed. This acid, when neutralized by sodium hydrate or carbonate, will yield the sodium salt. It is difficultly soluble in water. It is asserted for the *silico-fluoride of sodium* that its solution, *salufer*, is practically non-toxic and powerfully antiseptic. The powder is a strong irritant or a mild caustic. The solution affects steel instruments. Mr. Bokenham, in experiments upon bacteria, found that in order to kill them it was necessary for the solution to be at least one to seven hundred and fifty parts; and that the drug has toxic properties, 0·05 Gm. of it causing prolonged nausea, great slowing of the pulse, and reduction of the arterial pressure.

SODIUM SULPHOMETHYLATE. $CH_3Na_2SO_4,H_2O$. According to Rabuteau, this salt in 240-grain (15-Gm.) doses produces catharsis without cramp. (*A. J. P.*, 1880, 220.)

SODIUM SULPHOSALICYLATE. *Sodium Salicylsulphonate.* $C_6H_3(OH)<^{COOH}_{SO_3Na}$. Salicyl sulphonic acid, made by acting on salicylic acid with sulphuric acid, is partly neutralized with sodium carbonate. It occurs as a white crystalline powder, soluble in twenty-five parts of water, insoluble in alcohol and ether. It is used as a substitute for sodium salicylate.

SODIUM SULPHOVINATE. *Sodium Ethylsulphate.* $C_2H_5NaSO_4,H_2O$. This salt occurs as a white granular powder or in hexagonal tabular crystals, according to the method of its preparation. Its taste is cooling and rather aromatic, nearly destitute of bitterness. It is very deliquescent, and is soluble in 0·7 part of water.

When sulphuric acid is added to alcohol the temperature rises at once, and a certain proportion of sulphovinic acid is formed, but, as water is at the same time developed, the reaction is soon arrested by the dilution of the mass. The first practical method of overcoming the difficulty was afforded by the process of Limousin. Nineteen and a half

ounces (avoirdupois) each of pure sulphuric acid, sp. gr. 1·715, and of concentrated alcohol, about 96°, are slowly introduced by means of two funnels (one for the alcohol and the other for the acid) into a third funnel arranged in a flask plunged into a freezing mixture or kept in a current of cold water, the flow of the two liquids into the flask being so regulated as to keep the alcohol in excess. The mixture is kept for four or five days at a temperature of from 20° C. (68° F.) to 25° C. (77° F.), then diluted with from nine to ten pints of distilled water, and carefully saturated with somewhat less than forty-eight ounces of pure barium carbonate in solution. When the point of saturation has been attained, the liquid is left to deposit the barium sulphate, and afterwards filtered. The solution of barium sulphovinate so obtained is saturated with between twenty-seven and twenty-nine ounces of pure sodium carbonate dissolved in four litres of distilled water. When no more precipitate is formed by the addition of the alkaline solution, and the liquid is neutral to test-paper, the transformation of the barium sulphovinate into sodium sulphovinate is complete. The liquor, decanted and filtered, is evaporated in a water-bath until it has the sp. gr. 1·33, and left to crystallize. The drained crystals are dried in a stove.

Recently, various other processes have been proposed. T. L. Phipson (*Chem. News*, 1874, 221; also *A. J. P.*, xlvii. 27) mixes small quantities of concentrated sulphuric acid and alcohol; keeps for from eight to ten hours at a temperature of 37·7° C. (100° F.); cools; adds the mixture drop by drop to about twenty times its volume of cold distilled water, cooling at times; adds chalk to this solution until effervescence ceases; filters, heats the filtrate with a little calcium carbonate for about half an hour; filters while warm, and evaporates at a heat not exceeding 37·7° C. (100° F.) till a permanent saline crust forms on the surface, and sets aside to crystallize. The calcium sulphovinate thus formed is in large brilliant plates, readily converted into a corresponding salt of sodium. M. Dubois modifies (*Journ. de Pharm.*, 1875, 44) the method of Limousin by saturating the first mixture, containing sulphovinic acid, with a concentrated solution of caustic soda in strong alcohol, keeping the mixture constantly cold, and adding the alkaline mixture by small portions. The filtered liquid is evaporated as in the method of Phipson, or, preferably, Dubois precipitates the mixture, diluted with strong alcohol, with sodium carbonate. Limousin's process, as thus modified, appears to be preferable to that of Mr. Chas. Rice, detailed in *A. J. P.*, 1873, 60. Sodium sulphovinate is said to be a mild although active cathartic. According to Dr. Rabuteau, five drachms (19·4 Gm.) of it dissolved in three glasses of water will generally produce in the adult four or five liquid stools without pain. The dose for children is from two to three drachms. The pleasantness of its taste and action would render it a favorite purgative were it not for its high price and the difficulty of preserving it, all of the sulphovinates having a great tendency on exposure to the air to break up into alcohol and a salt of sulphuric acid.

SODIUM TARTRATE. *Sodii Tartras.* $Na_2C_4H_4O_6,2H_2O$. This salt, in crystals, has been recommended by M. Delioux as an agreeable purgative, almost without taste, and acting with a power equal to that of the magnesium sulphate in the dose of ten drachms. The *soda powders*, so much used in the United States, form an extemporaneous sodium tartrate, somewhat aërated with carbonic acid. A *solution of sodium tartrate* has been used as a substitute for solution of magnesium citrate. It may be made by dissolving six drachms of tartaric acid in two fluidounces of water, and seven and a half drachms of sodium bicarbonate in seven fluidounces of water, mixing the solutions gradually and filtering; the filtrate should be poured into a strong twelve-fluidounce bottle and two fluidounces of lemon syrup added slowly, so that it will sink to the bottom of the bottle without mixing very much with the solution; eighty grains of tartaric acid are to be added without agitating the bottle, which is to be corked at once securely and set aside in a cool place. The bottle is to be shaken just before the contents are administered.

SODIUM TETRABORATE. *Antipyonin.* Sodium tetraborate is made by boiling borax and boric acid in water. It occurs as a fine, white powder, appearing to be greasy to the touch, freely soluble in water. This salt is non-poisonous, devoid of caustic action, and markedly antiseptic. It is probably therapeutically equivalent to borax, but has been especially recommended in a 2 to 50 per cent. solution, or blown in as a powder, by Jaenicke and by Kafemann in *acute* and *chronic otorrhœa*. Roland attributes extraordinary effects to its insufflation in *keratitis*, *conjunctivitis*, and other inflammatory eye conditions.

SOJA HISPIDA. Moench. (Now *Glycine Soja*, Sieb. and Zucc.) *Soja Bean.* (Nat. ord. Leguminosæ.) Meissel and Böcker (*A. J. P.*, 1885, 108) give the composition of soja bean as follows: water, 10 per cent.; soluble casein, 30; albumen, 0·5; insoluble casein, 7; fat, 18; cholesterin, etc., 2; dextrin, 10; starch, 5; cellulose, 5; ash, 5; traces of sugar and an amido compound. Stingl and Morawski (*Monatsschrift für Chemie*, April, 1886) have determined the presence in this bean of a ferment said to be one of the most powerful known in its action upon starch, two-thirds of which it converts into sugar and one-third into dextrin. The amount of starch present in soja bean is so little that bread made from the meal may be used in diabetes. (*A. J. P.*, 1896, 309.)

SOLANUM CAROLINENSE. L. (Nat. ord. Solanaceæ.) Horse nettle is a coarse perennial weed, growing in waste ground and sandy soil over almost the whole of the United States as far west as Iowa and south as Florida. It is abundantly furnished with stout yellowish prickles and with coarse four- to eight-rayed hairs. Calyx lobes acuminate; corolla violet; anthers elongated, yellowish, equal. The fruit is an orange-yellow berry. For study of microscopic structure, see *A. J. P.*, vol. lxix. It has been examined by G. A. Krauss (*A. J. P.*, 1890, 601, and 1891, 65 and 216) and Harry Kahn (*A. J. P.*, 1891, 126). Krauss found two active principles corresponding probably to *solanine*, $C_{42}H_{75}NO_{15}$, and *solanidine*, $C_{28}H_{41}NO_2$, together with a characteristic organic acid to which he gives the name *solanic acid*. Prof. J. U. Lloyd believes that the alkaloid in this plant is not identical with solanine, and proposes to call it *solnine*. (*A. J. P.*, 1894, 61, and 1897, 76, 89, 108.)

Dr. E. Q. Thornton *Therap. Gaz.*, xii. 1896) finds that in frogs solanum produces stupor with tetanic spasms, not prevented by section of the cord.

In 1889 *Solanum carolinense* was recommended by Dr. J. L. Napier in the treatment of epilepsy,

and has since been used to a considerable extent in that disease. It has been largely employed in Dr. H. C. Wood's Clinic in the University of Pennsylvania and in his private practice, and the conclusion has been reached that whilst given by itself its powers in epilepsy are very limited, when used as an adjuvant to the bromides it lessens the size of the doses necessary to keep the convulsions in check. Not less than a fluidrachm of the fluid extract should be given three times a day. No unpleasant effects have ever been produced by it.

W. S. Amos has found an alkaloid in the *S. rostratum*, Dunal, or *bull nettle*, of Western America. (*Notes on N. R.*, iv., 1891.) Mr. D. Freire has obtained from the fruit of the *S. grandiflorum*, or *wolf-fruit*, of Brazil an energetic toxic alkaloid, *grandiflorine*. (*Compt-Rend.*, cv.)

SOLIDAGO. *Golden-rod. Verge d'Or*, Fr. *Goldruthe*, G. There are very numerous species of this composite genus in the United States. Of these *S. odora*, Ait., was formerly official. *S. virgaurea*, L., which is common to the United States and Europe, was formerly directed by the Dublin College. It is aromatic, astringent, in hot infusion diaphoretic, and is asserted to be diuretic. (*Rev. Gén. de Clin. et de Thérap.*, 1889.) For a study of the flowers of *S. bicolor* by Mr. Adam Conrath, see *A. J. P.*, 1873, 253. For an analysis of *S. rugosa*, see *A. J. P.*, 1893, 122.

SOLPHINOL. A white, odorless, crystalline powder, consisting chiefly of boric acid, borax, and alkaline sulphites. It is soluble in ten parts of water and twenty parts of glycerin. It is used as a surgical antiseptic.

SOLUBLE MERCURY OF HAHNEMANN. $NH_2(Hg_2)NO_3$. This is prepared by adding, drop by drop, a dilute solution of ammonia to an equally dilute solution of mercurous nitrate, until the precipitate begins to be paler than at first. It is a black powder. When it has a gray color, the fact shows that too much ammonia has been employed in its precipitation. In this case $NH_2(Hg_2)NO_3$ yields $NH_2(Hg)NO_2 + Hg$. This preparation was included in the old French Codex. It has been used in *syphilitic* diseases.

SOLUTOL. An alkaline solution of sodium cresol in an excess of cresol. It is used for disinfecting purposes.

SOLVEOL. A solution of cresol in sodium-cresotate. It is less caustic than solutol, is nearly odorless, of a neutral reaction, and miscible with water. It is used as a surgical antiseptic, for dressings, and in spray apparatus.

SOMNAL. $C_7H_{12}Cl_3O_3N$. This is said to be a solution of chloral hydrate and urethane in alcohol. Dr. Tcheremshansky, in a physiological study, has found that it acts upon the nerve-centres and upon the circulation almost exactly as does chloral, it being, however, a little less depressing to the heart. Myers (*N. Y. Med. Record*, 1892) has reached similar conclusions.

Somnal, therefore, appears to be physiologically equivalent to a mixture of chloral and urethane, and it does not seem to be clear that it possesses any advantage over the older remedies. It may be given in doses of from one-half to one fluidrachm (1·9–3·7 C.c.), although much larger quantities have been used by some clinicians.

SONCHUS OLERACEUS. L. *Sow Thistle.* (Nat. ord. Compositæ.) The brownish gum left after the evaporation of the juice of this plant is said to be a powerful hydragogue cathartic, in doses of from two to four grains (0·130–0·259 Gm.). Combined with aromatics or belladonna, it may be used instead of elaterium in *dropsy*. (*Med. Bull.*, July, 1888.)

SONORA GUM. Under the name of *Sonora gum* is sold, it is said for the use of brewers, a gum-resin with a peculiar acidulous taste which is affirmed to be an exudation from the branches of *Larrea mexicana*, Moric. (nat. ord. Zygophyllaceæ), and to be the same substance as *Arizona shellac*. (*A. J. P.*, 1880, 400.) For details, see *P. J. Tr.*, vol. xvi. 128.

SOOT. *Fuligo Ligni.* This well-known substance has a peculiar smell, and a bitter, empyreumatic, and disagreeable taste. Its composition varies according to the source and conditions of its formation. When obtained by the combustion of resinous materials it may contain oily distillation products soluble in ether; when obtained by the combustion of wood it may contain pyroligneous (acetic) acid and products peculiar to wood-tar, such as creosote, guaiacol, and phenols. Of course mineral substances from the ash of the wood may also be present.

Soot was formerly official with the Edinburgh College, and the Scotch physicians prescribed it as a tonic and antispasmodic. It has also been employed as an external remedy in skin diseases. (See *Revue Méd.*, June, 1834; *Bull. Gén. de Thérap.*, Mars, 1834; also 14th ed. *U. S. D.*) A few shovelfuls of it, thrown into privies or drains, effectually destroy their foul exhalations.

SOPHORA SPECIOSA. Benth. (Now *S. secundiflora*, Lag. ex D. C.) From the poisonous seeds of this leguminous Texan tree H. C. Wood obtained a volatile liquid alkaloid (*sophorine*) whose chloride is crystalline (see *A. J. P.*, 1878), which, according to P. C. Plugge, is identical with cytisine. This same alkaloid probably exists in many species of the genus, as Parsons found a liquid alkaloid in *S. sericea*, which grows in Colorado and Mexico (*Rep. Commissioner of Agricult.*, 1879, and *N. R.*, 1881, 67. See also reports of an investigation by M. Kalteyer and W. E. Neil, *A. J. P.*, 1866, 465), and Dr. Greshoff (*P. J. Tr.*, xxii.) one in *S. tomentosa*, L. Plugge, however (*Arch. d. Pharm.*, 1895) affirms that *matrine*, the alkaloid discovered by Nagai in *S. angustifolia*, is distinct from cytisine.

SORBUS AUCUPARIA. L. (*Pyrus aucuparia*, Ehrh.) *Mountain Ash. Sorbes*, Fr. *Eberesche*, *Vogelbeere*, G. (Nat. ord. Rosaceæ.) A small European tree, whose fruit contains a peculiar kind of sugar called *sorbin*, $C_6H_{12}O_6$, susceptible of the vinous fermentation; an alcoholic drink has been prepared from it. It seems to have been used for preparing malic acid; and Dr. Hofmann has discovered in it two new acids, which he designates as *sorbic* and *parasorbic acids*, $C_6H_8O_2$. M. J. Boussingault has found in it a crystalline saccharine principle, *sorbite*, isomeric with mannite, melting, when anhydrous, at from 110° to 111° C. (230°–231·8° F.), when hydrated, at 102° C. (215·6° F.). Its formula is $C_6H_{14}O_6$. It does not undergo the vinous fermentation. (*P. J. Tr.*, 1872, 28.) It has been used in *scurvy*, and, in infusion, as a remedy in *hemorrhoids* and *strangury*. All parts of the tree are astringent, and may be employed in tanning and dyeing black. *S. americana*, Marsh. (*Pyrus americana*, D. C.), or American Mountain Ash, probably has similar virtues to the European species. Edwin Johanson found the fruit to yield

from 4·92 to 6·6 per cent. of malic acid. (*Pharm. Zeitschr. f. Russl.*, i., 1882.)

SORGHUM. *Sorghum*, or *Chinese Sugar-cane*, is yielded, according to Hoekel, by a number of varieties of *Andropogon arundinaceus*, Scop. Some of the varieties indigenous in India, China, and other parts of the East have within a few years been introduced into Europe and the United States. It has come largely into cultivation in the United States, owing in great part to the efforts of the Department of Agriculture, whose numerous publications upon the subject may be consulted by any one desirous of information.

SOZAL. $(C_6H_4(OH)SO_3)_3Al$. *Aluminum Paraphenolsulphonate.* This is obtained by dissolving aluminum hydrate in paraphenolsulphonic acid, or by double decomposition of aluminum sulphate and barium paraphenolsulphonate. It occurs in crystalline grains having a weak phenol odor, but strongly astringent taste; easily soluble in water, glycerin, and alcohol, forming permanent solutions. It has been used as an antiseptic in place of iodoform. (*Pharm. Ztg.*, 1892.)

SOZIODOL. *Soziodolic Acid. Diiodparaphenolsulphonic Acid.* $C_6H_2I_2(SO_3H)OH$. This is a white glittering powder, odorless, of slightly acid taste, slightly soluble in cold water, more easily in hot water. It is decomposed on heating to 200° C., giving off violet vapors. It contains 52·8 per cent. of iodine. It can be recognized by heating, or by adding sulphuric acid to it in hot solution, when iodine separates. Ferric chloride imparts a dark violet color to the aqueous solution; silver nitrate throws down a white precipitate of silver soziodol completely soluble in dilute nitric or sulphuric acid. For an outline of the process of manufacture, see *Squibb's Ephemeris*, Feb. 1893. Soziodol is used as a local remedy, resembling somewhat iodoform in its range of usefulness. According to Langaard, 2 per cent. is sufficient to kill bacteria of pus; for wounds, a 10 per cent. mixture with powdered talc is advocated. Lassar praises it in *eczema*, *herpes tonsurans*, *impetigo*, etc.; it has also been much used in *otitis* and *rhinitis*. Langaard has found that fifteen-grain doses have no appreciable effect upon rabbits, and Bufalini gave twenty-two grains a day in *phthisis* without unpleasant effect. The following salts have been used.

Sodium soziodol, readily soluble; used in all cases where aqueous solutions are employed. *Potassium soziodol*, sparingly soluble; a desiccant indicated in *eczema*. It is usually employed with talc in the proportion of 1–5 or 1–6. *Zinc soziodol*, a local irritant in solutions of from 1–20 to 1–50; a caustic in a solution of 1–5. *Mercury soziodol*, a caustic, even in a solution of 1–10. Miller affirms that its solution of 2½ in 100 kills the acarus of *scabies* in twenty-four minutes.

SOZOLIC ACID. *Acidum Sozolicum. Orthophenolsulphonic Acid.* $C_6H_4(HSO_3)OH$. Ortho- and paraphenolsulphonic acids are both formed when phenol is dissolved in concentrated sulphuric acid; at medium temperatures the former is far more abundant, but it readily passes into the para compound on the application of heat. Sozolic acid has a very faint odor of carbolic acid, and is asserted to be antiseptic but not poisonous nor irritant, and therefore to be especially valuable in abdominal and ophthalmological surgery. It is readily soluble in water, alcohol, and glycerin, and is used so diluted as to contain from 3 to 10 per cent. of the active principle. The orthophenolsulphonic acid in 33⅓ per cent. solution is what has received the trade name of *aseptol*. The ortho acid changes on heating into the isomeric paraphenolsulphonic acid, and this change takes place even in the aqueous solution of the former, a fact which should be remembered in the preparation of aseptol solutions. In spite of the allegations to the contrary, it is probably poisonous.

Prof. E. Riegler (*Wien. Med. Blätt.*, xviii. 1895) proposes aseptol as a test for *albumin* in urine. 1 in 20,000 causes coagulation. The precipitate with albumin does not disappear with heat. The solutions of albuminose and peptones are also precipitated, but the precipitates of these disappear with heat. The solution of aseptol undergoes decomposition with light.

Schiff and Beilstein asserted that phenolsulphonic acid acts like tannic and gallic acids, precipitating albumen and alkaloids, and being capable of replacing gallic acid in the making of leather and in pharmacy. There is, however, no sufficient reason for believing that the substance can be used in medicine in the place of the vegetable acids named. It has also been asserted that phenolsulphonic acid is a more powerful antiseptic than phenol, having the great advantage of being nearly odorless, non-irritating, non-poisonous, and miscible with water in all proportions. That it is nearly free from poisonous properties is not probable, and in a careful series of comparative experiments, Mr. F. A. Tucker (*Notes on New Remedies*, 1892) found that it had not more than one-third the antiseptic power of carbolic acid.

SPARTIUM JUNCEUM. L. *Spanish Broom.* (Nat. ord. Leguminosæ.) A small shrub, indigenous in the south of Europe, and cultivated in our gardens as an ornamental plant. The flowers are large, yellow, and of an agreeable odor. The seeds are in moderate doses diuretic and tonic, in large doses emetic and cathartic, and have been used advantageously in *dropsy*. Dose, from ten to fifteen grains (0·6–0·9 Gm.) three times a day in tincture.

SPHACELOTOXINE. *Spasmotin. Spasmotoxin.* $C_{20}H_{21}O_9$. A crystalline yellow powder isolated by Jacoby from ergot. (*Amer. Therap.*, 1894, 295.) It is insoluble in water, in diluted acids, and in benzin; soluble in ether, alcohol, and benzol. It forms salts with alkalies, the soda salt being recommended for hypodermic injections. It is asserted that sphacelotoxine is the active constituent of ergot. The dose is from one-thirtieth to one-twelfth of a grain (0·002–0·005 Gm.), but doses up to one grain have been given without danger.

SPHÆRANTHUS INDICUS. L. (Nat. ord. Compositæ.) An Indian plant, which is used as a general tonic, deobstruent, alterative, and aphrodisiac, under the names of *Mundi*, *Gorakhmundi*, *Murmuria*, and *Kottakkarandai*. Prof. Dymock has found in it a deep cherry-colored essential oil.

SPILANTHES OLERACEA. L. (Now *S. Acmella*, Murr.) *Para Cress. Cresson de Para*, Fr. *Parakresse*, G. (Nat. ord. Compositæ.) A plant of India, used as a masticatory for toothache; when chewed it produces a copious salivation. (*A. J. P.*, xliv. 323.)

SPIRÆA. Many if not all of the species of this genus contain a colorless volatile oil, very

similar to the oil of gaultheria, and, like it, largely composed of salicylic aldehyde. The species which have been submitted to actual analysis are the *Spiræa ulmaria*, L.,—*Queen of the Meadow*, or *Meadow-sweet*,—a European plant which has been introduced into this country; also the European species *S. lobata*, Jacq., and the species *S. filipendula*, L., which grows in Southern Europe and Northern Africa. A yellow, crystalline powder of a bitter taste, insoluble in water, slightly so in alcohol, readily soluble in ether, and having an acid reaction. *Spiræic acid* (*Journ. f. Prakt. Chemie*, xix.) was separated from the flowers of *S. ulmaria* by Löwig and Weidmann, and has been found by Rochebrune in the flowers of *S. filipendula*, L.

The roots of probably most of the species contain tannic acid, gallic acid, and when fresh some of the volatile oils. (*A. J. P.*, 1887.) The root of *Spiræa tomentosa*, L., was formerly recognized in the U. S. Pharmacopœia. It (*Hardhack*, *Steeplebush*, or *Whitecap*) is an indigenous shrub, two or three feet high, with numerous simple, erect, round, downy, and purplish stems, furnished with alternate leaves, closely set upon very short footstalks. The leaves are ovate-lanceolate, unequally serrate, somewhat pointed at both ends, dark green on their upper surface, whitish and tomentose beneath. The flowers are a beautiful red or purple, and disposed in terminal, compound, crowded spikes or racemes.

The flowers of the Spiræa possess to a very feeble extent the medical virtues of salicylic acid, and have been used as diuretic and tonic in the form of decoction. The roots are astringent, and have been used in the treatment of *diarrhœa* in doses of from five to twenty grains (0·3–1·3 Gm.) of the aqueous extract repeated *pro re nata*.

SPIRITUS ODORATUS. *U. S.* 1880. *Perfumed Spirit. Cologne. Eau de Cologne*, Fr. *Kölnerwasser*, G. "Oil of Bergamot, *sixteen parts* [or two fluidounces]; Oil of Lemon, *eight parts* [or one fluidounce]; Oil of Rosemary, *eight parts* [or one fluidounce]; Oil of Lavender Flowers, *four parts* [or half a fluidounce]; Oil of Orange Flowers, *four parts* [or half a fluidounce]; Acetic Ether, *two parts* [or two fluidrachms]; Water, *one hundred and fifty-eight parts* [or eighteen fluidounces]; Alcohol, *eight hundred parts* [or six and a half pints], To make *one thousand parts* [or about eight pints]. Dissolve the Oils and the Acetic Ether in the Alcohol, and add the Water. Set the mixture aside, in a well-closed bottle, for eight days, then filter through paper, in a well-covered funnel."

Cologne water was introduced into the Pharmacopœia of 1880, but was dropped at the last revision. In our opinion a more fragrant spirit, and one more closely resembling the original, would be made if the quantity of oil of orange flowers or *neroli* were doubled. Cologne water is often useful in the sick-room as a refreshing perfume.

SPLENIC EXTRACT. Led by the spontaneous recovery of a severe exophthalmic goitre during an attack of abscess of the spleen, and the well-known relations between diseases of the spleen and myxœdema, H. C. Wood tried the splenic extract in various cases of *exophthalmic goitre* with sufficient results to make further clinical investigation incumbent upon the profession. The experiments of Oliver and Schäfer show that the intravenous injection of the splenic extract produces in the dog a primary fall and a secondary rise of the arterial pressure; beyond this we have no definite knowledge of the physiological action of the extract. It has been used by A. C. Clark with apparent beneficial results in a number of cases of *insanity* connected with nervous exhaustion. He states that it increases the activity of the skin, usually increases the appetite, and has no effect upon the bowels, the urine, or the blood. In the practice of H. C. Wood a disadvantage has been the tendency of the extract to produce nausea, or, if used hypodermically in the form of the glycerin extract, to cause abscesses. In teaspoonful doses the glycerin extract (40 per cent.) has in some cases provoked violent gastric distress. Dose of the glycerin extract, from ten to twenty minims (0·6–1·2 C.c.) three times a day; dose of the solid extract, from three to five grains (0·2–0·33 Gm.) in capsules.

SPONGE. *Spongia. Spongia officinalis. Eponge*, Fr. *Schwamm, Badeschwamm*, G. This sponge is "a flexile, fixed, torpid, polymorphous animal, composed either of reticulate fibres or masses of small spires interwoven together, and clothed with a gelatinous flesh, full of small mouths on its surface, by which it absorbs and ejects water." Various genera are described, but the sponges used in commerce are said all to belong to the genus *Spongia*. Sponges inhabit the bottom of the sea, where they are fixed to rocks or other solid bodies, and are most abundant within the tropics. They are collected chiefly in the Mediterranean and Red Seas, and in those of the East and West Indies. When collected they are enveloped in a gelatinous coating, which forms part of the animal. For details of fishery and preparation, see *P. J. Tr.*, xx. Large quantities of the coarser kinds are imported from the Bahamas, but the finest and most esteemed are brought from the Mediterranean, especially from the coast of Syria. Recently the cultivation of sponges has been undertaken on an extensive scale. Small fragments are cut under water from the live sponge, and fixed upon a sandy bottom by means of skewers. In three years they will have grown sufficiently to be marketable.

Sponge, as found in commerce, is in yellowish-brown masses of various shapes and sizes, light, porous, elastic, and composed of fine, flexible, tenacious fibres, interwoven in the form of cells and meshes. It usually contains numerous minute fragments of coral or stone, or small shells, from which it must be freed before it can be used for ordinary purposes. Sponge is prepared by macerating it for several days in cold water, beating it in order to break up the concretions which it contains, and dissolving what cannot thus be separated of the calcareous matter by hydrochloric acid diluted with thirty parts of water. By this process it is rendered perfectly soft, and fit for surgical use. It may be bleached by steeping it in water impregnated with sulphurous acid, or by exposure in a moist state to the action of chlorine. It is stated that sponges which have been soaked in pus and infectious matters will recover their primitive condition, even to the marine odor, by soaking in a 4 per cent. solution of potassium permanganate, then in a 25 per cent. solution of sulphurous acid, and finally thorough washing in an abundance of water. (*A. J. P.*, xliv. 355.) (See *Spongia Decolorata*, National Formulary, page 1530.) When intended for surgical purposes, the softest, finest, and most elastic sponges should be selected; for forming *burnt sponge* the coarser will answer equally well.

According to Mr. Hatchett, the chemical constituents of sponge are gelatin, coagulated albumen, common salt, and calcium carbonate. Magnesia, silica, iron, sulphur, and phosphorus have been detected in it, as also iodine and bromine, combined with sodium and potassium. From the experiments of Mr. Croockewit, it would appear that sponge is closely analogous to, if not identical with, the *fibroïn* and *sericin* of silk, differing from it only in containing iodine, sulphur, and phosphorus. (*Annal. der Chem. und Pharm.*, xlviii. 43.) Schlossberger, however, has shown that it is distinct in its very slight solubility in ammoniacal solution of copper hydrate and in its yielding leucine and glycocoll when treated with dilute sulphuric acid, while sericin yields under similar treatment tyrosine and serin. He names the principle *spongin*.

Sponges are used for mechanical purposes only. *Sponge tent* is employed for dilating sinuses. This is prepared by dipping sponge into melted wax, compressing it between two flat surfaces till the wax hardens, and then cutting it into pieces of a proper form and size. By the heat of the body the wax becomes soft, and the sponge, expanding by the imbibition of moisture, gradually dilates the wound or sinus in which it may be placed. When a conical sponge tent of uniform calibre is required, as for dilating the uterine cavity, a better plan is to cut the sponge into a conical shape whilst fresh and compress when moist, by winding it carefully with a fine tightly drawn cord, removing the cord when perfectly dry, and dipping the tent into melted wax, so as to get a thick coating. For other modes of preparing sponge tent, as well as of saturating the sponge at the same time with substances calculated to make a remedial impression, as carbolic acid, alum, lead acetate, etc., see *A. J. P.*, 1868, 410; 1869, 446.

SPONGIA USTA, *Burnt Sponge*, was formerly official (*Spongia Usta, U. S.* 1850), but is no longer used in medicine. For method of preparation, analysis, and therapeutic properties, see 16th ed. *U. S. D.*

STATICE CAROLINIANA. Walt. (*Limonium Carolinianum.* (Walt.) Britt.) *Marsh Rosemary. Ink-root. Sea-lavender. Romarin des Marais, Lavande triste*, Fr. *Strandnelke*, G. (Nat. ord. Plumbaginaceæ.) It is an indigenous maritime plant with a perennial root, sending up annually tufts of leaves, which are obovate or cuneiform, entire, obtuse, mucronate, smooth, and on long footstalks.

Marsh rosemary grows in the salt marshes along the sea-coast from New England to Florida, and flowers in August and September. The root, which was formerly in the Secondary List of the U. S. Pharmacopœia, is large, spindle-shaped or branched, fleshy, compact, rough, and of a purplish-brown color. It is bitter and extremely astringent, but odorless. It contains tannic acid (12·4 per cent.), volatile oil, resin, and other substances. (*A. J. P.*, xiv. 116.) Statice is powerfully astringent, and in some parts of the United States, particularly in New England, is much employed, especially as a local application, in decoction, to aphthous and ulcerative affections of the mouth and fauces.

In Brazil and Buenos Ayres the roots of *S. brasiliensis*, Boiss., and *S. antarctica* are employed under the name of *Buaycura* or *Guaycura*. (*P. J. Tr.*, 1878, ix. 466.) For a description of the physical and chemical characteristics of the root, see *P. J. Tr.*, vol. xv. 86. In Russia and Spain the very large roots of *S. latifolia*, Sm., are used for tanning, and in Morocco the roots of *S. mucronata*, L., are employed, under the name of *safrifa*, as a nervine.

STERCULIA ACUMINATA. Beauv. (Now *Cola acuminata*, R. Br., also Schott and Endl.) *Semen* (*Nuces*) *Colæ. Noix de Cola, Noix de Gourou, Café du Soudan*, Fr. *Kolanuss*, G. This large African tree is extensively cultivated in various portions of the tropical world for its nuts, which, under the Guinea name of *kola nuts*, or the Soudan name of *guru nuts*, are extensively employed as a caffeinic stimulant in Africa and other portions of the world. Six hundred tons of them are said to be sent yearly to Brazil for the use of the negroes, who, it is affirmed, also employ the seeds of *S. chica*, A. St.-Hil., and *S. lasiantha*, Mart. (now *S. striata*, A. St.-Hil.). The kola nut itself is irregular in form, reddish gray in color, from three-quarters of an inch to an inch and a quarter in length, flattened and rounded upon one surface, irregularly scooped out or infolded upon the other surface, the nut being apparently a cotyledon, marked above with another cotyledon which it has embraced. For a detailed description of the nuts and their commercial varieties, see pamphlet by Dr. Bernhard Schuchardt. Dr. Daniell (*P. J. Tr.*, 1865) was the first to show that kola nuts contained caffeine. Subsequently an elaborate analysis yielded to Dr. Attfield 2½ per cent. of caffeine from the nut. Schuchardt summarizes the results of his chemical analyses as follows: 1, Martinique nuts contained 1·06 per cent. caffeine; 2, Ceylon, 1·39 per cent.; 3, Gaboon, 1·47 per cent.; 4, Tropical West Africa coast, Sierra Leone, 1·69 per cent.; 5, Tropical West Africa, interior, 1·61 per cent. The chemical studies of Parke, Davis & Co show that as found in American commerce these nuts contain from 0·72 to 2·02 per cent. of caffeine. Heckel and Schlagdenhauffen (*A. J. P.*, 1884) give theobromine 0·023 per cent., caffeine 2·35 per cent., tannin 1·62 per cent., as the result of their analyses. The researches of Knebel (*A. J. P.*, 1892, 190), confirmed by Hilger (*Ibid.*, 568), show that fresh kola nuts probably contain no caffeine, but a glucoside, *kolanin*, which yields by its decomposition caffeine, glucose, and *kola-red* ($C_{14}H_{12}(OH)_5$). The glucoside is decomposed by a ferment present in the nuts, and so readily yields the caffeine as a decomposition product. Schweitzer (1895) confirmed the results of Knebel and Hilger, and proposed for kolanin the formula $C_{40}H_{58}N_4O_{21}$. Knox and Prescott (*Proc. A. P. A.*, 1896, 136), after an investigation, assert that the kola ferment does not assist in the liberation of caffeine, but attribute the presence of caffeine to the action of heat and moisture; they also give the name of *kolatannin* or *kolatannic acid* to the tannin of kola nuts, and propose a method of assay. (*Proc. A. P. A.*, 1897, 131.) For Carle's method of assay, see *P. J. Tr.*, 1896, 289.

It has been asserted for kola nuts that they increase the power of enduring fatigue without food, and a dry powder or cake of kola nuts, deprived of their oil, is said to be used by the European Alpine clubs. Physiological studies have been made by Loginoff (*St. Petersburg Inaug. Dis.*, 1891), Davydoff (*St. Petersburg Inaug. Dis.*, 1891) and Kotlar (*Vrach*, 1891), which on the whole agree in showing the similarity of the action of the drug with that of others of its class. The question

whether the action of kola is simply that of caffeine has been much debated, especially owing to the strenuous efforts of a drug firm to introduce kola as a popular stimulant of peculiar power. Several French observers, especially Marie, have found that kola-red is a powerful muscle stimulant, even exceeding caffeine. The very elaborate studies, however, of Prof. A. Mosso, of Turin (*Arch. Ital. Biolog.*, xix.), seem to us decisively to establish the correctnesss of his conclusion,—namely, that kola-red is, at least so far as the muscles are concerned, an entirely inert substance, and that the action which kola undoubtedly has upon the muscular contraction is due to the caffeine which it contains. Kola is evidently about equivalent to guarana, tea, coffee, etc., and may be substituted for them. In dose of one hundred and fifty grains (9·7 Gm.) a day, A. Hudson (*Ther. Gaz.*, ii.) has found the nuts to act decisively in cardiac weakness.

The so-called *male kola* is essentially distinct from kola, being the product of a small tree, *Garcinia kola*, and containing no caffeine. The seed is oblong, about one and a half to three inches long and from three-quarters to one inch broad; it is trigonal in section, with a readily removable thin testa of a reddish-yellow to dark brown color, covered by markings which resemble those on the seed-coat of the nutmeg. In the section the microscope reveals a number of resinous masses surrounded by cells rich in starch.

The seeds of the *Lucuma mammosa*, sometimes mixed with kola nuts, are recognized at once by their strong odor of prussic acid. Heckel and Schlagdenhauffen have observed the seeds of *Heritiera littoralis* mixed with kola nuts. These *false kola nuts* contain no caffeine, and are nearly orbicular and flattened in shape, one of the fleshy, white cotyledons being only half the size of the other. (*A. J. P.*, 1887, 446.)

STERCULIA GUM. A number of trees belonging to the genus *Sterculia* in India, Africa, and Australia yield gums in considerable quantity, most of which resemble in their appearance tragacanth, and some of which have remarkable adhesive properties. These gums have not, however, become important articles of commerce, and for an account of them the reader is referred to a paper by J. H. Maiden. (*P. J. Tr.*, Nov. 1889.

STERESOL. An antiseptic varnish made by dissolving purified gum lac 270 parts, benzoin 10 parts, balsam Tolu 10 parts, carbolic acid crystals 100 parts, oil of cinnamon 6 parts, saccharin 6 parts, in sufficient alcohol to make 1000 parts. It permits of asepsis of mucous surfaces, and is adapted for use where it is impossible to apply bandages.

STERISOL. *Steriosol.* According to Aufrecht, this liquid contains formaldehyde, sodium chloride, potassium phosphate, sugar of milk, and water. It is used as an antiseptic.

STILLINGIA SEBIFERA. Michx. (Now *Sapium sebiferum.* Roxb.) *Tallow-tree. Tankawang Fat.* This is a species of the family Euphorbiaceæ, cultivated in the Chinese provinces of Kiang-se, Kiang-sou, and Chih-kiang for the sake of the fatty matters extracted from the nuts by methods detailed in *A. J. P.*, 1872, 264. (See also *P. J. Tr.*, June, 1872.) The "tallow" occurs in hard, brittle, opaque, white, tasteless, and odorless masses of about eighty pounds' weight. It is said to be nearly pure stearin. The oil is largely used for lighting purposes. The remnants of the nut are employed as fuel and as manure. (See also *P. J. Tr.*, 1883, 401, and *Ibid.*, 1887, 901.)

STIPA. According to Gillespie (*British Med. Journal*, Oct. 1898), a number of species of this genus of grasses are actively poisonous, and have caused death in horses and other domestic animals. Of such character especially are the *Stipa viridula*, Trin., the *Stipa inebrians*, Hance, and the *Stipa sibirica*, Lam., of the Russian steppes. A few experiments made with *Stipa viridula*, Trin., indicated that it acts powerfully upon the brain and spinal cord.

STRYCHNINÆ ARSENAS. *Strychnine Arsenate.* Dr. J. Russell praises this salt highly as a prompt means of getting the conjoint effects of its constituents; he employs its solution (1 to 250) hypodermically, and states the first dose as one-sixty-fourth of a grain, increased to one-sixteenth (0·001–0·004 Gm.). (*Wien. Med. Blätter*, Sept. 1886.)

STRYCHNOS POTATORUM. L. *Chilbinj. Clearing Nuts. Indian Gum Nuts.* (Nat. ord. Loganiaceæ.) The nuts of this species of Strychnos are very largely used in some parts of India for clearing muddy water, and are stated to have found their way into American commerce. (*A. J. P.*, 1871.) The fruit is also employed by the native practitioners of Hindostan, under the name of *nirmali*, as an emetic and in *dysentery.* They do not contain strychnine. In clearing water, one of the dried nuts is rubbed hard for a short time around the inside of the earthen water-pot; on settling, the water is left pure and tasteless. The seeds contain a large quantity of an albuminous principle, upon which their virtues probably depend. The tree, which grows to a very large size, produces a shining, black, one-seeded berry (that of the nux vomica being many-seeded). The seeds are described (*P. J. Tr.*, 1871, 44) as broadly lenticular, about half an inch in diameter and a quarter of an inch in thickness, of a dirty whitish-gray color, and covered with a thick coating of delicate appressed hairs. These are so small that the seed to the naked eye looks mealy. Under the microscope the hairs are seen to be agglutinated in bundles of from three to six, and to consist each of a single pointed cylindrical cell.

STYLOPHORUM DIPHYLLUM. Nuttall. (Nat. ord. Papaveraceæ.) According to Prof. E. Schmidt, the root of this American plant contains *chelidonine*, with a second alkaloid closely related to, if not identical with, *chelerythrine.* (*A. J. P.*, 1888.)

STYLOSANTHES ELATIOR. Sw. (Nat. ord. Leguminosæ.) It is asserted that this American plant has the power of relieving abdominal uterine pains during the latter months of gestation, and is also a uterine tonic during parturition. Dose of the fluid extract, from ten to twenty minims (0·6–1·2 C.c.) three times a day prior to confinement.

STYPTICIN. (See *Cotarnine Hydrochlorate*, p. 1627.)

SUBLIMO-PHENOL. *Phenolated Mercuric Chloride. Chloro-phenolate of Mercury.* Colorless crystals produced by precipitation from solutions of mercuric chloride and potassium phenolate, which are easily soluble in fused phenol or boiling aqueous or alcoholic solutions of phenol. It is used in antiseptic surgery.

SUCCINIC ACID. *Acidum Succinicum. Sal Succini Volatile. Acide succinique*, Fr. *Bernsteinsäure*, G. $C_4H_6O_4$. This acid is obtained by dis-

tilling amber. (See *Succinum.*) The product is an aqueous solution of impure succinic acid, associated with empyreumatic oil. (See *Oleum Succini.*) By filtering the liquor the soluiton of the impure acid passes through, while the oil is absorbed by the paper. The acid may be purified by boiling the solution with nitric acid, diluted with twice its bulk of water, and then evaporating to crystallize: should the crystals not be colorless, the treatment with nitric acid must be repeated until they are so. Succinic acid is made artificially by the action of nitric acid on the fatty acids, and may be produced in a great many ways from various substances. Thus, it is invariably formed in small amount in the alcoholic fermentation of sugar. M. Desaignes obtained it more advantageously from calcium malate subjected to fermentation excited by casein. The malate was converted into calcium succinate, which was then decomposed by sulphuric acid, so as to yield succinic acid. For the details of the process for obtaining succinic acid from calcium malate, see the paper of E. J. Kohl, in *A. J. P.*, vol. xxvii., July. Succinic acid, when pure, is in white, transparent crystals, having no odor and a somewhat acrid taste. It dissolves in five times its weight of cold and twice its weight of boiling water. It is less soluble in alcohol, but very sparingly in ether. Nitric acid is without action on it. It melts at 182° C. (359·6° F.), and boils without alteration at 235° C. (455° F.). It sublimes, however, at a much lower temperature. According to Wackenroder, it is sometimes adulterated with tartaric acid soaked in oil of amber. Succinic acid, though formerly official, is at present seldom used in medicine. It has been ascertained to be a product of vital action, having been detected by M. Heintz in the colorless liquid found in hydatid cysts of the liver. (See *Journ. de Pharm.*, Sept. 1850.) One of its salts, *ammonium succinate*, $C_4H_4(NH_4)_2O_4$, made by supersaturating succinic acid with ammonia, evaporating and crystallizing, has been used with great alleged success in *delirium tremens*. This salt is occasionally used as a precipitant of ferric oxide.

SUCCINUM. *Amber. Bernstein*, G. *Ambre* ou *Succin*, Fr. Amber is a fossil resin, occurring generally in small detached masses, in alluvial deposits, in different parts of the world. According to Goefert, there are about fifty species of extinct coniferous trees of which amber represents the resinous exudation. It is found chiefly in Prussia, either on the sea-shore, where it is thrown up by the Baltic, or underneath the surface, in the alluvial formations along the coast. It is said that the whole annual product of the Baltic coast of Prussia was in 1879 from 100,000 to 130,000 kilogrammes (100 to 130 tons). Large deposits occur in some lakes on the eastern coast of Courland, and an extensive bed of yellow amber was discovered in 1854, on sinking a well in the coal-mines near Prague. The largest mass of amber yet found weighed thirteen pounds. Amber also occurs in considerable quantities near Catania, in Sicily. It is usually associated with lignite, and sometimes encloses insects and parts of vegetables. In the United States, it was found at Cape Sable, Maryland, by Dr. Troost. In this locality it is associated with lignite and iron pyrites. It has also been discovered in New Jersey. The amber consumed in this country is brought from the ports of the Baltic. A mine of it is said to have been discovered near Rockwood in Australia.

It is a brittle solid, generally in small irregular masses, permanent in the air, having a homogeneous texture and vitreous fracture, and susceptible of a fine polish. It becomes negatively electric by friction. Its color is generally brownish yellow, either light or deep, but is occasionally reddish brown or even deep brown, and a Sicilian variety is green or bluish from staining with ferric phosphate. It has no taste, and is inodorous when cold, but exhales a peculiar, aromatic smell when heated. It is usually translucent, though occasionally transparent or opaque. Its sp. gr. is about 1·07. Water and alcohol scarcely act on it. When heated in the open air, it softens, melts at 548° F., swells, and at last inflames, leaving, after combustion, a small portion of ashes. Subjected to distillation in a retort furnished with a tubulated receiver, it yields, first, a yellow acid liquor, and afterwards a thin yellowish oil, with a yellow waxy substance, which is deposited in the neck of the retort and the upper part of the receiver. This waxy substance, exhausted by cold ether of the part soluble in that menstruum, is reduced to a yellow micaceous matter, identical with the *chrysen* of Laurent. A white crystalline substance, identical with the *idrialin* of Dumas, may be separated from the micaceous substance by boiling alcohol. Both chrysen and idrialin are hydrocarbons. (Pelletier and Walter, *Journ. de Pharm.*, v. 60.) As the distillation proceeds, a considerable quantity of combustible gas is given off, which must be allowed to escape. By continuing the heat, the oil gradually deepens in color, until, towards the end of the distillation, it becomes black and of the consistence of pitch. The oil obtained is called *oil of amber*, and the acid liquor is a solution of impure *succinic acid*. Repeatedly distilled from nitric acid, amber yields an acid liquor, from which, after it has been neutralized with caustic potassa, ether separates pure camphor. (Doepping, *Journ. de Pharm.*, vi. 168.) Borneol is also obtained by distilling to dryness powdered amber with an extremely concentrated solution of caustic potassa. (G. Reich, *Ibid.*, xiii. 33.)

According to Berzelius, amber consists of,—1, a volatile oil of an agreeable odor in small quantity; 2, a yellow resin, intimately united with a volatile oil, very soluble in alcohol, ether, and the alkalies, easily fusible, and resembling ordinary resins; 3, another resin, also combined with a volatile oil, soluble in ether and the alkalies, sparingly soluble in cold, but more soluble in boiling alcohol; 4, succinic acid; 5, a bituminous principle insoluble in alcohol, ether, and the alkalies, having some analogy to the lac resin of John, and constituting more than four-fifths of the amber. It also contains a strongly odorous, bright yellow substance, which hardens by time, but preserves in part its odor. The ultimate composition of amber is carbon 80·59, hydrogen 7·31, oxygen 6·73, ashes (silica, lime, and alumina) 3·27 = 97·90, representing, after the deduction of the ash, a formula $C_{10}H_{16}O$. A minute proportion of sulphur has also been found among its constituents. (*Journ. de Pharm.*, Mai, 1864, 404.)

Amber was held in high estimation by the ancients as a medicine, but at present is never so used. The *oil of amber* is an empyreumatic product which is prepared by destructive distillation of amber. The heat requisite for the complete decomposition of amber cannot be supported by a glass retort; and, in order that all the oil which it is capable of yielding may be collected, the distillation should be performed in a tubulated iron or earthenware

retort, which may be placed immediately upon the fire. The sand is added to prevent the amber from swelling too much. The oil may be separated from the acid liquor by means of the separating funnel. As first procured, it is a thick, very dark-colored liquid, of a peculiar strong empyreumatic odor. In this state it is occasionally employed as a liniment, but for internal use it should be rectified. It has the composition $C_{10}H_{16}$. It is almost impossible to procure pure oil of amber in commerce.

The U. S. Pharmacopœia of 1870, under the name of *Oleum Succini Rectificatum* or *Rectified Oil of Amber*, gave the following process. "Take of Oil of Amber *a pint;* Water *six pints.* Mix them in a glass retort, and distil until four pints of Water have passed with the Oil into the receiver; then separate the Oil from the Water, and keep it in a well-stopped bottle."

By successive distillations oil of amber becomes thinner and more limpid, till at length it is obtained colorless. The first portions which distil are less colored than those which follow, and may be separated for keeping, while the remainder is submitted to another distillation. For practical purposes, however, the oil is sufficiently pure when once redistilled. As usually found in commerce, the rectified oil is of a light yellowish-brown or amber color. As first distilled it has an amber color, the sp. gr. 0·903 at 15·6° C. (60° F.), and a boiling point from 170 5°–186·1° C. (339°–367° F.). (Ebert.) When quite pure it is said to be colorless, as fluid as alcohol, of the sp. gr. 0·758 at 23·8° C. (75° F.), and to boil at 85·5° C. (186° F.). It has a strong, peculiar, unpleasant odor, and a hot acrid taste. It imparts these properties in some degree to water, without being perceptibly dissolved. It is soluble in eight parts of alcohol of the sp. gr. 0·847, in five parts of the sp. gr. 0·825, and in all proportions in absolute alcohol, ether, chloroform, carbon disulphide, and the fixed oils. (Ebert.) On exposure to light and air, it slowly changes in color and consistence, becoming ultimately black and solid. It appears, when quite pure, to be a hydrocarbon of the terpene class. It is said to be sometimes adulterated with oil of turpentine, which may be detected by passing hydrochloric acid gas through the suspected oil. If pure it will remain wholly liquid; while oil of turpentine, if present, will give rise to the formation of solid artificial camphor. (*P. J. Tr.*, xiii. 292.) It was officially described as "a colorless or pale yellow, thin liquid, becoming darker and thicker by age and exposure to air, having an empyreumatic, balsamic odor, a warm, acrid taste, and a neutral or faintly acid reaction. Sp. gr. about 0·920. It is readily soluble in alcohol. When mixed with fuming nitric acid, it acquires a red color, and, after some time, is almost wholly converted into a brown, resinous mass of a peculiar musk-like odor." *U. S.*

Rectified oil of amber is stimulant and antispasmodic, and occasionally promotes the secretions, particularly that of urine. It has been employed with advantage in *amenorrhœa*, *hysteria*, and *whooping-cough*. The dose is from five to fifteen drops (0·3–0·9 C.c.), diffused in some aromatic water by means of sugar and gum arabic. Externally applied the oil is rubefacient, and is considerably used as a liniment in *chronic rheumatism*, and in certain spasmodic disorders, as *whooping-cough* and *infantile convulsions*. In the latter affection it should be rubbed along the spine.

SULPHALDEHYDE is made by the action of hydrogen sulphide upon acetaldehyde in aqueous solution. An oil is obtained which solidifies at low temperatures. According to Dr. Lusini (*Nouv. Rem.*, 1890), this substance acts on the lower animals as a powerful hypnotic.

SULPHAMINOL. $C_6H_4{<}^{S_2}_{NH}{>}C_6H_3{\cdot}OH$.

Thio-oxydiphenylamine. This compound is made by the action of sulphur upon the salt of metaoxydiphenylamine. It is a pale yellow powder free from odor and taste, readily soluble in alkalies, more difficultly so in alkaline carbonates, quite insoluble in water. When heated it turns brown, and melts at 155° C. It is asserted that this substance is harmless (see a paper by Prof. Kobert, *Journ. de Méd.*, Sept. 1890), and that when taken internally it is split up in the organism into oxydiphenylamine and sulphuric acid compounds. It has been used as a substitute for iodoform, having the advantage of being odorless. Internally, it has been given in doses of from four to five grains (0·26–0·32 Gm); externally, it may be used in powder or oily solutions. Various compound solutions of it have been employed as local applications to the mucous membranes of the nose and larynx, such as *Sulphaminol menthol*, *S. creosote*, *S. guaiacol*, *S. eucalyptol*.

SULPHITES, BISULPHITES, HYPOSULPHITES. These salts were introduced into medicine because of their extraordinary hostility, through their acid ingredient, to the lower forms, whether of vegetable or animal life. Microscopic plants and animals cannot exist in the presence of sulphurous or hyposulphurous acid; and, as their salts are easily decomposed, with the liberation of the acid, they are capable of exercising the same destructive influence. In parasitic diseases, such as *scabies*, *porrigo*, *prurigo senilis*, different forms of *ringworm*, *pityriasis versicolor*, the *sore mouth* or *thrush of infants*, etc., the local use of these remedies is often very efficient. In cases of *fermentative dyspepsia* the sulphites may be of value in checking the changes of the food. At one time it was supposed that they would be of value as germicides in *zymotic disease*, but theory indicates that unless given in poisonous doses they could have no influence upon disease germs in the system, and clinical experience has abundantly shown that they are valueless in zymosis.

Of the *sulphites*, those which have been employed are *sodium*, *potassium*, *ammonium*, *magnesium*, and *calcium sulphites*. *Sodium* and *potassium sulphites* are official, and will be found treated of in the first part of the *Dispensatory*.

Ammonium sulphite may be prepared in the same way,—that is, by passing sulphurous acid through a solution of the ammonium carbonate. When the carbonate is insoluble, as in the case of magnesia and lime, it is better to have recourse to the method of double decomposition; but the calcium sulphite may be prepared by using lime water for the saturation of the sulphurous acid. Whenever evaporation is employed, it should be carefully conducted so as not to drive off the acid, and with as little exposure to the air as possible, as the sulphites in solution are strongly disposed to pass into sulphates. Even in the solid state they slowly undergo the same change, and should therefore be kept, as far as can be conveniently done, excluded from the air. The sulphites in general have a mild sulphurous taste, and on exposure to heat, or with the addition of an

acid, emit the characteristic odor of sulphurous acid. They are distinguishable from the *hyposulphites* or *thiosulphates* by not depositing sulphur on the addition of dilute sulphuric acid to their solution. As the efficiency of the sulphites is ascribable to their acid, they may be used indiscriminately, one being preferred to another according to solubility, or other property affecting the convenience of exhibition.

Sodium, magnesium, and *potassium sulphites* have been fully described, and the remarks in reference to their therapeutical application may be considered as applicable to the others. *Ammonium sulphite,* $(NH_4)_2SO_3$, has an acrid sulphurous taste, at first deliquesces in the air, and afterwards dries, gradually being converted into the sulphate by the absorption of oxygen. It is soluble in its weight of cold, and in less than its weight of boiling water. It decrepitates with heat, losing a part of its ammonia, and then sublimes as an acid sulphite. *Calcium sulphite,* $CaSO_3$, is a white powder, and distinguished by its difficult solubility, requiring 800 parts of water for solution. An excess of acid renders it more soluble; and from its hot saturated solution it is deposited, on the cooling of the liquid, in hexagonal needles.

The influence of these salts on the system in health is feeble. Six drachms have been taken in twenty-four hours, without injury. When taken internally, they are absorbed, and partly eliminated unchanged with the urine, partly changed by the absorption of the oxygen into sulphates, as happens on exposure out of the body, the urine at first containing a sulphite, and after twenty-four hours a sulphate. From the largest doses of the sulphites only a laxative effect and an increased secretion of the urine are obtained. Their long-continued use is said to prove injurious, by inducing debility and anæmia. From fifteen grains to a drachm (0·9–3·9 Gm.) may be given, so repeated as to amount to from two drachms to an ounce in twenty-four hours. As almost all acids decompose the sulphites, they should not be administered with any acid substance. Should the bowels be disturbed, a little of some opiate may be given. For external use, one part of the salt employed may be dissolved in from five to ten parts of water.

Acid Sulphites (*Bisulphites*). These are quite as efficient as the sulphites, probably more so, in consequence of their relatively greater proportion of acid. They might be and probably are used indiscriminately with the sulphites; as, in the preparation of the latter by the direct union of their constituents, the sulphurous acid may readily be used in excess, and thus give rise to the bisulphite. Indeed, Berzelius states that the salt formed by passing sulphurous acid through a solution of sodium carbonate until the liquid shall sensibly redden litmus paper, is really sodium bisulphite; and that the sulphite may be prepared by adding to this salt a quantity of soda equal to that already contained in it. The bisulphites generally may be prepared by passing sulphurous acid in excess through the alkaline solution, or through the solution of a sulphite already formed. (See also *P. J. Tr.*, 1872, 844.) They may be distinguished from the sulphites by being quite neutral to test-paper, while the latter salts have a feeble alkaline reaction. They may be given for the same purposes and in the same dose and method of administration as the sulphites. Some years since (*P. J. Tr.*, 1867), W. Lascelles Scott called attention to the *calcium bisulphite* as a very valuable preservative; but his statements have not led to the practical use of the drug.

Hyposulphites (*Thiosulphates* or *Sulpho-sulphates*). These may be considered as absolutely identical for therapeutic purposes with the sulphites; as, when they undergo decomposition, sulphurous acid is eliminated. The hyposulphites consist of bases combined with an acid, which, in the free state, would be $H_2S_2O_3$, but which, when liberated, separates into sulphurous acid and sulphur. They are prepared by boiling a sulphite or bisulphite in solution with sulphur, as in the example of sodium thiosulphate, $2Na_2SO_3 + S_2 = 2Na_2S_2O_3$, or on a larger scale by passing sulphur dioxide into the calcium sulphide liquor of the alkali waste, whereby calcium thiosulphate is formed. This may then be changed into the sodium salt by the action of sodium sulphate yielding sodium thiosulphate and calcium sulphate. The chief advantage possessed by the hyposulphites is that they are less disposed than the sulphites to change into sulphates by the absorption of oxygen. They may be recognized by the deposition of sulphur when an acid is added to their solution. They are freely soluble in water, even the calcium and magnesium hyposulphites. They may be used for the same purposes and in the same doses as the sulphites, and administered in the same way.

SULPHORICINIC ACID. This is made by the action of from 30 to 40 per cent. sulphuric acid upon castor oil at a temperature not exceeding 50° C., care being taken to avoid the evolution of sulphur dioxide. On the addition of water, the sulphoricinic acid with unchanged oil separates in an oily layer from the aqueous solution of acid below. The *sodium sulphoricinoleate* forms a brown liquid, miscible with water and alcohol.

This substance is a powerful local irritant. M. Berlioz states that the acid and its soluble salts are actively antiseptic and deodorizant; useful as a local application in *ozæna* and other affections. (*La Sem. Méd.*, March 11, 1891.) The salts have the power of dissolving powerful antiseptic substances. In this way has been prepared and offered for sale *Phenolum Natrio-sulphoricinicum.* This is a yellowish liquid, containing 20 per cent. of carbolic acid and 80 per cent. of sodium sulphoricinate. The liquid itself mixes in all proportions with water, and has been especially commended as a local application in various *diseases of the skin* and in *tubercular* and other *ulcerations of the mucous membranes.* Berlioz (*Bull. Gén. de Thérap.*, 1890) especially recommends it in *diphtheria.* The 20 per cent. aqueous solution is to be applied locally to the throat four times a day and once or twice in the night. (*La Sem. Méd.*, 1892.) The *Naphtol sulphoricinate*, the *Salol sulphoricinate*, and the *Creosote sulphoricinate* have also been made and used as local agents.

SUPRARENAL BODIES. In no portion of physiology is there at present more uncertainty of knowledge and activity of research than in regard to the functions of the suprarenal bodies. Two theories have been strenuously upheld,—one that these bodies have for their function the destruction of certain poisons, and that the substances found in them have been gathered out from the blood for the purposes of removal; the other that the suprarenal bodies produce a very active substance necessary for the health of the organism. Which-

ever of these theories be correct, it seems established that the suprarenal bodies do contain in them a substance of remarkable physiological activity. This principle has been isolated by John J. Abel, of Johns Hopkins University, and called *epinephrin*. It was obtained as a powder of from a light gray to a brownish color, showing the composition $C_{17}H_{15}NO_4$. When treated with powdered alkalies, it splits off a primary amine and skatol (or methyl indol). Salts of the base, such as benzoate, acetate, sulphate, and picrate, have been obtained and analyzed.

A minute dose of the suprarenal extract given intravenously produces an enormous rise of the arterial pressure, which has been shown by Oliver and Schäfer (confirmed by Velich, Biedl, and Fraenkel) to occur after section or destruction of the medulla oblongata, and therefore to be due to a direct action of the extract upon the muscles of the blood-vessels and of the heart. When given in toxic dose, the extract causes in mammals rapid and extreme enfeeblement, with failure of respiration and of the circulation. Vincent has noted that the moderate dose of the extract produces in the lower animals an enormous increase in the respiratory rate, so that the extract probably is both a respiratory and a circulatory stimulant.

The first use of the suprarenal extract in practical medicine was for the relief of *Addison's disease*, and sufficient clinical experience has been accumulated to make it imperative upon the physician in any case of Addison's disease to make proper trial of the extract. The proper dose of the extract cannot yet be considered as determined, but is small. We have used a glycerin extract (forty grains of the gland to one fluidrachm), in doses of from ten to fifteen minims (0·7–1 C.c.) hypodermically, with success. Oliver has given one hundred and twenty grains of the dried, equal to six hundred grains of the fresh, gland daily for a week without producing any evidence of intoxication. If convalescence has been obtained in Addison's disease by the use of the suprarenal extract, the administration of the extract in small quantities must be continued for a great length of time. (See *Thyroid Extract.*)

The physiological action of the suprarenal extract gives reason for hope that it will prove to be a very important remedy in all cases in which there is failure of the heart, and especially of the blood-vessels, but actual experience with it at present is very slight. Huchard states that he has obtained excellent results in *neurasthenia* from the use of from fifteen to thirty grains of the gland daily.

Mankowski found that dogs which had been chloroformed until circulation and respiration had practically ceased were at once restored by the immediate injection of a suprarenal extract solution into the jugular vein, whilst Gottlieb obtained similar results in chloralized dogs. This experience would indicate that the remedy is probably of great value in acute *cardiac failure*, from chloroform or other cause, and should also be of service in all cases in which the vaso-motor tone is lost. At present, however, there is no sufficient clinical experience to act as a guide in this matter. Moreover, the practical value of the remedy is made very doubtful by the fact, first noticed by Cybulski, that it acts very fugaciously under all circumstances, and very feebly when given otherwise than intravenously. In the experiments of Gottlieb it was found that the suprarenal extract has no effect upon the blood-pressure when administered by the mouth; and that even twenty times the usual intravenous dose given hypodermically did not distinctly affect the circulation of the dog. The cause of this failure Gottlieb (*Archiv f. Exper. Path. u. Pharm.*, Bd. xxxviii. 100) believes to be due to a destruction of the active principle of the drug in the tissues, because Cybulski found that the action of the extract was not lessened by tying the renal arteries. On consulting Cybulski's original paper, however, we have been unable to find any such statement; on the contrary, that investigator asserts (*Wiener Med. Wochenschrift*, xlvi., 1896, 258) that the active principle is quickly thrown off from the kidney; basing this assertion on the fact which he has experimentally determined that, unlike the urine of the normal dog, the urine of the poisoned animal yields an extract which acts similarly to the pure suprarenal extract in the normal dog. Cybulski has also determined that defibrinated arterial blood does not destroy the extract when mixed with it. Rapid elimination is therefore probably the chief cause of the fugaciousness of the influence of the suprarenal capsules extract, although, as Cybulski determined that a solution of the potassium permanganate quickly destroys it, so it would seem possible that the active principle is oxidized in the system to some extent.

It would be evidently useless to inject an extract of suprarenal capsules, almost of necessity containing microbes, into the vein of a human being, so that the value of suprarenal extract as a cardiac stimulant seems at present to be very low. If, however, the stimulant principle of the suprarenal extract should become a commercial product in its pure form, it would probably be of the greatest value in various cases of sudden heart-failure. If the results obtained in Addison's disease by the administration of the suprarenal extract be as is believed, it is very probable that the extract contains some other principle than that which affects the circulation.

The influence of the suprarenal extract upon the blood-vessels is so intense that it will probably prove to be a local remedy of importance in various inflammatory and congestive diseases. Velich (*Wien. Med. Blätter*, 1897) found that a sterilized aqueous solution of suprarenal extract produced when dropped in the eye marked pallor, and that in various conditions with granulating surfaces a similar local influence was manifested. In cases of *eczema*, under the action of the solution the red hyperæmic skin becomes white, provided the disease has not been of such long standing as to impair the activity of the blood-vessels. These observations, at least so far as the eye is concerned, have been confirmed by Darier, by Dor, by Maurange, and others. In the eye the pallor appears in from thirty to forty seconds, and lasts from fifteen to twenty minutes. Maurange strongly recommends an aqueous extract for the prevention of hemorrhage during operations on the eye, as a hæmostatic, and as an assistant to the usual method of treatment in *conjunctivitis*, *keratitis*, *glaucoma*, and other ocular inflammation. It is important that the solution be made fresh at the time of using, as it undergoes rapid decomposition. It should always be sterilized by boiling just before it is used.

SWEET PELLITORY. The root of *Tanacetum unbelliferum*, Boiss. (nat. ord. Compositæ), of India, according to David Hooper, contains pyre-

thrine in minute proportions with fat and wax, an organic acid which is a pigment, glucose, and inulin. (*P. J. Tr.*, xxi. 1890.)

SWIETENIA FEBRIFUGA. Roxb. (Now *Soymida febrifuga*, Juss.) *Rohun-bark.* (Nat. ord. Meliaceæ.) The bark of this East Indian tree is said to be much used as an antiperiodic in half-drachm (1·9 Gm.) doses.

The *Swietenia mahagoni*, Jacq., or *mahogany-tree*, which grows in the West Indies and other parts of tropical America, has also a bitter, astringent bark, containing catechin. (*Bull. Soc. Chim. de Paris*, xxiv. 118.) The bark of *S. senegalensis*, Desv. (now *Khaya senegalensis*, A. Juss.), is used on the coast of Africa in the cure of *intermittents*, and M. Caventou has extracted an alkaloid from it. (*Am. Journ. Med. Sci.*, N. S., xx. 168.)

SYCOSE. This name has been applied to saccharin and also to preparations of saccharin. (See *Glusidum*, p. 654.)

SYMPHOROL. *Symphoral*, *Sodium*, *Lithium*, or *Strontium Caffeine-sulphonates.* The name symphorol is applied to either of the salts above mentioned. They are colorless, odorless, bitter powders. The sodium salt is used as a diuretic, the lithium salt in *gout* and *rheumatism*, and the strontium salt in *Bright's disease.*

SYMPHYTUM OFFICINALE. L. *Comfrey. Radix Symphiti. Radix Consolidæ Majoris. Consoude*, Fr. *Schwarzwurz*, *Beinwurz*, G. A perennial European plant often cultivated. Its root is spindle-shaped, branched, often more than an inch thick and a foot long, externally smooth and blackish, internally white, fleshy, and juicy. By drying it becomes wrinkled, of a firm, horny consistence, and of a dark color within. It is almost inodorous, and has a mucilaginous, feebly astringent taste. It contains mucilage in great abundance (according to Lewis, more than althæa root) and a little tannin. It was formerly highly esteemed as a vulnerary. Its virtues are those of a demulcent, like marshmallow, and it is used domestically in *chronic catarrhs*, *consumption*, and other lung diseases.

SYMPLOCOS RACEMOSA. Roxb. (Nat ord. Styraceæ.) The bark of this East Indian tree is said to be a mild astringent, and especially useful in *menorrhagia.* (*P. J. Tr.*, Sept. 24, 1881.)

SYNANTHROSE. *Lævulin.* $C_6H_{10}O_5$. This is a carbohydrate, isomeric with inulin, discovered by O. Popp in *Helianthus tuberosus*, L. (Nat. ord. Compositæ.) For details, see Tollens, *Kohlenhydrate*, 198.

SYRINGA VULGARIS. L. *Common Lilac.* (Nat. ord. Oleaceæ.) The leaves and fruit of this common garden plant have a bitter and somewhat acrid taste, and have been used as tonic and antiperiodic. MM. Petroz and Robinet found in the fruit a sweet and bitter principle. The latter was afterwards obtained pure by M. Meillet, who gave it the name of *lilacin*, and by Bernays, who called it *syringin.* It has been investigated by Kromayer (*Arch. d. Pharm.*, (2) 118, 19), who established its glucosidal character, gave it the formula $C_{17}H_{24}O_9 + H_2O$, and showed its identity with the *ligustrin* of Polex. It forms long white stellate needles, which are tasteless, easily soluble in hot water and alcohol, insoluble in ether. The crystals become anhydrous at 115° C., and fuse at 212° C. On heating with dilute acids it breaks up into *syringenin*, $C_{11}H_{14}O_4$, and a fermentable glucose. The *syringenin* (which has been recognized as *oxymethyl coniferin*) is a light rose-red amorphous mass, soluble in alcohol, insoluble in water and ether.

SYRUPUS FERRI BROMIDI. *U. S.* 1880. *Syrup of Bromide of Iron.* "A syrupy liquid containing 10 per cent. of Ferrous Bromide [$FeBr_2$; 215·5.—FeBr; 107·75]. Iron, in the form of fine wire, and cut into small pieces, *thirty parts* [or one and a half ounces av.]; Bromine, *seventy-five parts* [or nine fluidrachms]; Sugar, in coarse powder, *six hundred parts* [or twenty-eight ounces av.]; Distilled Water, *a sufficient quantity*, To make *one thousand parts* [or about two pints]. Introduce the Iron into a flask of thin glass of suitable capacity, add to it *two hundred parts* [or nine fluidounces] of Distilled Water and afterwards the Bromine. Shake the mixture occasionally, until the reaction ceases and the solution has acquired a green color and has lost the odor of Bromine. Place the Sugar in a porcelain capsule and filter the solution of bromide of iron into the Sugar. Rinse the flask and Iron wire with *ninety parts* [or four fluidounces] of Distilled Water, and pass the washings through the filter into the Sugar. Stir the mixture with a porcelain or wooden spatula, heat it to the boiling point on a sand-bath, and, having strained the Syrup through linen into a tared bottle, add enough Distilled Water to make the product weigh *one thousand parts* [or measure two pints]. Lastly, shake the bottle and transfer its contents to small vials, which should be completely filled, securely corked, and kept in a place accessible to daylight." Although this ferruginous syrup is not so sensitive to the oxidizing action of the air as syrup of iodide of iron, it is preferable to filter the solution into hot syrup instead of into sugar in an open capsule. It is "a transparent, pale green liquid, odorless, having a sweet, strongly ferruginous taste, and a neutral reaction. With test-solution of ferricyanide of potassium it yields a blue precipitate. If a little disulphide of carbon be added to the syrup, then a few drops of chlorine water, and the whole agitated, the disulphide will separate with a yellow or brown color. It should not deposit a sediment on keeping, and should not tinge gelatinized starch yellow (abs. of free bromine). 5·39 Gm. of the Syrup should require for complete precipitation 50 C.c. of the volumetric solution of nitrate of silver (corresponding to 10 per cent. of ferrous bromide)." *U. S.* 1880. Ferrous bromide has been recommended as a sedative chalybeate tonic, and has been especially praised by Jacob Da Costa in *chorea.* In an extended trial of it by H. C. Wood, it failed entirely to be of service. It is not an eligible chalybeate. Dose, from half to one fluidrachm (1·9–3·75 C.c.), equal to about four to eight grains of the bromide.

TACAMAHAC. *Tacamahaca.* The resinous substance commonly known by this name is supposed to be derived from the *Fagara octandra* of Linn. (*Elaphrium tomentosum*, Jacq., *Amyris tomentosa*, Spreng., now *Bursera tomentosa*, Triana and Planch.), a tree of considerable size, of the nat. ord. Burseraceæ, growing in the island of Curaçoa and in Venezuela. The juice exudes spontaneously, and hardens on exposure. As brought into the market, it is in irregularly shaped pieces of various sizes, some not larger than a mustard-seed, others as much as an inch or two inches in diameter. The color is usually light yellowish or reddish brown, but in the larger masses is more or less diversified. The pieces are in general translucent,

though frequently covered with powder upon their surface, so as to render them apparently opaque. They are heavier than water, brittle, and pulverizable, yielding a pale yellow powder. Their odor is resinous and agreeable, their taste bitter, balsamic, and somewhat acrid. Exposed to heat, they melt and exhale a stronger odor. Tacamahac is partially soluble in alcohol, and completely so in ether and the fixed oils. It consists of resin with a little volatile oil.

Another variety is obtained from the East Indies, and called *tacamahaca orientale*, or *tacamahaca in testis* It is supposed to be derived from the *Calophyllum inophyllum*, and comes into the market in gourd-shells covered with rush leaves. It is of a pale yellow color inclining to green, slightly translucent, soft, and adhesive, of an agreeable odor, and an aromatic bitterish taste. It is at present very rare in commerce. The tree which yields this resin produces a drupe, about as large as a plum, from the seeds of which 50 per cent. of a greenish-yellow fixed oil is obtained by expression, used in India for lamps, and as a local application in the *itch*. (*Journ. de Pharm.*, 1861, 23.) Guibourt describes several other varieties of tacamahac, which, however, are little known. Among them is a soft, adhesive, dark green oleoresin (*Journ. de Pharm.*, 3e sér., xxiv. 396), said to be procured from the *Calophyllum tacamahaca*, growing in the islands of Bourbon and Madagascar. (See also Pennetier, *Matières Premières*, 642.)

Tacamahac was formerly highly esteemed as an internal remedy, but is now used only in ointments and plasters. Its properties are analogous to those of the turpentines. It is sometimes used as incense.

TAKA-DIASTASE. This ferment is formed by the action of a fungus (*Moyashi aspergillus oryzæ*, Cohn. *Eurotium oryzæ*, Ahlburg; for description, see *A. J. P.*, 1898, 137) upon steamed rice, and is used in Japan, where it is known by the name of *koji*, in the preparation of the national intoxicating beverage *sake*. It has also been employed to act upon maize in the making of whiskey. It is a yellowish-white, highly hygroscopic powder, almost tasteless, freely soluble in water. It is capable, under proper conditions, of converting one hundred times its weight of starch in ten minutes into glucose. Its action resembles very closely that of saliva; according to the experiments of Julius Friedenwald (*New York Med. Journ.*, 1897), it not only aids in the digestion of the starches, but serves the other function of the saliva in stimulating the gastric secretion, and thereby promoting the proteid digestion. It would seem, therefore, to be especially indicated as an artificial digestant in those cases in which there is a deficiency of saliva.

There is much clinical evidence on record as to its value in all cases in which there is loss of power of digesting starches, and the correctness of Armstrong's assertion (*Liverpool Med. Chir. Journ.*, 1897), that it is especially valuable in gouty persons in whom the starch digestion is often feeble, would seem to be well founded. In Friedenwald's experiments with test-breakfasts it was found not to affect normal gastric digestion, and to be of very little value in pure *nervous dyspepsia*. In cases of *gastric catarrh*, with subacidity, it appeared to have a tendency to increase the acidity of the gastric juices and to promote the digestion of starches. Its greatest applicability, however, was found to be in cases of hyperacidity, in which it is stated to diminish the excess of acid and increase gastric peristalsis. It should be given in the middle of the meal, in doses of from five to ten grains (0·3–0·6 Gm.), in capsules; or, after the meal, in slightly alkaline solution.

TALCUM. $4MgO.5SiO_2.H_2O$. *Talc. French Chalk.* This mineral is known also as *steatite* or *soapstone*, yet, strictly speaking, the latter differs slightly, having aluminum in its composition. Talc is a very widely diffused substance, having been found in Austria, Shetland Isles, Sweden, Bohemia, New Jersey, and in various other countries. It is of a whitish or grayish-green color, having a waxy lustre, and occurs in masses, which cleave perfectly in one direction. Its sp. gr. is 2·6, and pure talc is insoluble in acids and other liquids. Ferrous oxide and small quantities of alumina and lime are frequently found associated with it. When powdered and purified from these contaminations by treatment with a hot dilute solution of hydrochloric acid, it forms an excellent filtering basis. The production of talc and soapstone in the United States is large. The entire product of the various grades of talc marketed during 1892 is estimated at about 70,000 tons, of which 51,000 tons were fibrous talc and 19,000 tons were soapstone.

TANGHINIA. *Ordeal Bean of Madagascar. Tanghinia venenifera*, Poir. (now *Cerbera Tanghin*, Hook.) (nat. ord. Apocynaceæ), has been investigated, and, according to C. E. Quinquaud, is both a respiratory and a cardiac poison. (*Compt.-Rend.*, cl. 534. See also *Therap. Gaz.*, vol. ii. 610.) The active principle, *tanghinin*, occurs in colorless lustrous scales, efflorescing in the air, having a bitter and sharp taste, soluble in alcohol, ether, and acetic acid.

TANNALBIN. *Tannin Albuminate.* This compound, suggested by Gottlieb, is made by adding to ten parts of a 10 per cent. solution of albumen six and a half parts of a 10 per cent. solution of tannin; the precipitate is collected, washed, pressed, and dried by exposure to heat (about 110° C.) for six hours. It contains about one-half its weight of tannin. It is a light brown powder, insoluble in water and in the gastric juice, tasteless, odorless, and not at all irritant to the mucous membranes. As an astringent it is very feeble, but is probably decomposed in the intestines, and is a valuable remedy in the treatment of *chronic diarrhœa* dependent upon intestinal relaxation, and has even been used with asserted satisfaction when there were intestinal catarrh and ulceration. It does not disturb the digestion: indeed, has been highly commended in *gastric catarrh* with excessive secretion of mucus. It has also been found useful in *chronic albuminuria*, especially in lessening the amount of albumin in the urine. Dose, from fifteen to thirty grains (0·9–1·9 Gm.), three to six times a day, in capsule or powder.

TANNALUM. *Tannal. Basic Aluminum Tannate.* $Al_2(OH)_4(C_{14}H_9O_9)_2 + 10H_2O$. This is a brownish-yellow powder, insoluble in water, which has been especially commended by Heymann as a mild, astringent, non-irritant substance, to be used as a dusting powder or by insufflation in diseases of the nasal and laryngeal mucous membranes. By the action of tartaric acid it becomes converted into the so-called *soluble tannal*, $Al_2(C_4H_6O_6)_2(C_{14}H_9O_9)_2 + 6H_2O$, also used locally.

TANNIGEN. *Diacetyl Tannic Acid.* $C_{14}H_8(COCH_3)_2O_9$. This compound, which is prepared

by the action of acetic anhydride or acetyl chloride upon tannin, is the acetic ester of tannic acid. It is a yellowish-gray, tasteless and odorless, slightly hygroscopic powder, which can be heated to 180° C. without alteration; insoluble in cold water, readily soluble in alcohol, dissolving in dilute solution of sodium phosphate, soda, or borax, with the production of a yellowish-brown color. It has been used as a mild astringent in chronic *diarrhœas*, especially in such as often accompany *phthisis*, and as a local application by insufflation in chronic *rhinitis* and *laryngitis*. Dose, from ten to fifteen grains (0·6–0·9 Gm.) three or four times a day, in capsules: to children it may be given spread on bread and butter.

TANNOFORM. *Methylene Ditannin.* $CH_2(C_{14}H_9O_9)_2$. A new class of bodies has been prepared by Merck which are termed tannoforms, and which consist of combinations between the various characteristic tannins and formaldehyde. These bodies are formed by adding a solution of formaldehyde gas to a purified plant extract containing the plant tannin in the presence of hydrochloric acid. The further nomenclature of the tannoforms depends upon the name of the plant from which the particular tannin is derived.

The condensation product of gallotannic acid and formaldehyde, which is termed simply tannoform, is made by dissolving five grammes of tannin in about fifteen kilogrammes of hot water, adding three kilogrammes of 30 per cent. formaldehyde, and then adding concentrated hydrochloric acid until no further precipitate is thrown down. This requires about twelve to fifteen kilogrammes of acid. The precipitate is then washed with water and dried at a low temperature.

Tannoform occurs as a light pinkish-white powder which decomposes at about 230° C. It is dissolved by alcohol and is insoluble in all the usual organic solvents; but is soluble in diluted ammonia, soda, or potassa solutions, giving a brownish-red solution, from which it is again precipitated upon the addition of an acid. When warmed with concentrated sulphuric acid it dissolves with a brown color, turning on further heating to green, and then to blue. The green or blue sulphuric acid solution gives a beautiful blue color with alcohol, which on standing some time turns to a wine-red, and on dilution with soda solution to a grass-green color. Tannoform is looked upon as being *methylene ditannin*. It has been chiefly used as a local remedy in the treatment of *eczema*, *bed-sores*, *local hyperidroses*, *chancres*, etc. Von Oefele recommends it especially in *pruritus vaginæ*. It may be used as a dusting powder pure, or often with advantage mixed with starch.

It is stated that tannoform is decomposed in the intestines by the pancreatinic juices, and acts as an astringent through its tannic acid, and as an antiseptic through its formaldehyde. It has been used with alleged good result in acute and chronic *enteritis* and other forms of *diarrhœa*, in doses of from one-half grain to one grain (0·03–0·06 Gm.), in capsule, from three to six times a day.

TANNON. *Tannopin*, $(CH_2)_6N_4(C_{14}H_{10}O_9)_3$, is a condensation product of tannin and hexamethylenetetramine (urotropine). It is a light brown, tasteless and odorless, non-hygroscopic powder, insoluble in water, weak acids, spirit, and ether, but dissolving slowly in dilute alkaline solution. It has been used by Schreiber (*Deutsche Med. Wochensch.*, 1897) in *diarrhœa* in doses of fifteen grains (0·9 Gm.) from three to four times a day.

TANNOSAL. *Creosal.* The tannic acid ester of creosote, containing 60 per cent. of creosote. This is an amorphous dark brown powder, having a slight odor of creosote and a disagreeable taste; very hygroscopic, and soluble in water, alcohol, and glycerin. It is a synthetic combination of tannic acid and creosote in the proportion of two to three, and has been commended by G. Kestner (*Therap. Wochensch.*, Bd. x.) in the treatment of *tuberculosis* and *pulmonary catarrhs*. Dose, from fifteen to sixty grains (0·9–3·7 Gm.). The commercial solution of tannosal contains fifteen grains (0·9 Gm.) in each tablespoonful.

TAPIOCA. Under this name the U. S. P. formerly recognized the fecula obtained from the *Janipha manihot*, H. B. K., *Jatropha manihot*, L. (now *Manihot utilissima*, Pohl, B. & T. 235), the *cassava* plant or *manioc* of the West Indies, the *mandioca* or *tapioca* of Brazil. It is a shrub belonging to the Euphorbiaceæ, about six or eight feet high, with a very large, white, fleshy, tuberous root, which often weighs thirty pounds. The stem is round, jointed, and furnished at its upper part with alternate petiolate leaves, deeply divided into three, five, or seven oval-lanceolate, very acute lobes, which are somewhat wavy upon their borders, deep green on their upper surface, glaucous and whitish beneath. The flowers are in axillary racemes.

Janipha manihot is a native of South America, and is cultivated extensively in the West Indies, Brazil, and other parts of tropical America, and in Liberia, for the sake of its root, which is much employed as an article of food. It can also be grown successfully in Florida and other Southern States. (See *Forty-fourth Bulletin U. S. Dept. Agriculture.*) The plant is propagated by cuttings. It is of quick growth, and the root arrives at perfection in about eight months. There are two chief varieties, but it is said that in Brazil as many as thirty different forms of the plant are recognized by cultivators. The root of the *sweet* cassavas may be eaten with impunity; that of the *bitter*, which is the most extensively cultivated, abounds in an acrid milky juice, which renders it highly poisonous if eaten in the recent state. By MM. Henry and Boutron-Chalard it has been ascertained that the bitter cassava owes its poisonous properties to hydrocyanic acid. (*Journ. de Pharm.*, xxii. 119.) Both varieties contain a large proportion of starch. The root is prepared for use by washing, scraping, and grating or grinding it into a pulp, which, in the bitter variety, is submitted to pressure so as to separate the deleterious juice. It is dried, and in the state of meal or powder is made into bread, cakes, or puddings. As the poisonous principle is volatile, the portion which may have remained in the meal is entirely dissipated by the heat employed in cooking. The preparation denominated tapioca among us is obtained from the expressed juice. This, upon standing, deposits a powder, which, after repeated washings with cold water, is nearly pure starch. It is dried by exposure to heat, which renders it partially soluble in cold water, and enables it to assume its characteristic consistence. When dried without heat, it is pulverulent, and closely resembles the fecula of arrow-root. In Demerara, as we are told by M. Pagot, the manioc

juice, after having been deprived of all injurious properties by boiling, is used as a sauce. (*P. J. Tr.*, 1873.)

The preparation of tapioca in Malacca is thus described by James Collins. The fresh root-stocks were thoroughly washed in tubs in a constant stream of water by scantily clad Chinese, and then peeled like turnips; they were then sliced in one machine and pulped in another, the pulp being removed in cane baskets to large wooden frames, with calico bottoms; a powerful stream of water was allowed to fall upon the pulp, a sifting motion being communicated to the strainer; as the starch became washed out, it was received into inclined troughs, and, whilst in a state of suspension, run into settling-vats. There it was stirred and washed, and, while moist, it was removed to the drying-room. Two kinds of tapioca are prepared. The flour is made by heating slightly by fires placed underneath; it is constantly stirred, and turned over with iron shovels, to prevent agglutination and insure equal drying. Granular tapioca is made as follows. A long range of quallies, or small iron shallow pans, are slightly tilted forward on ledges of brickwork, and heated with a wood fire. Each operator has a quallie and fire to himself. Taking a quantity of damp starch, he stirs it round and round with an iron shovel, and the heat is sufficient to cause the tapioca to become agglutinated together in small masses, and coated with dextrin. The drying is done with great skill, and with an open fire. (*Chem. and Drug.*, 1884.) Tapioca is also made at present on the large scale in Malacca with steam apparatus.

Tapioca is in irregular, hard, white, rough grains, possessing little taste, partially soluble in cold water, and affording a fine blue color when iodine is added to its filtered solution. The partial solubility in cold water is owing to the rupture of the starch-granules by heat. Examined under the microscope, the granules appear partly broken, partly entire. The latter are muller-shaped, about the two-thousandth of an inch in diameter, more uniform in size than the granules of most other varieties of fecula, with a distinct hilum, which is surrounded by rings, and cracks in a stellate manner. *Tapioca meal*, called sometimes *Brazilian arrow-root*, and by the French *moussache*, is the fecula dried without heat. Its granules are identical with those already described. Being nutritious, and at the same time easy of digestion and destitute of irritating properties, tapioca forms an excellent diet for the sick and convalescent. It is prepared for use by boiling it in water. Lemon-juice and sugar are usually grateful additions, and in *low states of disease* or cases of *debility* it may be advantageously impregnated with wine and nutmeg or other aromatic.

A factitious tapioca is found in the shops, consisting of very small, smooth, spherical grains, and supposed to be prepared from potato starch. It is sold under the name of *pearl tapioca*.

From the *Zamia integrifolia* (nat. ord. Cycadaceæ) or *Indian bread-root* of South Florida the Seminole Indians produce a yellowish-white flour known as *koonti*, and much used by them. From the same root it is said that a very superior edible starch is manufactured and sold in Key West. The starch grains are muller-shaped. (See *A. J. P.*, 1898, 212).

TAXUS BACCATA. L. *Common European Yew-tree. If commun*, Fr. *Eibe*, G. (Nat. ord. Coniferæ.) The fruit of this handsome and well-known evergreen appears to be a deadly poison. In a fatal case the child was found semi-comatose, with convulsions, a cold and clammy skin, difficult respirations, dilated pupils, and attempts at vomiting. There seems to be reason for believing that the poison is in the seeds rather than the flesh of the berry. (See 16th ed. *U. S. D.*; also Dr. James Thompson, *Lancet*, 1868, 530. For fatal cases in adults, see *Med. Times and Gaz.*, 1870, ii.; also *Lancet*, 1870, 471; also *P. J. Tr.*, viii. 361.) W. Marmé obtained from yew seeds and leaves an alkaloid, $C_{37}H_{51}NO_{10}$, to which the name of *taxine* has been given. It was a white, poisonous, crystalline powder, slightly soluble only in water, easily soluble in ether, alcohol, chloroform, benzol, and carbon disulphide, but not in petroleum benzin. It fused at 80° C. With concentrated sulphuric acid it gave a red color, but dissolved without color in nitric and phosphoric acids. (*A. J. P.*, 1876, 353.) For Vreven's method of isolating toxine, see *P. J. Tr.*, 1896, 215. Amato and Capparelli (*Gazz. Chim.*, x. 349) prepared from the leaves a volatile alkaloid, which was soluble in cold sulphuric acid with yellow color, becoming red on heating. They also isolated a nitrogenous crystalline and colorless principle, fusing at from 86°–87° C., soluble in alcohol and insoluble in water, to which they gave the name *milossin*.

TAYUYA. The root of the *Dermophylla pendulina*, Manso (nat. ord. Cucurbitaceæ) is used in Brazil, under the name of *tayuya*, in *syphilis*, etc. (*N. R.*, 1877, 234); also, under the same name, the root of the *Trianosperma ficifolia*, Mart. (now *Cayapoina martiana*, Cogn.), also of the nat. ord. Cucurbitaceæ (*P. J. Tr.*, x. 667), and probably various other roots. In *T. ficifolia* two alkaloids, *trianospermine* and *trianospermitine*, and a bitter principle, *tayuyin*, have been found by Peckholdt (*P. J. Tr.*, x. 667), and in *T. dermophylla* a green resin, bitter extractive, and tannic acid. (*Bull. Gén. de Thérap.*, lxxxiv., xci. See also *Proc. A. P. A.*, xxiv.)

TEA. *Thé*, Fr. *Thee*, G. The plant which furnishes tea—*Thea chinensis*, Sims (*Camellia theifera*, Griff., now *C. Thea*, Link)—is an evergreen shrub belonging to the nat. ord. Ternstrœmiaceæ. It is usually from four to eight feet high, though capable, in a favorable situation, of attaining the height of thirty feet. It has numerous alternate branches, furnished with elliptical-oblong or lanceolate, pointed leaves, which are serrate except at the base, smooth on both sides, green, shining, marked with one rib and many transverse veins, and supported alternately upon short footstalks. They are two or three inches long, and from half an inch to an inch in breadth. The flowers are either solitary or supported, two or three together, at the axils of the leaves. They are of considerable size, not unlike those of the myrtle in appearance, consisting of a short green calyx with five or six lobes, of a corolla with from four to nine large unequal snow-white petals, of numerous stamens with yellow anthers and connected at their base, and of a pistil with a three-parted style. The fruit is a three-celled and three-seeded capsule. It has not been certainly determined whether more than one species of the tea-plant exist. Linnæus admitted two species—*T. bohea* and *T. viridis*—differing in the number of their petals; but this ground of distinction is untenable, as the petals are known to vary very much in the same plant. Hayne makes three species—

T. stricta, *T. bohea*, and *T. viridis*—which are distinguished severally by the shape of their leaves and fruit and the direction of the footstalk. De Candolle admits but one species, with two varieties,—the *viridis* or green tea, with "lanceolate flat leaves, three times as long as they are broad," and the *bohea*, with "elliptical-oblong, subrugose leaves, twice as long as broad." Lindley recognizes the two Linnæan species, distinguishing them by the leaves, which in *T. viridis* are acuminate, and emarginate at the apex, and in *T. bohea* are smaller, flatter, darker green, with small serratures, and terminate gradually in a point, but are not at all acuminate or emarginate. (*Flora Medica*, 120.)

The tea-plant is a native of China and Japan, and is cultivated in both countries, but most abundantly in the former. In Japan it forms hedge-rows around the rice- and corn-fields; in China, whence immense quantities of tea are exported, whole fields are devoted to its culture. It is propagated from the seeds, which are planted in holes at certain distances, six or eight seeds being placed in each hole, in order to secure the growth of one. In three years the plant yields leaves for collection, and in six attains the height of a man. When from seven to ten years old, it is cut down, in order that the numerous shoots which issue from the stump may afford a larger product of the leaves. These are picked separately by the hand. Three harvests, according to Kaempfer, are usually made during the year: the first at the end of February, the second at the beginning of April, and the third in June. As the youngest leaves are the best, the product of the first collection is most valuable, while that of the third, consisting of the oldest leaves, is comparatively little esteemed. Sometimes only one or two harvests are made; but care is always taken to assort the leaves according to their age, and thus originate numerous commercial varieties of tea. The character of the plant, dependent upon the soil, situation, climate, and culture, has also a great influence upon the value of the leaves. It is said that the best tea is procured from the shrubs which grow upon the sides of steep hills with a southern exposure. Though the plant grows both about Pekin in the north and Canton in the south of China, it is said to attain greater perfection in the intermediate country, in the neighborhood of Nankin, for instance, where the climate is neither so cold as in the first-mentioned vicinity nor so hot as in the second. Some of the commercial varieties have their origin in this cause; and it is highly probable, though the fact has not been certainly proved, that difference in species may be another source of diversity. After having been gathered, the leaves are dried by artificial heat in shallow iron pans, from which they are removed while still hot, and rolled with the fingers, or in the palm of the hand, so as to be brought into the form in which they are found in commerce. For further particulars as to the cultivation of tea, see *P. J. Tr.*, 1871, 386. The odor of the tea-leaves themselves is very slight, and it is customary to mix with them the flowers of certain aromatic plants, and those of the orange, different species of jasmine, the rose, *Olea fragrans*, Thunb. (now *Osmanthus fragrans*, Lour.), of the oleaceæ, and *Camellia sasanqua* (Thunb. ?), in order to render them pleasant to the smell. The flowers are afterwards separated by sifting or otherwise. (See *P. J. Tr.*, xv. 112.) The cultivation of tea has been successfully introduced into Brazil and into the British possessions in India. Samples of Himalaya tea, chemically examined by T. Zoeller, were found to be equal to the best Chinese product, containing at least 5 per cent. of theine and 5 38 per cent. of nitrogen. (*P. J. Tr.*, 1871, 162.) In 1886, England imported 145,000,000 lbs. of tea from China, and 81,000,000 lbs. from India. Attempts have been made, under the auspices of the government, to introduce the tea-culture into the United States.

Bush Tea and *Honig Thee*, used at Cape Colony, South Africa, as a substitute for tea, are the dried leaves and tops of species of *Cyclopia*, probably *C. brachypoda*, Benth. (now *C. subternata*, Vog.), and one or more species of *Cyclopia* (nat. ord. Leguminosæ). According to the analysis of Mr. Henry G. Greenish, they do not contain theine, but a glucosidal body, *cyclopin*, $C_{25}H_{28}O_{13}$. (*P. J. Tr.*, xi. 549.)

The importations of tea into the United States for the year ending June 30, 1897, amounted to 113,347,175 lbs., valued at $14,835,862. Numerous varieties exist in commerce, differing in the shape communicated by rolling, in color, in flavor, or in strength; but they may be all arranged in the two divisions of *green* and *black teas*, which, at least in their extremes, differ so much in properties that it is difficult to conceive that they are derived from the same species.

Under the name of *tea oil* has appeared in the London markets a Chinese fixed oil said to be derived from *Camellia oleifera*, Wall. (now *C. drupifera*, Lour.), a detailed description of which, with tests, may be found in the *P. J. Tr.*, vol. xvi. 634. A similar oil is prepared in Japan from the seeds of *Camellia japonica* (L. ?). (*Ibid.*, 637, 764.)

Properties. *Green tea* is characterized by a dark green color, sometimes inclining more or less to blue or brown. It has a peculiar, refreshing, somewhat aromatic odor, and an astringent, slightly pungent, and agreeably bitterish taste. Its infusion has a pale greenish-yellow color, with the odor and taste of the leaves. According to Mr. Warington, who examined numerous varieties of tea carefully, both by the microscope and chemical tests, many of the green teas imported into Great Britain owe their color to a powdery coating, consisting of calcium sulphate and Prussian blue; others to a mixture of these with a yellowish vegetable substance; and others, again, to calcium sulphate alone. (*P. J. Tr.*, iv. 37.) *Black tea* is distinguished by a dark brown color. It is usually less firmly rolled and lighter than the green, and contains the petioles of the plant mingled with the leaves. Its odor is fainter, and of a somewhat different character, though still fragrant. Its taste, like that of green tea, is astringent and bitterish, but is less pungent, and to many persons less agreeable. To hot water it imparts a brown color, with its sensible properties of taste and smell. These vary exceedingly in degree in the different varieties, and some black teas are almost wholly destitute of aromatic or agreeable flavor. According to Blyth, green tea is prepared from young leaves which are roasted over a wood fire within an hour or two after being gathered; while the black tea leaves, on the other hand, are allowed to lie in heaps for ten or twelve hours after they have been plucked, during which time they undergo a sort of fermentation; the leaves then pass through certain processes, and are slowly dried over charcoal fires. (Wynter Blyth, *Foods, Composition and Analysis*, 1882.) A sophisticated tea is largely exported from China,

consisting of powdered tea mixed with sand and other earth, and agglutinated with gum; that which is to pass for black being colored with plumbago, and the green with the coating above referred to. On analysis, these teas were found to afford from 35 to 45 per cent. of ashes, while the genuine yields only 5 per cent. A very full account of the adulteration of tea and the methods for the detection of the same may be found in Allen, *Com. Org. Anal.*, 2d ed.

The following analyses by Y. Kozai (Bulletin No. 7, Imperial College of Agriculture, Japan) have a special value, owing to the author's knowledge of tea manufacture. Special precautions were taken in sampling the leaves, to insure strictly parallel specimens being taken. The figures refer to the moisture-free leaves in each case.

	Unprepared Leaves.	Green Tea.	Black Tea.
Caffeine or Theine	3·30	3·20	3·30
Ether Extract	6·49	5·52	5·82
Hot-water Extract	50·97	53·74	47·23
Tannin or Gallotannic Acid	12·91	10·64	4·89
Other Nitrogen Free Extract	27·86	31·43	35·39
Crude Protein	37·33	37·43	38·90
Crude Fibre	10·44	10·06	10·07
Ash	4·97	4·92	4·93
Albuminoid Nitrogen	4·11	3·94	4·11
Caffeine Nitrogen	0·96	0·93	0·96
Amido-nitrogen	0·91	1·13	1·16
Total Nitrogen	5·97	5·99	6·22

Dr. Rochleder found also a peculiar acid, which he calls *boheic acid*, $C_7H_{10}O_6$. According to Stenhouse, the tannin of tea, though always accompanied by a little gallic acid, differs essentially from that of galls; not being, like it, a glucoside, but yielding, under the influence of sulphuric acid, a dark brown substance, almost insoluble in water. (See *A. J. P.*, 1862, 254.) For article on the methods of analysis of tea and a series of analyses of different varieties, see *A. J. P.*, 1887, 626. The volatile oil is citron-yellow, lighter than water, has a strong odor of the tea-plant, solidifies easily by cold, and resinifies on exposure to air. It is probably one of the principles upon which depend the effects of tea upon the nervous system. Hence old teas are less energetic than the recently imported; and it is said that the fresh leaves have often produced dangerous effects in China. Nevertheless, the tannic acid is not without influence upon the system; and it is not improbable that the extractive contributes to the peculiar influence of this valuable product. Of these active ingredients, the volatile oil, tannic acid, and extractive are found most largely, according to the analysis of Mulder, in the green tea. *Theine*, $C_8H_{10}N_4O_2$, is a crystallizable principle discovered by Oudry. It was afterwards proved by Jobst to have the same composition as caffeine. (See *Coffee*, *Ilex*, *Paullinia*, and *Sterculia acuminata*.) According to Mulder, it exists in tea combined with tannic acid. Theine has a feebly bitter taste; is, in the state of crystals, dissolved by 80 parts of water, 35 of alcohol, and slightly soluble in ether; melts at about 350° F., and at 185° C. (365° F.) sublimes in white vapors, which condense in minute needles. From its aqueous solution the following reagents precipitate it: phospho-molybdic acid, yellow precipitate; iodine with potassium iodide, dirty brown precipitate; platinum chloride, yellow hair-like crystals insoluble in cold hydrochloric acid, slowly separating; auric and mercuric chlorides and silver nitrate also give precipitates. Infusion of galls causes a deposit of theine tannate, which is again, however, dissolved by heating the water.

Tea is astringent and gently excitant, and exerts a decided influence over the nervous system, evinced by the feelings of comfort and even exhilaration which it produces, and the unnatural wakefulness to which it gives rise when taken in unusual quantities or by those unaccustomed to its use. It is almost exclusively used as a beverage. Taken moderately, and by healthy individuals, it may be considered as perfectly harmless; but long continued in excessive quantity it is capable of inducing unpleasant nervous and dyspeptic symptoms. Green tea is decidedly more injurious in these respects than black, and should be avoided by dyspeptic individuals, and by those whose nervous systems are peculiarly excitable. As a medicine, tea may sometimes be given advantageously in *diarrhœa*, and a strong infusion will often be found to relieve *nervous headache*. An extract is made from it in China which is said to be useful in fevers. (See *Extractum Camelliæ Fluidum*, National Formulary.)

TEGMIN. Under this name a surgical dressing has been recommended; it is an emulsion made from yellow wax, one part; acacia, two parts; water, three parts.

TELLURIUM. (Te. Atomic weight, 125.) Several of the combinations of this metal have been tried on the living organism by M. Hansen. Five grains of the *potassium tellurate*, given to dogs, produced stupefaction and vomiting, and the garlic-like odor of tellurium in the breath. The same salt, tried upon himself for seven successive days, in a dose daily of half a grain, afterwards increased to a grain, caused drowsiness at first, followed, after the seventh day, by a sense of oppression in the cardiac region, nausea, an increased flow of saliva, and loss of appetite. The breath had a garlic-like odor throughout the experiment. (*Chem. Gaz.*, 1854, 90.) Potassium tellurate has been very highly recommended for the prevention of *sweating*, given in doses of from one-sixth to one-half a grain (0.01–0·03 Gm.), in pill form. One-grain doses were found to disturb the stomach. (*Lancet*, March, 1892.) Simpson, of Edinburgh, relates the case of a student who inadvertently took a dose of tellurium, and exhaled so persistent an odor that he had to sit apart from his fellow-students. (See *Am. Journ. of Med. Sci.*, 1855, 496.) This disagreeable effect of tellurium precludes its employment in medicine.

TEPHROSIA VIRGINIANA. Pers. (Now *Cracca Virginiana*, L.) *Turkey Pea. Wild Pea. Cat-gut. Goat's Rue. Hoary Pea. Devil's Shoestring. Tephrosie*, Fr., G. (Nat. ord. Leguminosæ.) Several species of Tephrosia are employed in different parts of the world, though unknown in general commerce. They are leguminous plants, shrubby or herbaceous, with leaves unequally pinnate, and flowers in axillary or terminal racemes. They are generally possessed of cathartic properties, their leaves or roots being employed. Plugge (*Proc. A. P. A.*, 1897, 560) examined the root of *T. macropoda* and found a poisonous active principle, not identical with cytisine. *Tephrosia virginiana*, Pers., grows in most parts of the United States. It is a foot or two high, with pubescent stems and leaves and handsome terminal flowers. (See Griffith's *Med. Bot.*, 237.) The roots, which are slender, long, and matted, are tonic and aperient, and are said to have been used by the Indians as a vermifuge, given in the form of decoction.

TERPINOL. This is not a simple body, but a mixture of terpenes with variable proportions of an alcohol *terpineol*, $C_{10}H_{17}OH$. It forms a colorless oily substance with a hyacinthine odor produced by boiling terpin with diluted mineral acids. It is insoluble in water, but readily soluble in alcohol and ether, and may be given in pills or capsules in doses of from three to five grains (0·19–0·3 Gm.) four times a day. It is affirmed not to affect the nervous system or the kidneys, but to be a useful expectorant. Dr. Lazarus, of Berlin, administers it in *chronic catarrh* when the bronchial mucous membrane is much irritated, with scanty secretion.

TERRALINE. *Terroline.* A liquid proprietary petroleum product, odorless and tasteless, used internally in emulsions, in the dose of from one to two fluidrachms (3·6–7·3 C.c.).

TESTA PRÆPARATA. *Prepared Oyster-shell. Magistère de Coquilles* (*d'écailles*) *d'Huîtres*, Fr. *Präparirte Austerschalen*, G. "Take of Oyster-shell *a convenient quantity*. Free the Oyster-shell from extraneous matter, wash it with boiling water, and, having reduced it to a fine powder, treat this in the manner directed for Prepared Chalk." *U. S.* Prepared oyster-shell differs from prepared chalk in containing animal matter, which, being very intimately blended with calcium carbonate, is supposed by some physicians to render the preparation more acceptable to a delicate stomach. It is given as an antacid in *diarrhœa*, in the dose of from ten to forty grains (0·648–2·59 Gm.) or more, frequently repeated. A preparation has been introduced into use in this country, under the name of *Castillon's powders*, consisting of sago, salep, and tragacanth, each, in powder, *a drachm*, prepared oyster-shell *a scruple*, and sufficient cochineal to give color to the mixture. A drachm of this is boiled in a pint of milk, and the decoction used *ad libitum* as a diet in *chronic bowel affections.*

TEUCRIUM CHAMÆDRYS. L. *Germander. Chamædrys. Petit Chêne*, Fr. A small European labiate, which has been employed as a mild corroborant in *uterine*, *rheumatic*, *gouty*, and *scrofulous affections*, and *intermittent fevers*. Germander was an ingredient in the *Portland powder*, noted as a remedy in gout. This powder, according to the original prescription, consisted of equal parts of the roots of *Aristolochia rotunda*, L., and *Gentiana lutea*, L., of the tops and leaves of *Teucrium chamædrys*, L., and *Erythræa centaurium* (L.), Pers., and of the leaves of *Ajuga chamæpitys*, Schreb., or *ground pine*. The dose was a drachm every morning before breakfast, for three months, then two scruples for three months, afterwards half a drachm for six months, and finally half a drachm every other day for a year. (Parr.) Two other species of Teucrium have been used in medicine,—*T. marum*, L., *cat thyme*, or *Syrian herb mastich*, indigenous in the south of Europe, and *T. scordium*, L., or *water germander*, growing in the higher latitudes of the same continent. The former is a warm, stimulating, aromatic bitter, and has been recommended in *hysteria*, *amenorrhœa*, and *nervous debility;* the latter has the odor of garlic, and a bitter, somewhat pungent taste, and was formerly highly esteemed as a corroborant in *low forms of disease;* but neither of them is now much employed. *T. marum* is an errhine, and was formerly an ingredient of the *Pulvis Asari Compositus*. The dose of either of the three species is about half a drachm (1·94 Gm.). A plant said to have been used advantageously in *cholera* in the Levant, a specimen of which was sent to Paris, proved to be *Teucrium polium* (L.?). (*Journ. de Pharm.*, xv. 352.) Moorhof (*Pharm. Central.*, 1893, 89) prepared a purified liquid extract from *T. scordium*, and named it *teucrin*, which he recommends in the treatment of fungoid diseases and abscesses.

TFOL. A mineral from Algeria, consisting, according to Lahache, of alkaline earthy silicates, calcium carbonate, silica, alumina, alkaline sulphates, and chlorides. It has been used to form an emulsion with fixed oil and water.

THALICTRUM. It appears probable that many species of this genus (nat. ord. Ranunculaceæ) have active medical or toxic properties. In 1879 Henriot and Doassans asserted that they had separated from the roots of the *Thalictrum macrocarpum*, Gren., a crystalline yellow substance, having very pronounced toxic principles, analogous to those of curare; and subsequently stated (*Bull. Soc. Biol.*, 1880) that this substance really consists of two principles,—an alkaloid, *thalictrine*, obtained in the form of prismatic needles, insoluble in water, soluble in alcohol, forming crystalline salts with acids; and *macrocarpin*, a yellow crystalline body, soluble in water, representing the coloring principle of thalictrum. Subsequently *berberine* was found by Doassans and Mousset in *Thalictrum flavum;* macrocarpin being, according to this authority, very closely allied to berberine, but differing in that its color is not affected by ammonia. Rochebrune (*Toxicol. Africaine*, i.) has found both thalictrine and macrocarpin in the roots of *Thalictrum glaucum*, Desf. Thalictrine he states to be a very active cardiac poison, producing loss of power, convulsive movements, irregularity and depression of the heart's beat, and finally death in some cases in convulsions. According to Rochebrune, thalictrine also exists in the African species, *Thalictrum rhynchocarpum*, Q. Dillon and A. Rich.

THALLIN. *Tetrahydroparaquinanisol* or *Tetrahydroparamethyloxyquinoline.* $C_9H_6H_4N(OCH_3)$. The term anisol is applied to the methyl ether of phenol, and it is therefore methyloxybenzene. Skraup's synthesis of quinoline, C_9H_7N, was effected by heating aniline or amidobenzene with nitrobenzene, glycerin, and sulphuric acid. By taking instead paramidoanisol, paranitroanisol, glycerin, and sulphuric acid, Skraup obtained paraquinanisol, $C_9H_6N(OCH_3)$. This is then treated

with tin and hydrochloric acid, when it takes up four atoms of hydrogen and becomes $C_9H_6H_4N(OCH_3)$. The name thallin was given to this base because of the deep green color produced by ferric chloride and other oxidizing agents. The base thallin is obtained in well-formed rhombic crystals, which fuse at 40° C., and recrystallize on cooling. It shows a neutral reaction and has a characteristic aromatic odor resembling that of coumarin. It is soluble in water, alcohol, and ether.

Thallin Sulphate is a white crystalline powder, which loses its two mols. of water of crystallization at 100° C., and melts at 110° C. It is soluble in five times its weight of cold water and freely soluble in boiling water, soluble in 100 parts of alcohol. Both solutions turn brownish on exposure to air and light. The odor of the sulphate recalls that of anisol. *Thallin Tartrate* is a white crystalline powder, fusing at 155° C., and possessing a coumarin-like odor. It is soluble in ten parts of water and hardly soluble in alcohol. Its aqueous solution has an acid reaction.

Thallin tartrate and sulphate are medically equivalent. They are powerful antipyretics, acting also, when in sufficient dose, as depressants both upon the vaso-motor system and upon the heart; and, according to A. Robin, checking tissue waste in the body, and having a very marked tendency to attack the red blood-corpuscles. These salts have been used in practical medicine, in doses of from four to eight grains (0·259–0·518 Gm.), but are so prone to produce disagreeable symptoms, such as marked cyanosis, vomiting, diarrhœa, albuminuria, etc., that their employment has been abandoned. According to Kreis, in from 4 to 4½ per cent. solution they are active germicides, and the frequent use of urethral injections of the 1 to 2 per cent. solution has been found very useful in *chronic gonorrhœa*. Moncorvo states that thallin is an active hæmostatic.

THALLIUM. (Tl. Atomic weight, 203·7.) This metal, discovered by spectrum analysis, has been found to prevail widely in nature. The credit of its discovery by Crookes in 1861 has been disputed by Lamy. M. Lamy, having experienced, while making chemical investigations in reference to thallium, extreme general lassitude, with pains in the lower extremities, experimented upon the lower animals and found the sulphate to be a violent but very slowly acting poison. He readily recognized the thallium in the tissues of animals which perished with it, the spectroscope revealing a sharply defined green line. (*Journ. de Pharm.*, 1863, 285.) According to Wm. Marmé, small doses of the different preparations of thallium are tolerated for a short time, but the effects are cumulative; after the continued use of the poison the appetite is impaired, intestinal pain is felt, and vomiting occurs, with diarrhœa, hemorrhage, salivation, and emaciation. General debility, embarrassed respiration, weakness of the circulation, disordered muscular action, as tremors and want of co-ordination, are added to the other symptoms; and, when the poisoning becomes general, conjunctivitis, with free secretion of mucus, is a frequent symptom. After death, small effusions of blood and infiltration of the lungs are observed, as are also intense congestion of the bowels, copious pericardial effusion, and ecchymoses on the heart's surface. The poison is eliminated in all the secretions. (See also *Journ. de Pharm.*, 4e sér., x. 263.) It seems to disorganize the blood. There is no known antidote. (*Brit. and For. Medico-Chir. Rev.*, 1868, 254.) According to M. Rabuteau, after death from thallium the muscles are found to have lost their irritability. (*Ed. Med. Journ.*, 1874, 272.) According to Combemale, *thallium acetate* is an efficient remedy in *night-sweats*. A pill containing ten centigrammes should be given at bedtime for not longer than four days in one course.

THANATOL. *Guæthol. Ajacol. Pyro-catechin-mono-ethyl-ether.* $C_6H_4{<}^{OC_2H_5(1)}_{OH(2)}$. An oily liquid, homologous with guaiacol, having similar medical properties.

THAPSIA GARGANICA. L. *Thapsie, Faux fenouil*, Fr. *Thapsie*, G. An umbelliferous plant, growing in Southeastern Europe, and well known to the ancients, who named it from the isle of Thapsos, where it was obtained. Theophrastus speaks of its root as emetic and purgative. After long neglect this plant has obtained a foothold in the French Codex, which recognizes a *Resina thapsiæ* prepared by exhausting the bark of the root with alcohol and evaporating to a soft extract. From this extract the Codex furthur directs that an *Emplastrum thapsiæ* shall be so prepared as to contain 7 per cent. of the resin combined with yellow wax, turpentine, and colophony. The bark of the root and the resin are both objects of commerce. The bark is described by M. Stanislaus Martin as almost always doubly quilled, unless where altogether in small fragments, exteriorly rugose with the epidermis here and there detached in patches larger or smaller, and of a deep brown color, interiorly smooth and whitish, and of a fibrous fracture. The size of the pieces vary, the largest not exceeding twenty-four inches in length and an inch in circumference. At the point where the root is attached to the stem there is often adherent a ligneous fibre about an inch long, and over the whole surface there are found but few radicles. It is said that great care is necessary, in removing the root from the bales, not to be injured by the powder which escapes, and which causes itching and swellings of the face and hands. By submitting thapsia to the successive action of alcohol and ether M. Pressoir obtained two resins. Sulphuric acid colored that soluble in alcohol scarlet, that soluble in ether blue. (*Journ. de Pharm.*, 4e sér., xi. 328.) Canzoneri finds that the ethereal extract is an amber-colored syrupy resin possessing vesicating properties. From it he has obtained two acids, *octoic* or *caprylic* acid, and *thapsic* acid, besides a neutral non-nitrogenous vesicating substance. (See *A. J. P.*, vol. xiv. 325.) M. Cazenave objects to the plaster prepared from the resin, and kept in masses, as it deteriorates by time. He proposes the following method of preparing a plaster extemporaneously when wanted. Dissolve the resin in alcohol, and with the aid of a brush spread it on a suitable recipient, which may be ordinary plaster, waxed taffetas, or simply gummed paper. A single layer is sufficient for the purpose of an active revulsion, but the effect may be increased at pleasure by increasing the number of layers. (*Journ. de Pharm.*, 1868, 29.) The French thapsia plaster is an exceedingly active counter-irritant, producing much inflammation of the skin with an eczematous eruption and intolerable itching, and, if the application be maintained, finally an ulcerated and suppurated surface, which on healing leaves behind it pronounced scars. The therapeutic

action of the plaster is that of a severe counter-irritant.

The resin from the root of the *Thapsia silphia*, St.-Laz., an Algerian plant, which most botanists believe to be a simple variety of the *T. garganica*, L., is, according to Herlaut, more active than that of the official plant. (*Proc. A. P. A.*, xxvi. 250.) Messrs. Heckel and Schlagdenhauffen (*Nouv. Remèdes*, June and July, 1887) find in the root of the *Thapsia villosa*, L., a vesicant resin, which acts more slowly and gently than does that of *T. garganica*.

THERMIN. *Tetrahydro-β-naphthylamine Hydrochloride.* $C_{10}H_7.H_4.NH_2\,HCl$. The tetrahydro addition compound is formed when metallic sodium is caused to act upon the naphthylamine in boiling amyl alcohol solution. The hydrochloride has been brought forward by Prof. Filehne, of Breslau, as a local mydriatic of extraordinary power. It is asserted that in from 1 to 5 per cent. solution it dilates the pupil more widely than does atropine.

THERMODIN. *Acetyl-para-ethoxy-phenyl-urethane.* $C_6H_4(OC_2H_5)N(COCH_3)COOC_2H_5$. A derivative of urethane in the form of a colorless, crystalline powder, fusing at from 86°–88° C., insoluble in water. It is used as an antipyretic in doses of from five to fifteen grains (0·32–0·9 Gm.).

THEVETIA. *Yccotli.* Inhabiting the damp, hot valleys of the Mexican Cordilleras is a large tree belonging to the Apocynaceæ, whose fruits are known by the natives as *huesos ó codos de fraile*, or *friar's elbow bones*, and are used as a topical application in *hemorrhoids*. The tree is the *Thevetia yccotli*. (A. D. C., *Prodromus*, viii. 343.) In the seeds Prof. Alfonso Herrera has found a glucoside, *thevetin*. (*A. J. P.*, 1877, 145.) Closely allied to *T. yccotli* is the *T. neriifolia*, Juss. (De C., *Prodromus*, viii. 343), a tree which probably grows also in Mexico, but has been found by botanists chiefly, if not solely, in the East India Islands, Colombia, Peru, and other parts of South America. De Vrij very many years ago discovered in its seeds a glucoside which was closely studied by Blas. (*Neues Jahrb. f. Pharmacie*, Bd. xxxiv., 1854, 1.) He gave it the name of *thevetin*, and the formula $C_{54}H_{84}O_{24}$, and believed it to be identical with *cerberin*, previously found by Oudemann in *Cerbera odallam* (Ham.), also an apocynaceous plant. Plugge (*Archiv der Pharmacie*, 1893, 10) has made a very thorough study of the cerberin from *Cerbera odallam*, Gaertner, and finds that it is not identical with either tanghinin or thevetin. With the former it is isomeric, showing the same percentage composition, but has different crystalline form and melting points (cerberin 192° C., tanghinin 182° C.). From thevetin it differs not only in composition, but in the nature of the decomposition products. Cerberin, $C_{27}H_{40}O_8$, is decomposed into *cerberetin*, $C_{19}H_{26}O_4$, a citron-yellow amorphous powder melting at 85·5° C., and glucose, while thevetin, $C_{54}H_{84}O_{24}$, is split into *theveresin*, $C_{48}H_{70}O_{17}$, a white powder, and glucose.

Merck (*Jahresbericht für* 1892, 57) has described a glucoside cerberin to which he gives the formula $C_{25}H_{38}O_{13}$. He states that it was obtained from a Mexican plant, probably *Thevetia yccotli*. Whether this glucoside be identical with the thevetin of Blas cannot be definitely stated. Blas found that the thevetin of De Vrij boiled in dilute sulphuric acid splits into glucose and *theveresin*, which has the formula $C_{48}H_{70}O_{17}$. Thevetin occurs in minute crystals, odorless, of a bitter taste, slightly soluble in cold water (twelve parts), freely so in boiling water, dilute and strong alcohol, acetic acid, insoluble in ether. Its most characteristic reaction appears to be its dissolving in concentrated sulphuric acid, with the production of a reddish-brown color, changing to a cherry-red, and after some hours to a violet color. In commerce it occurs as a yellowish-white, amorphous bitter powder, easily soluble in water and alcohol. Theveresin is only slightly soluble in boiling water. These substances are active poisons. A number of cases of poisoning by the seeds of the East Indian thevetia have occurred; the symptoms have been repeated vomiting, a slow, very feeble pulse, delirium, convulsive movements, and coma. The physiological action of the thevetin from *T. neriifolia* has been investigated chiefly by Dr. König. (*Archiv f. Exper. Path. und Pharm.*, Bd. v. 228.)

David Cerna finds that the glucoside of *T. yccotli* (*Phila. Med. Times*, ix. 396) with sulphuric acid affords a clear greenish-yellow solution, gradually passing to brown and brownish violet, and finally becoming a permanent cherry-brown color, which changes on the addition of potassium bicarbonate to an emerald-green; also that it is in moderate doses stimulant both to the circulation and respiration, but finally paralyzes the heart-muscle and the respiratory apparatus; that it causes cerebral convulsions and spinal paralysis, abolishing sensation and reflex activity before voluntary movement by an influence upon the sensory nerves or spinal tract. Zotos N. Zotos (*Inaug. Diss.*, Dorpat, 1892) states that *cerberin* belongs physiologically to the digitalin group.

THIALDINE. $C_6H_{13}NS_2$. This substance, obtained when hydrogen sulphide acts upon aldehyde-ammonia in aqueous solution, forms crystals melting at 43° C., which are but slightly soluble in water, more easily in alcohol. It has been investigated by Prof. Lusini, who found it a general paralyzing agent, acting powerfully upon the heart, which it arrests in diastole; whilst *carbothialdine*, $C_5H_{10}N_2S_2$, formed by the action of carbon disulphide in alcoholic solution upon aldehyde-ammonia, acts as a tetanizing agent and does not affect the heart. (See *Nouv. Rem.*, Nov. 1890.)

THILANIN. This substance is said to be made by the action of sulphur upon lanolin, and contains about 3 per cent. of the active ingredient. It is of the consistence of lanolin, of a brownish color and peculiar odor. It is said not to be irritating, and has been used without dilution with asserted excellent results in *chronic eczema* and other *skin eruptions* in which sulphur has been employed.

THIOCOL. *Potassium Guaiacol Sulphonate.* $CH_3\begin{cases}OH\\OCH_3\\SO_3K\end{cases}$. This is a fine white powder, having a taste at first bitter and afterwards sweetish; readily soluble in water; containing about 60 per cent. of guaiacol. It is affirmed to be not at all irritant to mucous membranes, and has been recommended especially by C. Schwarz (*Klin. Therap. Wochen.*, 1898) in the treatment of *tuberculosis*, *chronic bronchitis*, and *intestinal catarrh*. Forty-five grains (2·8 Gm.) of it may be given three times a day, increased to two hundred grains (13 Gm.) a day.

THIOFORM. This is a basic bismuth salt of dithiosalicylic acid; it is a yellow, insoluble, inodor-

ous powder, non-poisonous, and used as a substitute for iodoform.

THIOL. This is a thin, dark brown, neutral liquid, with an odor somewhat like that of Russia leather; having a specific gravity of from 1·082 to 1·089; forming clear solutions with water, which froth when shaken and are not precipitated by strong alcohol; it is also feebly soluble in glycerin. On evaporation, liquid thiol yields about 40 per cent. of dried thiol. It is prepared from paraffin oils of from 0·89 to 0·90 sp. gr., which are treated with sulphur at high temperatures. The unsaturated hydrocarbons (olefins, etc.) are alone attacked, and these are then extracted by suitable solvents from the saturated hydrocarbons. They are then acted upon by concentrated sulphuric acid at low temperatures, and the thiol separated out by the addition of ice. It may then be evaporated *in vacuo* to either *thiolum liquidum* or *thiolum siccum*. It is asserted that thiol possesses the remedial properties of ichthyol, and is superior in being odorless. It has been used in *eczema*, *syphilitic* and other *superficial ulcerations*, *acute infiltration of joints*, *sprains*, *contusions*, *erysipelas*, etc., precisely as has ichthyol The liquid is used in the form of a solution or ointment; the dried thiol is sometimes employed as a powder. In *rheumatism*, thiol has been given internally in doses of from five to ten drops, or the dried preparation in doses of from one to two grains. (0·06–0·13 Gm.).

THIOLINIC ACID. This is described as a darkish green extract-like mass, having the odor of mustard; it has been called *sulphurated linseed oil*; it is insoluble in water; soluble in alcohol. Its alkaline combinations, especially with the sodium salts, have been recommended as substitutes for thiol and ichthyol.

THIOPHENE (C_4H_4S) was recognized by Victor Meyer in 1883 as being an invariable accompaniment of benzene as produced from coal tar, and because of the similarity of properties adhering very closely to it through all reactions. It can be separated by shaking up the benzene with one-tenth of its bulk of concentrated sulphuric acid until the addition of a little isatine no longer produces a blue color (indophenin reaction). Thiophene is a colorless, mobile oil, of faint odor, and boils at 84° C. Just as benzene is accompanied in coal tar by toluene, xylene, and higher homologues, so thiophene is accompanied by *thiotolene* (*methyl-thiophene*), $C_4H_3S.CH_3$, and *thioxene* (*dimethyl-thiophene*), $C_4H_2S.(CH_3)_2$. Thiophene and its homologues yield a large number of brilliant dye-colors analogous to those derived from benzene. It was first physiologically tested by A. Heffter (*Archiv f. d. Gesammte Physiol.*, 39, 420), who found that it appeared in the urine, and lessened the elimination of sulphuric acid in the urine. Dr. E. Spiegler (*Therap. Monat.*, Feb. 1892) has employed in *skin diseases*—1, the *sodium thiophene sulphonate*, $C_4H_3S—NaSO_3$; 2, the *thiophenediiodide*, $C_4H_2I_2S$. The first of these compounds is a white crystalline powder, containing 33 per cent. of sulphur, having a feeble, disagreeable odor. It was found in from 5 to 10 per cent. ointment to act very well in *prurigo* with *eczema*. Thiophenediiodide crystallizes in beautiful tables melting at 40·5° C., having a characteristic, not disagreeable smell; insoluble in water, but very feebly soluble in ether, chloroform, and warm alcohol; soluble with difficulty in cold alcohol; containing 75·5 per cent. of iodine and 9 5 per cent. of sulphur. It was found to be antiseptic, and was suggested as a substitute for iodoform.

THIOSAPOL. Soap containing from 5 to 10 per cent. of sulphur in combination, used in treating skin diseases.

THIOSINAMIN. *Allyl-sulpho-urea. Allyl-sulphocarbamide.* $CS\begin{cases}NH_2\\NH(C_3H_5)\end{cases}$. This occurs in colorless prisms, melting at 74° C., moderately soluble in water, alcohol, and ether, having a faint garlic odor and a bitter taste. It is prepared by warming mustard oil with ammonia containing traces of ammonium rhodanate. It was originally proposed for use in medicine by Dr. H. von Hebra (*Internat. Klin. Rundschau*, Sept. 1892), who affirms that when it is injected subcutaneously it produces in *lupus* and other local *tuberculous diseases* a reaction, attended by absorption of exudate, often by increased diuresis and clearing up of old *corneal opacities*. He asserts that it acts like tuberculin. Clinical experience has shown, however, that thiosinamin is of very little or no value in the treatment of tuberculosis. On the other hand, it is much used, especially in Vienna, for the softening of *keloid growths*, *scar-tissues*, and other forms of adventitious low-grade tissues and post-inflammatory deposits. Hebra and Richter report cures of *corneal opacities*, and *urethral strictures* are said to be greatly benefited by the drug, so that it is possible by preparatory treatment to convert the difficult and dangerous operation of dilatation into a simple one. (*New York Med. Journ.*, Nov. 1897.) According to K. Lange, thiosinamin is toxic in overdose. Hebra used the 15 per cent. alcoholic solution injected into the back in such quantity that the patient receives from four and one-half to seven grains (0·3–0·45 Gm.) of the thiosinamin, repeating the injection every third or fourth day. A solution may be made by dissolving 10 parts of the drug in 100 parts of a sterile mixture of water and glycerin, which keeps well and is non-irritant. As a full dose, twelve or fifteen minims (0·74–0·92 C.c.) are injected into a muscle every third day.

THIURET. $C_3H_7N_3S_2$. A sulphurated compound made by the oxidation of phenyl-dithiobiuret; it is a bulky, inodorous, crystalline powder, insoluble in water, soluble in alcohol and ether, easily decomposed by alkaline solutions with liberation of sulphur. It is used as a substitute for iodoform.

THUJA. *U. S.* 1880. *Arbor Vitæ. Thuja occidentalis*, L. (nat. ord. Coniferæ), is specifically characterized by the peculiarities of the leaves, the pointless cone-scales, and the broad wings extending all around the seeds. It attains a height of fifty feet and a diameter of three feet, but is usually much smaller, and grows in swampy grounds from Pennsylvania northward and westward, often forming extensive "cedar swamps." In Canada and the extreme northern parts of the United States it is commonly called *white cedar*, a name sometimes applied to the *Cupressus thyoides*, L. (now *Chamæcyparis thyoides* (L.), B. S. P.), which latter is more properly called *Southern white cedar*. The wood is reddish, soft, fine-grained, and very durable. The leaves, or small twigs invested with the leaves, are the parts used. They have an agreeable balsamic odor, especially when rubbed, and a strong, balsamic, camphoraceous, bitter taste, and are flattish, two-edged, with the scale-like leaves appressed and closely imbricate in four rows, rhombic-ovate, ob-

tusely pointed, with a roundish gland upon the back. A. Kawalier, of Vienna, found in them volatile oil, a bitter principle called *pinipicrin*, $C_{22}H_{36}O_{11}$, found also in *Pinus sylvestris*, sugar, gelatinous matter, a variety of wax, resin, and tannic acid (see *Chem. Gaz.*, Feb. 1, 1855, 45); also a peculiar crystallizable coloring principle, *thujin*, to which he gives the formula $C_{20}H_{22}O_{12}$. It is of a citron-yellow color and an astringent taste, soluble in alcohol, inflammable, and when its alcoholic solution is heated with dilute hydrochloric or sulphuric acid it splits up into glucose and *thujigenin*, $C_{20}H_{22}O_{12} + H_2O = C_6H_{12}O_6 + C_{14}H_{12}O_7$, and by continuing the reaction another molecule of water is taken up and *thujetin*, $C_{14}H_{14}O_8$, is formed. Thujetin is possibly identical with quercetin. When thujin is heated with barium hydrate, instead of thujetin is obtained another product, *thujetic acid*, $C_{28}H_{22}O_{13}$. The same chemist determined that the tannic acid of this plant is identical with *pinitannic acid*, which he had previously obtained from the leaves of *Pinus sylvestris*. (See, for details, *Chem. Gaz.*, Nos. 392, 393, 1859.) According to Hübschmann, the leaves and twigs of *Thuja occidentalis* yield also 1 per cent. of an essential oil of sharp, camphor-like taste, sp. gr. 0·925, boiling point from 190°–206° C., and easily soluble in alcohol. According to *Schimmel's Report* (April, 1897), thuja oil contains *pinene*, *fenchone*, *thujone*, and probably *cervone*.

In the form of decoction, thuja has been used in *intermittent fever*, and, according to Schoepf, in *coughs*, *fevers*, *scurvy*, and *rheumatism*, and as an emmenagogue. Made into an ointment with lard or other animal fat, the leaves are said to form a useful local application in rheumatic complaints. A yellowish-green volatile oil, which may be obtained from the leaves by distillation, has been used with success in worms. The dose of a saturated tincture or fluid extract is a fluidrachm (3·7 C.c.) from three to six times a day.

THYMACETIN.

$C_6H_2(CH_3)C_3H_7\left\{\begin{matrix}OC_2H_5\\NH(C_2H_3O)\end{matrix}\right.$. This is a white crystalline powder, slightly soluble in water, having the same chemical relation to thymol that phenacetin has to phenol. It should show, therefore, the general characters of phenacetin with the antiseptic character of thymol. According to Jolly (*Cent. f. die Gesammte Therap.*, Feb. 1892), it is a very valuable analgesic, and has also hypnotic influences. Dose, from three to fifteen grains (0·19–0·9 Gm), best given in capsules.

THYMUS GLAND. The close connection which exists between the development of the body and the thymus gland would suggest the use of the extract in *rickets* and other diseases which occur especially during the developmental stage of life, and are accompanied by marked failure of nutrition. We know, however, of no studies made upon the subject. Without any apparent guiding principle the extract of the thymus has been used to a considerable extent in the treatment of *exophthalmic goitre*. The results appear to warrant the conclusion that the thymus gland possesses no specific action in Graves's disease. That the thymus body has some activity seems to be indicated by the experiments of Svehla, who found that its intravenous injection produces a marked fall of blood-pressure which he believes to be the outcome of vaso-motor paralysis, and that large doses cause dyspnœa and collapse, ending in death. Dose of extract, from three to five grains (0·19–0·3 Gm.) in capsules.

TILIACIN. This is a glucoside which has been found in the leaves of the linden-tree and in the *Cirsium arvense*. (*A. J. P.*, 1890.)

TIMBO. This name is said to be applied in Brazil to various sapindaceous plants, used as fish-poisons. Among these is the *Paullinia pinnata*, L. (now *Serjania curassavica*, Radlk.), in which M. Stanislaus Martin (*Bull Gén. Thérap.*, xcii.) has found an alkaloid, *timbonine*; F. Pfaff has obtained from a timbo of unknown origin two alkaloids, *timboin* and *anhydrotimboin*, also an oily compound, *timbol*. (*A. J. P.*, Nov. 1891.)

TIN. (Sn. At. wt. 118·8.) *Stannum. Etain*, Fr. *Zinn*, G. This was recognized in the old Ed. and Dub. Pharmacopœias, and in the U. S. of 1850; but is no longer official. It has, however, too long ranked among recognized remedies to be passed without notice. Tin is one of the metals which have been known from the earliest ages. It exists generally as an oxide (*tin stone* and *wood tin*), rarely as a sulphide (*tin pyrites*), and is by no means generally diffused. It is found in England, Spain, Germany, Bohemia, and Hungary, in Europe, and sparingly in some parts of the United States; in the island of Banca and the Peninsula of Malacca in Asia; in Chili; and at Durango in Mexico. The mines of Asia furnish the purest tin. The metal is extracted from the native oxide. When this occurs in its purest state, in detached roundish grains, called *stream tin*, the reduction is effected by heating with charcoal. When the common oxide, called *mine tin*, is reduced, it requires to be freed, by pounding and washing, from the adhering gangue, after which it is roasted to drive off sulphur, arsenic, and antimony, and finally reduced in furnaces by means of stone coal. The metal, as thus obtained, is called *block tin*, and is not pure. The purest kind of tin known in commerce is called *grain tin*. The importations of block tin into the United States for the year 1897 amounted to 50,460,123 lbs., valued at $6,505,852, while the tin and terne plate, which in 1893 amounted to over 628,000,000 lbs., had diminished in 1897 to 230,073,683 lbs., valued at $5,344,638.

Tin is a malleable, rather soft metal, of a silver-white color. It may be beaten out into thin leaves, called *tin foil*. It undergoes a superficial tarnish in the air. Its taste is slight, and when rubbed it exhales a peculiar smell. Its ductility and tenacity are small; when bent to and fro, it emits a crackling noise, which is characteristic. Its sp. gr. is 7·29, melting point 235° C. (455° F.), and it volatilizes at a white heat. It forms two oxides. The *stannous oxide*, SnO, or *protoxide*, is of a grayish-black color. When perfectly pure it has, according to Roth, a red color. *Stannic oxide*, SnO_2, or *dioxide*, forms two hydrates, both being acids,—*stannic acid*, SnO_2,H_2O, and *metastannic acid*, $Sn_5O_{10},5H_2O$, or $(H_2SnO_3)_5$.

The tin of commerce is often impure, being contaminated with other metals, introduced by fraud or present in consequence of the mode of extraction from the ore. A high specific gravity is an indication of impurity. When its color has a bluish or grayish cast, the presence of copper, lead, iron, or antimony may be suspected. Arsenic renders it whiter, but at the same time harder; and lead, copper, and iron cause it to become brittle. Pure tin

is converted by nitric acid into a white powder (*metastannic acid*), without being dissolved. Boiled with hydrochloric acid, it forms a solution which gives a white precipitate with potassium ferrocyanide. A blue precipitate with this test indicates iron, a brown one copper, and a violet-blue one both iron and copper. If lead be present, a precipitate will be produced by magnesium sulphate. The Malacca and Banca tin and the English grain tin are the purest kinds found in commerce. Banca tin, from analyses by Mulder, appears to be particularly pure, containing only one-twenty-fifth of one per cent. of foreign metals. Block tin and the metal obtained from Germany are always of inferior quality.

Tin enters into the composition of bronze, bell-metal, pewter, and plumber's solder. It is used also in making tin-plate, which is sheet-iron coated with tin, in making tin amalgam for silvering looking-glasses, and in forming the *solution of bichloride of tin* (stannous chloride), a combination essential for the dyer's use. It is employed in fabricating various vessels and instruments useful in domestic economy and the arts. Being unaffected by weak acids, it forms a good material for vessels intended for boiling operations in pharmacy. A *false tin foil* is considerably used at present, made by coating lead with tin, and then rolling it out into thin sheets. As tin foil is employed for enclosing medicinal powders and perishable articles of food and medicine, care should be taken not to use this substituted preparation.

STANNI PULVIS. *Powder of Tin.* For directions for making, see 16th ed. *U. S. D.* Powder of tin was used as a mechanical anthelmintic, but has very properly gone out of vogue. The dose is half an ounce, mixed with molasses, given for several successive mornings, and then followed by a brisk cathartic purge. In the *Journ. de Pharm.*, 4e sér., xix. 78, is reported a death believed to have been caused by tin. Dr. Patengo (*Archiv f. Exper. Path. u. Pharm.*, xvii., 1886) confirms the old statement of Orfila that the metal is of no therapeutic value. Three-fourths of a grain of the chloride intravenously injected into the dog suffice to cause trembling, Cheyne-Stokes respiration, opisthotonos, and death. Stannous chloride, or chloride of tin, is a violent irritant and mild caustic. Chemically pure tin, given internally, is probably not absorbed. (See 16th ed. *U. S. D.*)

TODDALIA. *Lopez Root.* The bark of the root of the East Indian plant *T. aculeata* has been used as a tonic and stimulant in fevers and dysentery. (*Pharm. Rev.* 1896, 274.)

TOLYPYRINE. *Tolyantipyrin, Para-tolyl-dimethyl-pyrazolon.* $C_6H_4CH_3N<\begin{matrix}CO.CH\\N.CH_3.C.CH_3\end{matrix}$.

This compound occurs in colorless crystals soluble in water and alcohol, insoluble in ether, and is used like antipyrin as an antipyretic in doses of from eight to thirty grains (0·5–1·9 Gm.).

TONGA. Tonga is a composition of unknown barks compounded by the natives of the Feejee Islands for medicinal purposes. The plants from which this remedy is derived are believed to be *Premna taitensis*, Schan. (nat. ord. Verbenaceæ), and *Rhaphidophora vitiensis*, Schott. (now *Epipremnum mirabile*, Schott.) (nat. ord. Aroideæ). (*A. J. P.*, 1881, 439.) It was introduced to the notice of the medical profession by Sydney Ringer and Wm. Murrell, of London, as a remedy for *neuralgia*. (*Lancet*, ii., 1880.) The natives are said to steep the bundle as prepared by them for twenty minutes in half a tumblerful of cold water, and then, squeezing it dry, drink the infusion, and preserve the bundle in a dry place for further use. A fluid extract has been put upon the market, and evidence of its value brought forward, but we have known a fluidrachm of this extract given every two hours for two days without obvious effect; the dose usually recommended is half a fluidrachm (1·84 C.c.).

TONKA BEAN. *Fève Tonka*, Fr. *Tonkabohnen*, G. The seed of *Dipteryx odorata* of Willd., the *Coumarouna odorata* of Aublet, a large tree growing in Guiana. The fruit is an oblong-ovate pod, enclosing a single seed, from an inch to an inch and a half long, from two to four lines broad, usually somewhat compressed, with a dark brown, wrinkled, shining, thin, and brittle skin, and a light brown oily kernel. The seed has a strong, agreeable, aromatic odor, and a bitterish, aromatic taste. Its active constituent is a crystallizable, odorous substance, called *coumarin* or *cumarin*, $C_9H_6O_2$, by Guibourt. It is the anhydride of *coumaric acid*, $C_9H_8O_3$. It is capable of sublimation; but, to obtain it in crystals in this way, a low temperature is necessary. (Waddington, *P. J. Tr.*, 1868, 410.) This substance is sometimes found in a crystalline state, between the two lobes of the kernel. Coumarin appears to be a widely spread substance which has been found in many species of plants, notably in species of *Melilotus* (nat. ord. Leguminosæ) and *Liatris odoratissima*, Willd. (now *Trilisia odoratissima* (Walt.), Cass.) (nat. ord. Compositæ), a plant sometimes used to protect woollens from moths. (*A. J. P.*, 1859, 556; also 1899, 133; see also *Chem. Gaz.*, 1852; *Druggist's Circular*, Nov. 1887.) Dr. Gössmann obtains coumarin in the following manner. The beans, cut finely, are heated for a long time with an equal bulk of alcohol of 0·863, nearly to boiling; and, the tincture being decanted, the residue is treated in the same manner. The tinctures are mixed, the alcohol distilled off until turbidness appears, when four times the bulk of water is added, which precipitates coumarin and fatty matter. The precipitate is then heated to boiling, and the liquid passed through a moistened filter. The fatty matter remains on the filter, and the hot solution which passes deposits the coumarin on cooling. More may be obtained by concentrating the liquid, and may be purified by animal charcoal. One pound of the beans yielded 108 grains of coumarin. (*Ibid.*, 1856, 211.) Coumarin has been prepared synthetically by heating salicylic aldehyde with sodium acetate and acetic anhydride, whereby acetocoumaric acid is formed, which decomposes further into acetic acid and coumarin. It has also been obtained by the action of phenol upon malic acid. The tonka bean is used to flavor snuff, being either mixed with it in the state of powder or put entire into the snuff-box. Coumarin adulterated with acetanilid has been found in the market. (*Schimmel's Report*, 1893, 67.) Prof. Köhler (*Centralb. f. Med. Wissensch.*, 1875, 869, 881) finds that coumarin is a decided narcotic, and is at first stimulant, afterwards paralyzant to the heart. The fluid extract of the bean has been used with asserted advantage in *whooping-cough*, in doses equivalent to from five to eight grains (0·3–0·5 Gm.) for children five years old. (*A. J. P.*, 1869, 27.)

TORMENTILLA. *Rhizoma Tormentillæ*, P.G. *Tormentille*, Fr. *Tormentillwurzel*, G. *Tormentilla*, It. *Tormentila*, Sp. Various species of the rosaceous genus Potentilla have been employed in medicine. (See *A. J. P.*, 1875, 109.) It is asserted (*Ibid.*) that our common *P. canadensis*, L., is a valuable sudorific and diuretic.

Potentilla tormentilla. Neck., also Schrank. *Tormentilla erecta.* Linn. *T. officinalis.* Curt. The tormentil, or *septfoil*, is a small perennial plant of Europe, which was formerly in the Secondary List of the U. S. Pharmacopœia. All parts of the plant are astringent, especially the root, which is the part employed. The root of tormentil is cylindrical or roundish, rather larger above than at the lower extremity, an inch or two in length, about as thick as the finger, knotty, sometimes contorted, brown or blackish externally, and reddish within. It has a slight aromatic odor and a very astringent taste. Tannin is an abundant constituent. There is also a red coloring principle, soluble in alcohol, but insoluble in water. Besides these ingredients Meissner found resin, cerin, myricin, gummy extractive, gum, extractive, lignin, water, and a trace of volatile oil. Tormentil has since been chemically examined by Rembold, who obtained tormentilla red by boiling the tannin of the root (*tormentil-tannic acid*, $C_{26}H_{22}O_{11}$) with sulphuric acid. It has the same composition as rhatany red, and yields the same products of decomposition when fused with caustic potash. He also obtained *kinovic acid*, $C_{24}H_{38}O_4$, from the root by boiling it with milk of lime, adding hydrochloric acid to the decoction, boiling the precipitate with solution of baryta, decomposing again by hydrochloric acid, dissolving the precipitate in alcohol, decolorizing with animal charcoal, filtering, concentrating, and crystallizing. Small quantities of *ellagic acid*, $C_{14}H_6O_8$, were also noted by him. (*A. J. P.*, 1868, 311; from *Ann. der Chem. und Pharm.*, cxliv. 5.) The root is said to be used for tanning leather in the Orkneys and Western Islands of Scotland, and for staining leather red by the Laplanders. Tormentil is a simple and powerful astringent, applicable to all cases of disease in which this class of medicines is indicated. It may be given in substance, decoction, or extract. The dose of the powder is from thirty grains to a drachm (1·94–3·8 Gm.).

TRAGOPONIC ACID. This was found by Messrs. Rademaker and Fisher in the seeds of the *Tragopogon porrifolius.* (Nat. ord. Compositæ.) (See *Nat. Drug.*, July 23, 1886, 47.)

TRAUMATOL. *Iodocresine. Iodocresol.* $C_6H_3,I,(CH_3)OH$. This occurs as a purplish-red or yellow powder; it is obtained by acting on cresol with iodine, and is used as a substitute for iodoform.

TRIBROMALLYL. *Tribromhydrinum.* This is a colorless liquid, having a specific gravity of 2·436, freely soluble in ether. It has been recommended by De Fleury for *hysteria*, *asthma*, and similar nervous affections, in the dose of five drops in capsules from two to four times a day.

TRIBROMPHENOL. $C_6H_2Br_3.OH$. Tribromphenol is prepared by shaking a solution of carbolic acid with bromine water. It occurs in the form of soft, white, colorless needles, melting at 95° C., and subliming undecomposed at a higher temperature. It is soluble in alcohol, ether, and chloroform, and soluble with difficulty in glycerin, carbolic acid, water, and weak alcohol. In caustic alkaline solutions it is readily soluble, and from them it is separated unaltered by acids.

Tribromphenol has been strongly recommended by Dr. Grimm for use in *antiseptic surgery.* He finds that a gauze containing a 2 per cent. solution of the compound, when saturated with blood serum or urine, will remain perfectly odorless for fourteen days, and that a half per cent. solution of it will kill the bacteria of putrescence in an hour.

TRIBROMPHENOL-BISMUTH. *Xeroform.* $(C_6H_2Br_3O)_2BiOH + Bi_2O_3$. This is a yellowish-green, insoluble, almost odorless and tasteless powder, which, according to its manufacturer, is a chemical combination of equal amounts of bismuth and tribromphenol, containing about 50 per cent. of bismuth oxide. It has been especially recommended by Prof. Hueppe (*Berliner Klin. Wochensch.*, 1893) as a specific in *cholera*, and has been used as an intestinal antiseptic in acute and chronic *enteritis* and in various functional and organic diseases of the alimentary canal. The dose is from eight to fifteen grains (0·5–0·9 Gm.).

Xeroform has also been recommended by E. Heuss (*Therap. Monatssh.*, April, 1896) as a local antiseptic remedy for surgical use, especially valuable in the treatment of *burns*, *infected wounds*, *ulcers*, and other conditions for which iodoform is commonly employed. It does not alter under the influence of light; and since it is not decomposed by a temperature of 120° C. (255° F.), can be readily sterilized

TRIBROMSALOL. *Cardol.* ($C_6H_4(OH)COO.C_6H_2Br_3$.) A substance made by the action of bromine in excess on salol has been proposed by Dr. Joseph Rosenberg under the name of tribromsalol, with the statement that it is a markedly calmative remedy, useful for the purpose of allaying *gastric uneasiness*, *cramps*, etc. (*Pharm. Centralh.*, xxxviii.) Dose, from eight to thirty grains (0·5–1·9 Gm.).

TRIGONELLA FŒNUM-GRÆCUM. L. *Fenugreek. Semen Fœnugræci*, P. G. A European annual leguminous plant cultivated in France and Germany for its seeds. These are oblong-cylindrical, somewhat compressed, obliquely truncated at each extremity, one or two lines in length, brownish yellow externally, yellow internally, and marked with an oblique furrow running half their length. They have a strong peculiar odor, and an oily, bitterish, farinaceous taste, and contain fixed and volatile oils, mucilage, bitter extractive, and a yellow coloring substance. E. Jahns (*Ber.*, xviii., 2518–2523) has obtained *choline*, $C_5H_{15}NO_2$, and *trigonelline*, $C_7H_7NO_2$. The yield of the former was 0·05 per cent., and of the latter 0·13 per cent. Trigonelline is isomeric and probably identical with pyridine-betaine. By heating trigonelline with concentrated caustic potash, a distillate is obtained which appears to contain pyridine. An ounce of the seeds, boiled in a pint of water, renders it thick and slimy. They yield the whole of their odor and taste to alcohol. On the continent of Europe they are employed in the preparation of emollient cataplasms, enemata, ointments, and plasters. They are never used internally.

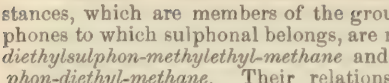
TRILLIUM. *Beth-root. Birth-root. Wake-robin. Trillium*, Fr., G. The indigenous species, *T. erectum*, L., is said to have been employed by the aborigines, and also used by the early settlers; it still has some vogue under the name of *beth-root* as an astringent and tonic expectorant; also in *hemor-*

rhages and to hasten *parturition*, and as a local irritant in *skin diseases*. Dose of powdered root, a drachm (3·88 Gm.) three times a day. Mr. E. S. Wayne found in it a substance supposed to be saponin. It is said also to contain volatile oil and tannic acid. Mr. D. J. Prendergast believes that the *Trillium erectum*, L., contains a glucoside similar to convallamarin. (*Amer. Drug.*, Nov. 1887.) For details, see *U. S. D.*, 16th ed. Vivian I. Reid (*A. J. P.*, 1892, 67) found a small quantity of fixed oil, saponin to the extent of 4·86 per cent., and an acid crystalline principle which is colored purplish brown by sulphuric acid, and light green with sulphuric acid and potassium bichromate.

TRIMETHYLAMINE. *Propylamine. Secaline. Triméthylamine*, Fr. *Trimethylamin*, G. Wertheim in 1850 prepared from narcotine a substance having the formula C_3H_9N, and gave it the name *metacetamine*. In the same year Anderson prepared from codeine, and Hofmann from methyl, substances having the same formula, giving them respectively the names of propylamine and trimethylamine. Other chemists have obtained similarly constituted principles from cod-liver oil, ergot, herring-pickle, putrid calf's blood, codeine, etc., and have even found them in saline combination in the flowers of *Cratægus oxyacantha*, *Sorbus aucuparia*, and one or more species of Chenopodium. Under the name of propylamine some of these principles were introduced into medicine by Dr. Awenarius, of St. Petersburg, and met for a time with considerable favor; so that several processes for preparing propylamine were published before the 13th edition of the *U. S. Dispensatory*. Since that time it has been very clearly shown that these various substances, although containing the same number of atoms, have them differently arranged, are consequently possessed of diverse properties, and are hence only *isomeric*. The material obtained from herring-pickle and other sources and sold as propylamine is indeed not propylamine at all, but a more or less impure solution of trimethylamine; it is, in truth, doubtful whether propylamine has ever been procured from a natural source or made in any other way than by treating propyl iodide with ammonia. Both principles are derived ammonias or *amines*, but propylamine is a primary compound ammonia (monamine), and trimethylamine is a tertiary compound ammonia (triamine). In the first body the nitrogen is combined with two atoms of hydrogen and one propyl group, C_3H_7, in the second with three methyl groups, $(CH_3)_3$.

Propyl, $\left.\begin{matrix} C_3H_7 \\ H \\ H \end{matrix}\right\} N = C_3H_9N$, Propylamine.

Methyl, $\left.\begin{matrix} CH_3 \\ CH_3 \\ CH_3 \end{matrix}\right\} N = C_3H_9N$, Trimethylamine.



The physical differences are very marked. Thus, propylamine boils at 49° C. (120·2° F.), trimethylamine at 9·3° C. (48·7° F.). The commercial propylamine contains other ammonia compounds besides trimethylamine, the latter substance indeed being sometimes present in very small quantity. Trimethylamine is made on a large scale at present by the destructive distillation of the "vinasses," or residues of beet-root molasses. For other processes, see *U. S. D.*, 16th ed., p. 1944.

Brieger has shown that choline, neuridine, and trimethylamine are among the early products of albuminoid decomposition in the human cadaver, and are then followed by other and more poisonous bodies of the ptomaine class.

The best form of trimethylamine for use is probably the hydrochlorate, which may be prepared in a state of purity as a very deliquescent salt, crystallizing in long needles. To form the chloride naturally the distillatory products in M. Perret's process may be received into hydrochloric acid and separated from any ammonium chloride by means of absolute alcohol. *Commercial propylamine—i.e.*, impure solution of trimethylamine—is a colorless transparent liquid, of a characteristic odor, usually attended by some pungency, which may possibly be ascribed to the ammonia frequently mixed with it. It is soluble in water and alcohol, has a strong alkaline reaction, and forms crystallizable salts with the acids. If the end of a glass rod, previously dipped into hydrochloric acid, be held over the open mouth of a vial containing it, a white cloud of the chloride will be seen, as in the case of ammonia. *Pure propylamine* is said to be a perfectly clear, strongly refractive fluid, with the odor of ammonia; a boiling point of 49° C. (120·2° F.); a sp. gr. (at 20° C. (67° F.)) of 0·7186; inflammable; miscible with water. With hydrochloric acid it makes a deliquescent salt, soluble in alcohol, forming with platinum chloride a double salt, which crystallizes in large, dark, golden-yellow clino-rhombic plates, somewhat soluble in hot water and alcohol. *Pure trimethylamine* is a gas at ordinary temperatures.

Locally applied, trimethylamine acts as a powerful irritant or, if in sufficient concentration, even as a mild caustic. According to M. Laborde, in its physiological action it resembles the ammonium chloride or carbonate, though differing in not causing convulsions in animals fatally poisoned with it. (*Med. Times and Gazette*, 1874, 241.) The chloride was found to act in the same way as the trimethylamine, but to be scarcely more than half as powerful. Drs. Combemale and Brunelle have found that the drug is a powerful stimulant to the salivary gland. Given to man, trimethylamine acts chiefly as a violent gastro-intestinal irritant, the dose of half a drachm of the commercial article, even if freely diluted, usually producing distinct effects upon the stomach and the intestines. It has been found to act as a depressant to the circulation, but M. Laborde affirms that unless given in such dose as to produce serious results from its local action, it increases both in man and animals the arterial pressure. In 1854 it was brought forward by Dr. Awenarius, of St. Petersburg, Russia, as a specific in *rheumatism*, and by other Continental physicians some confirmation of the original statements was afforded. Extensive trial made with the remedy in Philadelphia and elsewhere this side of the Atlantic soon led to its abandonment, and at present the remedy has passed entirely out of vogue. Awenarius gave a mixture of twenty-five drops of propylamine with six fluidounces of distilled water, flavored if necessary with sugar and oil of peppermint, and gave a tablespoonful every three hours, taking care that the drug was pure and freshly prepared. (*Ann. de Thérap.*, 1859.) In France, where the chloride was preferred, the following was a favorite formula. Trimethylamine chloride ten grammes, tincture of orange-peel twenty-eight grammes, syrup nine hundred and seventy grammes. A tablespoonful contains about three and one-half grains. The dose of trimethylamine chloride is from seven to fifteen grains (0·454–0·972 Gm.).

TRIONAL. TETRONAL. These two substances, which are members of the group of disulphones to which sulphonal belongs, are respectively *diethylsulphon-methylethyl-methane* and *diethylsulphon-diethyl-methane.* Their relationship to sulphonal (diethylsulphon-dimethyl-methane) will be readily seen by a comparison of formulas.

Sulphonal. Trional. Tetronal.

Baumann and Kast, who first introduced the use of these drugs, affirmed that tetronal is more powerful as an *hypnotic* than is trional (*Zeits. Physiol. Chem.*, 1887); but tetronal has failed to come into use, whilst trional is probably the most used of modern hypnotics, much quicker and more certain in its action than is sulphonal; usually producing sleep not to be distinguished from that which is normal, and only in rare cases causing weakness, giddiness, or other disagreeable after-effects. No death, so far as we know, has been reported as produced by one administration, although one hundred and twenty grains have been taken at a single dose. When taken in overdoses it produces lassitude, giddiness, tinnitus aurium, vomiting, anorexia, obstinate constipation, uncertain gait, ataxia, tremors, lessened secretion of urine, sometimes strangury, and hæmatoporphyrinuria. Even the therapeutic dose has a tendency to cause excessive acidity of the urine. According to Fontoynont, a peculiar empyreumatic odor of the urine is pathognomonic. Chronic poisoning has occurred only rarely. Schultze (*Deutsch. Med. Wochensch.*, 1894) has reported one case in which six drachms of trional were given within four or five weeks. The patient became very feeble, the urine deepened from dark red to almost a black color, and death occurred. In a case recorded in *L'Abeille Médicale*, Feb. 1897, after the ingestion of twenty-one drachms in twenty-six days there was profound ataxia, with aphasic manifestations and great general intellectual and physical feebleness. The dose of either drug is from fifteen to thirty grains (0·972–1·94 Gm.), best administered in milk, just before retiring, as their effect is prompt. It is affirmed that no evil effects follow the prolonged use of these drugs.

TRIOSTEUM PERFOLIATUM. L. *Horse Gentian. Bastard Ipecac. Tinker's-weed. Fever-root. Fever-wort. Wild Ipecac. Racine de Trioste*, Fr. *Dreisteinwurzel*, G. (Nat. ord. Caprifoliaceæ.) This plant is found in most parts of the United States, preferring a limestone soil and shady situations. The root, the part used, is horizontal, long, about three-quarters of an inch in diameter, thicker and tuberculated near the origin of the stem, of a yellowish or brownish color externally, whitish within, and furnished with fibres which may be considered as branches of the main root. When dry it is brittle and easily pulverized. On microscopic examination, numerous crystals of calcium oxalate are to be seen. It has a sickening odor, and a bitter, nauseous taste. It is said to contain an alkaloid which Andree believed to be identical with emetine, but which Hartwich has shown to be different. It yields its active properties to both water and alcohol. Fever-root is cathartic, and in large doses emetic, and perhaps diuretic. The bark of the root may be given in doses of twenty or thirty grains (1·29–1·94 Gm.), or the extract in half the quantity. For uses, see *A. J. P.*, 1891, 326.

TRIPHENIN. *Propionyl-phenetidin.* $C_6H_4.C_2H_5O.NH.(CH_3.CH_2.CO)$. A homologue of phenacetin, made by boiling a mixture of paraphenetidin with propionic acid; it forms colorless, odorless crystals, fusing at 120° C., of feebly bitter taste, soluble in 2000 parts of water.

Triphenin has been used to a very limited extent, in doses of from eight to fifteen grains (0·5–0·9 Gm.), as an antipyretic in *typhoid fever*, *pneumonia*, and other acute affections, and also as an analgesic for nervous pains. Its range of action is precisely that of phenacetin. It is stated that it acts promptly, mildly, and without untoward secondary effects.

TRIPOLI. *Terra Tripolitana.* An earthy mineral, of a whitish, yellowish, or pale straw color, sometimes inclining to red or brown, usually friable, often adhesive to the tongue, and presenting the aspect of argillaceous earth, though differing from clay by the roughness and hardness of its particles, and by not forming a paste with water. The *Venice tripoli* is said to come from Corfu. Tripoli is sometimes artificially prepared by calcining certain argillites. It is used for cleaning and polishing metals.

TROMPATILA. This is the stem and branches of *Bouvardia triphylla*, Salisb. (nat. ord. Rubiaceæ), a Mexican plant used by the natives for *hydrophobia.* (*A. J. P.*, 1874, 51.)

TULIPINE. An alkaloid extracted from the garden tulip. It is said to be a cardiac poison, with remarkable sialagogue properties. (*Nouv. Rem.*, 1886.)

TUMENOL. A dark brown or blackish-brown liquid, of a syrupy consistence, which is made from bituminous shale oils. These are agitated with sodium hydrate to remove phenols and then with sulphuric acid to remove pyridine and other bases. The oil is then treated with fuming sulphuric acid. The dark syrupy liquid which separates is washed with water and dissolved in caustic soda. From this solution ether extracts *tumenol oil.* Hydrochloric acid, on the other hand, if added to the sodium hydrate solution, throws down *tumenol-sulphonic acid.* A mixture of these two substances constitutes *tumenol venale*, a soft, resinous, odorless mass. Prof. A. Neisser (*Deutsch. Med. Wochens.*, 1891) highly commends tumenol as a local application in *eczema*, and as having extraordinary powers over the itching of *prurigo*, *parasitic dermatitis*, and other *skin affections.* He uses a lotion made with equal parts of ether, rectified spirits, and water or glycerin, and 10 per cent. of tumenol.

Tumenol-sulphonic acid is similarly used as a dusting powder or in from 2 to 5 per cent. ointment.

TURPETHUM. *Turpeth. Resin of Turpeth. Résine de Turbith*, Fr. This product is obtained from the *Ipomœa turpethum*, R. Br. (*Convolvulus turpethum*, Linn.), an East Indian plant. Mérat and De Lens describe the root, the only part used, as "long, of the size of the little finger or larger, covered by a rather thick bark, grayish without, white within, porous, liable to decay, very resinous when fresh, and in this state yielding a juice capable of coagulating, and constituting, when coagulated, a gum-resin similar to scammony." In choosing the roots, those should be selected in which the bark is perfect, as most of the activity of the root resides in this part. It is without odor, and has little taste. Examined by M. Boutron-Chalard, it was found to contain resin, a fatty substance, volatile oil, albu-

men, starch, a yellow coloring matter, lignin, salts, and ferric oxide. (*Journ. de Pharm.*, viii. 121.) The root contains 10 per cent. of resin. (M. Andouard, *Ann. de Thérap.*, 1866, 118.) According to M. Spirgatis, this resin is a glucoside, *turpethin*, $C_{76}H_{128}O_{36}$, like that of other Convolvulaceæ, insoluble in ether, but soluble in alcohol, to which it imparts a brown color not removable by animal charcoal. To obtain it pure, the alcoholic solution is concentrated; the resin precipitated by, and afterwards boiled with, water, then dried, reduced to powder, digested with ether, and finally redissolved by absolute alcohol, and thrown down by ether. After being treated several times in this way, it is obtained in the state of a brownish resin, yielding on pulverization a gray powder, which strongly irritates the mucous membrane of the nostrils and mouth, and fusible at 360° F. It is inflammable, burning with a smoky flame, and emitting irritant vapors. With strong bases it acts like jalapin, takes up water, and is transformed into a soluble acid, *turpethic acid*, $C_{38}H_{76}O_{24}$, while with dilute acids it is decomposed into *turpetholic acid*, $C_{16}H_{32}O_4$, and glucose. (*Journ. de Pharm.*, 4e sér., i. 236.) Turpeth root is purgative, somewhat less powerful than jalap, and rather slow in its action. From one to three drachms may be given in decoction, and from fifteen grains to a drachm in powder. (Mérat and De Lens.) M. Andouard states that the resin purges perfectly well in doses of seven or eight grains (0·45 or 0·5 Gm.), though perhaps somewhat less active than jalap or scammony. (*Ann. de Thérap.*, 1866.)

TURTLE OIL. In South America an oil is prepared from the eggs of turtles, and in the Seychelle Islands and in Jamaica from the fat of the turtle itself. These oils are said to be of equal value with cod-liver oil in strumous persons and others in whom the nutritive processes are defective. (See *P. J. Tr.*, vol. xv. 573.) It is stated that 50,000 gallons are sent to Pará yearly from the Orinoco, the Amazon, and the Rio Negro, and that 60,000 gallons are consumed by the tribes who prepare the oil. The Seychelle Islands are said to produce 6000 gallons of oil yearly.

TUSSILAGO FARFARA. L. *Coltsfoot. Folia Farfaræ*, P. G. *Tussilage, Pas d'âne*, Fr. *Huflattig, Rosshuf*, G. (Nat. ord. Compositæ.) Coltsfoot is a perennial herb, with a creeping root, which early in the spring sends up several leafless, erect, simple, unifloral scapes or flower-stems, five or six inches high, and bearing appressed scale-like bracts of a brownish-pink color. The flower, which stands singly at the end of the scape, is large, yellow, compound, with hermaphrodite florets in the disk, and pistillate, fertile florets in the ray. The latter are numerous, linear, and twice the length of the former. The leaves do not make their appearance until after the flowers. They are radical, petiolate, large, cordate, angular, toothed at the margin, bright green upon their upper surface, white and downy beneath. The plant grows spontaneously both in Europe and North America. In this country it is found upon the banks of streams from Nova Scotia and New Brunswick south to New York and west to Minnesota. It flowers in April and June. The whole of it is employed, but the leaves most so. They should be gathered after their full expansion, but before they have attained their greatest magnitude. The flowers have an agreeable odor, which they retain after desiccation. The dried root and leaves are inodorous, but have a rough, bitterish, mucilaginous taste. Boiling water extracts their virtues. Mr. C. S. Bondurant (*A. J. P.*, 1887, 340) examined coltsfoot chemically. He found evidences of a bitter glucoside. Coltsfoot exercises little sensible influence upon the human system. It is, however, demulcent, and is sometimes used in *chronic coughs*, *consumption*, and other *affections of the lungs*. The expectorant properties which it was formerly thought to possess are not obvious. The leaves were smoked by the ancients in *pulmonary complaints*, and in Germany they are said to be substituted for tobacco. Cullen used the fresh juice in *scrofula*, several ounces daily. The decoction (℥i to Oi) is commonly given in teacupful doses.

TUSSOL. *Antipyrine Mandelate* (*Phenyl-glycolate*). $C_{11}H_{12}N_2O.C_6H_5CH(OH)COOH$. It is soluble in water, and is recommended in the treatment of whooping-cough in the following doses: for children under one year, from three-fourths to one and a half grains (0·05–0·1 Gm.); from two to four years, four to six grains (0·25–0·4 Gm.).

TUTTY. *Tutia. Impure Oxide of Zinc.* This oxide is formed during the smelting of lead ores containing zinc. It is deposited in the chimneys of the furnaces, in the form of incrustations, moderately hard and heavy, and studded over with small protuberances of a brownish color on the outside and yellowish within. As it occurs in commerce, the pieces occasionally present a bluish cast, from the presence of small particles of metallic zinc. Sometimes a spurious substance is sold for tutty, consisting of a mixture of blue clay and copper filings, made into a paste with water and dried on an iron rod. It is distinguished from the genuine tutty by its diffusing in water and exhaling an earthy smell, and by its greater friability. Tutty is used solely as an external desiccant. To fit it for medicinal use it must be reduced to fine powder, which is dusted over the affected part, or applied in the form of ointment.

TYLOPHORA ASTHMATICA. Wight and Arn. (Nat. ord. Asclepiadaceæ.) The leaves of this plant are official in the Pharmacopœia of India as a substitute for ipecacuanha. Broughton obtained from them organic crystals, and David Hooper (*P. J. Tr.*, Jan. 1891) has shown that the root contains an alkaloid, *tylophorine*.

ULEX. *Ulex Europæus*, L. (nat. ord. Leguminosæ), is the common *furze*, *gorse*, or *whin* so conspicuous in the waste places and by the roadsides of Great Britain, from its spiny branches and bright yellow flowers situated on the spines, either solitary or in pairs. In the seeds of this plant Mr. A. W. Gerrard has found an alkaloid, *ulexine*. In 1890 Prof. Kobert (*Deutsch. Med. Wochensch.*, 1890), as the result of an elaborate physiological study, came to the conclusion that ulexine and cytisine are identical. The suggestion has given rise to a considerable chemico-physiological discussion, a brief abstract of which may be found in the *P. J. Tr.*, Feb. 1891. Prof. Kobert found indications of a second alkaloid in ulex. Partheil (*Archiv der Pharm.*, 1892, 448; 1894, 486) and Plugge (*Archiv der Pharm.*, 1894, 444) are in accord as to the identity of ulexine and cytisene. Ulexine has been used in cardiac *dropsy*. Dose, from one-fifteenth to one-twentieth of a grain (0·004–0·0032 Gm.).

ULTRAMARINE. *Outremer*, Fr. *Ultramarin*,

G. This fine blue pigment was formerly obtained from *lapis lazuli*, or *lazulite*, a mineral of Siberia. It is now prepared artificially on a very large scale. In preparing it, a mixture of soft clay with Glauber salt, charcoal, soda, and sulphur is heated in crucibles. In this way a colorless compound is first produced, termed white ultramarine. This, however, soon becomes of a green color. The green ultramarine thus obtained, which is also used as a color, is then mixed with sulphur and heated. The sulphur takes fire and is allowed to burn in the air, when the product becomes of a fine blue color. (*Roscoe and Schorlemmer*, vol. ii. 459.) It is thought to be a compound of aluminum and sodium silicates with sodium polysulphide, although the sulphur present is retained in two conditions, part being deposited when ultramarine is treated with acids and part escaping as hydrogen sulphide.

UMBELLULARIA CALIFORNICA. Nutt. *California Laurel. Spice-tree.* (Nat. ord. Laurineæ.) The leaves of this California shrub are employed in *neuralgic headaches*, and in *intestinal colic* and *atonic diarrhœa;* also externally as a mild counter-irritant. Stillman and O'Neill (*New Rem.*, 1883) obtained from the seeds a new acid, *umbellulic acid*. The leaves are said also to contain about 4 per cent. of a volatile oil, having a specific gravity of 0·936, a warm camphoraceous taste, and a strong pungent odor. Burse has separated from the oil by fractional distillation *umbillol*, an oil having the formula $C_8H_{12}O$, which dissolves in concentrated sulphuric acid with red color, and is narcotic. (*Apotheker Zeitung*, xi.) According to Schimmel & Co. (*Report* of April, 1897), it also contained *cineol*, $C_{10}H_{18}O$. The fluid extract has been used in doses of from ten to thirty minims (0·616–1·84 C.c.). It is probable that the volatile oil is a strong local anæsthetic, as it has been found to act rapidly when brought in contact with exposed pulp or sensitive dentine.

UMBER. *Terra Umbra.* A mineral of a fine compact texture, light, dry to the touch, shining when rubbed by the nail, and of a fine pale brown color, which changes to a peculiar beautiful deep brown by heat. According to Klaproth, it contains 13 parts of silica, 5 of alumina, 48 of ferric oxide, 20 of manganese, and 14 of water in 100. *Burnt umber*, as well as the mineral in its unaltered state, is used in painting. The umber of commerce is said to be brought chiefly from the island of Cyprus.

URANIUM. Atomic weight 238·8. The salts of the metal uranium are violent poisons, producing not only severe gastro-enteritis and nephritis, but also acting specifically on the hæmoglobin of the blood, affecting its oxygenating powers. (See *P. J. Tr.*, Sept. 1890.) They have been used on the principle of *similia similibus curantur* in renal diseases, and West affirms that the *uranium nitrate* is useful in *diabetes mellitus*. Dose, from one to two grains three times a day, increased to thirty grains a day.

UREA. $CO(NH_2)_2$. *Carbamide. Urée*, Fr. *Harnstoff*, G. For an account of the physical and chemical properties of urea, the reader is referred to treatises upon physiology. Urea has been employed in practical medicine as a hydragogue diuretic in the treatment of *dropsies*. The commencing dose for the adult is ten grains (0·648 Gm.) every six hours. (See *Braithwaite's Retrospect*, xxv.)

Thio-urea is a substance in which one atom of oxygen in a molecule of urea is replaced by an atom of sulphur, $CS{<}^{NH_2}_{NH_2}$. According to Paul Binet (*Revue Méd. de la Suisse Romande*, 1893), it is a very active poison, paralyzing the nerve-centres but leaving intact the peripheral nerves and the muscles.

URECHITES SUBERECTA. Muell. Arg. *Savannah Flower. Yellow-flowered Nightshade.* This is an apocynaceous plant, which grows abundantly in the West Indian Islands, and is said to be used in Jamaica by the negroes as a poison. The symptoms which it produces are violent vomiting and purging, with convulsions. Mr. J. J. Bowrey (*Journ. Chem. Soc.*, June, 1878) has isolated from it two glucosides, *urechitin* and *urechitoxin*, having respectively the formula $C_{26}H_{42}O_8$ and $C_{13}H_{20}O_5$. Dr. Isaac Ott (*T. G.*, 1880) finds the plant to be a powerful cardiac poison, first increasing and then depressing the arterial pressure, and finally, if the dose be large enough, killing by producing cardiac arrest. The results reached by Dr. Ott are in accord with those of Dr. Ralph Stockman (*Laborat. Rep., Royal College Physicians Edinburgh*, vol. iv., 1892), who finds that both of the glucosides are very active poisons belonging to the digitalis group. On the other hand, Vowinkie came to the conclusion that even small doses of the plant depress the heart; and experiments made upon man by Mr. Bowrey show that in large doses the drug produces nausea, vomiting, general depression, great perspiration, and slight slowing of the pulse. Stockman (*Rev. de Clin. et de Thér.*, June 29, 1892) found that the leaves contain a toxic alkaloid, which he calls *urechitine*, $C_{26}H_{42}O_8 + H_2O$, and a glucoside, *urechotonin*, which is less toxic. In Jamaica the drug is said to have been used in the treatment of *intermittent* and other *sthenic fevers*. The dose of the fluid extract is from two to ten minims (0·13–0·65 C.c.).

URETHANE. *Ethyl Carbamate. Uréthane*, Fr. *Urethan*, G. $CO.(NH_2)OC_2H_5$. This is made by allowing ammonia to act upon ethyl carbonate, when urethane and ethyl alcohol are produced, or by heating urea nitrate with alcohol to from 120° to 130° C., when ammonia will be liberated. It forms colorless crystals of slight ethereal odor and taste resembling that of saltpetre, which are soluble in water and alcohol. The melting point of urethane is from 47° to 50° C., and it boils without decomposition at 180° C. When it is heated with ammonia to 180° C., urea is formed.

Urethane produces in the lower animals a brief period of excitement, with quickened respiratory and cardiac action, which is followed by deep sleep, with slowing of the respiration. If a fatal dose has been taken, the respiration becomes slower, the unconsciousness absolute, the reflexes are abolished, and a pronounced fall of bodily temperature occurs, with marked weakness of the cardiac action, and finally death from asphyxia. The lessening of reflex action is primarily due to an influence upon the spinal cord, although the irritability of the motor nerves is said to be lessened. The psychomotor centres in the cerebral cortex, according to Von Anrep, suffer decrease of faradic excitability under the influence of decided doses. Urethane has been used to a considerable extent by clinicians as an hypnotic, but the reports as to its action are very contradictory. Thus, it is commended by

Drs. Sticker, Myrtel, Rottenviller, and Kraepelin, whilst Drs. Bock and Koenig condemn it. It has been used hypodermically by Koenig in doses of as high as twenty-one grains (1·3 Gm.) without success. By the mouth, according to Kraepelin, a full dose is forty-five grains, but seventy-five grains have been given. It appears to have no analgesic effect. It has been used by Jackman (*Lancet*, June, 1886) in *traumatic tetanus* with success after the failure of chloral. Four grains were given, to a boy aged fifteen, every two hours.

URICEDIN. Prepared by clarifying lemon-juice, and adding for every fifty parts of citric acid in it, twenty parts of sulphuric acid, four parts of 25 per cent. hydrochloric acid, and sufficient sodium carbonate to nearly neutralize the acids. One part of lithium carbonate, neutralized with lemon-juice, is then added, and the whole evaporated and granulated. It contains sodium sulphate, chloride, and citrate, with lithium citrate. Used in *gout* and *rheumatism*.

URISOLVIN. A compound of pure urea and acid lithium citrate, used as a diuretic, and uric acid solvent in doses of three grains (0·2 Gm.) in the form of tablets.

UROPHERIN. *Lithium-diuretin. Theobromine-lithium-salicylate.* $C_7H_7N_4O_2Li + C_6H_4(OH)COOLi$. A compound analogous to diuretin, lithium being substituted for sodium. Used as a diuretic in doses of fifteen grains (0·9 Gm.). E. Merck has also introduced the corresponding benzoate under the same name, uropherin.

UROTROPINE. *Urotropin Hexamethylenetetramine. Formin. Aminoform.* $C_6H_{12}N_4$. Hexamethylenetetramine is obtained, according to Nicolaier (*Les Nouv. Rem.*, xi.), by passing a current of dry ammonia gas over warm trioxymethylene (paraformaldehyde). It crystallizes from alcohol in rhomboidal crystals, which are readily soluble in water, slightly soluble in alcohol, and almost insoluble in ether. Urotropine was first introduced into medicine by Bardet (*Les Nouv. Remèdes*, 1894) and Laquers on theoretical grounds, they having found it to be free from toxic action in animals, and capable of dissolving uric acid readily. Nicolaier (*Deutsch. Med. Wochensch.*, 1895) confirmed these statements and pointed out other important properties of the drug. Since the publication of these articles urotropine has been used and reported upon by a number of surgeons and clinicians, especially by Casper (*Deutsch. Med. Wochensch.*, 1897), Loebisch (*Wiener Klin. Wochensch.*, 1897), Flexner (*American Pract. and News*, 1895), and Bardet.

When given in sufficient dose urotropine markedly increases the flow of urine, and causes that fluid to be free from tendency to undergo rapid putrefaction. The urine is not only acid at the time of its expulsion, but remains so for many days. In moderate dose urotropine produces no distinct symptoms, but after from ninety to one hundred and twenty grains a day there is often burning pain in the bladder and urethra, especially after urination; if the administration be continued, there appears a large urinary sediment, containing much epithelium and red blood-corpuscles. In rare cases even the moderate dose produces albuminuria and other evidences of renal irritation.

Urotropine is rapidly absorbed, and is certainly in part excreted unchanged. In less than half an hour after its ingestion the urine usually affords with bromine water an orange-yellow precipitate of the urotropine dibromide. The presence of urotropine in the urine has been demonstrated twenty-seven hours after the taking of the last dose. Nevertheless, the theory first brought forward by Loebisch, that it is decomposed in the system with a setting free of formaldehyde, has received confirmation at the hands of Casper, who states that he has found formaldehyde in the blood of the rabbit into which he had injected urotropine hypodermically, and has also been able in some cases to detect formaldehyde in the urine of persons taking urotropine, though in other cases no formaldehyde could be made out. It would appear, therefore, that urotropine is partially decomposed in the system and partially eliminated unchanged. An observation of Casper that formaldehyde is given forth for days by the urine of persons who have taken urotropine indicates that the urotropine undergoes decomposition in the urine itself after its secretion by the kidneys. It has been established by both laboratory and clinical experience that the power of urotropine as a solvent of uric acid is not superior to that of piperazine, and that it is really of no value for the solution of *renal calculi*. On the other hand, it ranks with piperazine as one of the minor remedies, useful in a *uric acid diathesis* as a succedaneum to the salicylates. It appears to be a distinct addition to the list of remedies used in the treatment of *pyelitis* and *cystitis;* by reason of its checking fermentation and modifying the almost always coexisting inflammation of the mucous membrane, it is a valuable remedy in the treatment of *phosphaturia*. A. Citron (*Monats. d. Harn. u. Sexual-Appa.*, 1898) suggests that the good achieved in these cases depends upon the liberation of formaldehyde in the urine, and that this does not occur when the urine remains alkaline; so that it is essential in any case to see that the urine becomes acid during the administration of the urotropine. Urotropine has proved of no service in *gonorrhœa*. The dose is from five to fifteen grains (0·3–0·9 Gm.), given dissolved in half a tumbler of effervescent or simple water four times a day. According to Citron (*loc. cit.*), its presence in the urine can be determined for at least twenty-four hours after administration. The method employed is as follows. The urine which it is desired to test is slightly acidified and then placed in a flask or test-tube and boiled; over the mouth of the tube is placed a cotton plug soaked with a solution of resorcin in sodium hydrate. The formaldehyde is decomposed into formic acid and methyl alcohol, and gives a brilliant red color to the resorcin mixture. When the urine is highly alkaline a reaction for formalin cannot be obtained, a fact which illustrates the absolute necessity of keeping the urine sharply acid while treating a patient with urotropine, for otherwise no formalin is set free, and therefore the well-known antiseptic action of the latter will not be obtained.*

URSAL. A compound of urea and salicylic acid, used as a substitute for sodium salicylate.

URTICA. *Ortie brûlante*, Fr. *Brennessel*, G.

*To avoid possible confusion, the reader should know that the name *urotropine* is employed as synonymous with hexamethylenetetramine by all recent writers, although it was early used by Nicolaier as the name of a *combination of hexamethylenetetramine with uric acid*.

Urotropine salicylate, proposed by Flexner, contains about 50 per cent. each of salicylic acid and urotropine, and is evidently not suitable for use as a salicylate in *rheumatism*. Its value in *cystitis* has not been determined.

Various species of this genus are furnished with poisonous stinging hairs. *Urtica gigas* of Australia is said frequently to kill horses, and to produce in man a sting whose impression lasts for months. (*N. R.*, 1875.) It has generally been thought that the virulence of the hairs is due to the presence of free formic acid (*A. J. P.*, xxii.), and David Hooper (*P. J. Tr.*, April, 1887) has demonstrated the presence of formic acid, or a substance very closely allied to it, in the hairs of the *Nilgri nettle* (*Girardinia palmata*). Nevertheless, it does not seem probable that formic acid is the poison. Dr. G. Haberlandt believes it to be a non-volatile albuminoid; and L. Reuter has obtained from several nettles a glucoside. (*A. J. P.*, Jan. 1890.) Oddi and Lomonaco (*Rif. Med.*, April, 1892) isolated from the common nettle a crystalline alkaloid, and found that in mammals the extract acts powerfully upon the vaso-motor system, and in frogs causes centric paralysis with diastolic cardiac arrest.

U. dioica, or common nettle, and *U. urens*, or dwarf nettle, of America and Europe, have been used in medicine as local irritants, as diuretics (*A. J. P.*, 1866), and especially for the purpose of arresting *uterine hemorrhage*. The fluid extract may be given in doses of half a fluidrachm (1·84 C.c.) or a decoction of an ounce to a pint in teacupful dose.

USTILAGO. *U. S.* 1880. *Corn Smut.* The genus Ustilago belongs to the fungoid order of Ustilaginaceæ, an order of the Hemibasidii, all the members of which generally develop their spores in the ovary or anthers of the host plant, forming a slimy mass, which in maturing becomes a black dust made up of spores. They produce the *smut* in cereals. *Ustilago Maydis* (D. C.), Tul., is produced on the stems, the pistils (corn grains), and the male inflorescence (tassel) of the Indian corn. It is specifically characterized by its minute spherical spores, having their surface covered with echinulate warts. It is abundant in the United States. Upon the corn the smut appears in masses, varying in size from a cherry to a child's head. These masses are smooth, irregularly globose, or sometimes lobulated, having at first a livid, bluish tint, and then becoming blackish, and finally bursting and emitting the black contents, consisting of innumerable globose very minute spores, each of which is covered with beautiful little pointed processes. In a dried state the masses are blackish and covered with a black powder.

In the smut Mr. C. H. Cressler found an alkaloid, which he considered to be identical with *secaline*, a supposed alkaloid of ergot. This has since been shown to be *trimethylamine*, and to be, moreover, a decomposition product, and not to exist originally in the ergot. Whether the alkaloids since discovered in ergot by Tanret and Dragendorff exist in ustilago has not been ascertained. Besides the alkaloid, there were obtained a thick, viscid, fixed oil, a resin soluble in ether but not in alcohol, pectin, gluten, and a species of sugar. (*A. J. P.*, 1861, 306.) Messrs. Rademaker and Fischer (*Nat. Drug.*, 1887, 296) assert that they have separated a crystalline alkaloid from the corn smut, which they name *ustilagine*. It is said to be white, of a bitter taste, soluble in ether, alcohol, and water, yielding crystallizable salts which are also soluble in water. Propylamine and sclerotic acid (*maizenic acid*) were also found in the smut. Prof. H. B. Parsons analyzed ustilago, and found in it fixed oil, an amine-like volatile substance extracted by ether, which he states is not an alkaloid nor is it trimethylamine, and an acid which he has provisionally named sclerotic acid, because of its apparent similarity to the acid discovered by Dragendorff in ergot. (*N. R.*, March, 1882. See also *West. Drug.*, 1894, 88.) Corn smut is said to produce abortion in cows and in bitches. (*A. J. P.*, Sept. 1861, 413.) Dr. W. A. N. Dorland has found that in doses of from one to two drachms of the fluid extract it markedly increases the uterine pains during *labor*. He asserts for it that it will not produce a prolonged tonic contraction as does ergot. This is, however, doubtful.

VACCINIUM CRASSIFOLIUM. Andr. (Nat. ord. Vacciniaceæ.) The leaves of this American shrub are said to be astringent and diuretic, and capable of replacing uva ursi. Dose of the fluid extract, from a half to one fluidrachm (1·9–3·8 C.c.).

VALERIANIC ACID. *Valeric Acid. Acidum Valerianicum.* $HC_5H_9O_2$. Mol. wt. 102. *Acide valérianique*, Fr. *Valeriansäure Baldriansäure*, G. *Acido valerianico*, It., Sp. *Acidum valericum. Acide valérique.*

In the 1860 U. S. revision this acid was transferred from the Preparations to the Materia Medica list; in that of 1880 it was dropped entirely. "Valerianic Acid is a colorless liquid, of an oily consistence, a penetrating, disagreeable odor, and caustic taste; and of the sp. gr. 0·935." *U. S.* 1870.

"Take of Valerianate of Soda, in coarse powder, *eight troyounces;* Sulphuric Acid, Water, each, *a sufficient quantity.* To the Valerianate of Soda add, first, three fluidounces of Water, and then three troyounces and a half of Sulphuric Acid. Mix them thoroughly, and from the mixture, after standing, separate the oily acid liquid which rises to the surface. Agitate this repeatedly with small portions of Sulphuric Acid until its specific gravity is reduced below 0·950. Then introduce it into a retort, and distil nearly to dryness, rejecting the distillate so long as it has a specific gravity above 0·940, and keeping the remainder for use. The rejected portion of the distillate, after agitation with Sulphuric Acid, may be returned to the retort during the progress of the distillation." *U. S.* 1870.

The object of this process is merely to procure valerianic acid in a state adapted for the preparation of ammonium valerianate. The sulphuric acid, uniting with the soda of the sodium valerianate, separates the valerianic acid, which rises to the surface with the appearance of an oil. In this state it is still mixed with water, and, as the pure acid is wanted, the direction is given to agitate it with sulphuric acid, which deprives it of the excess of water. It is now distilled in order to separate any sulphuric acid and water that may be mixed with it. The process is that of Mr. B. J. Crew, published in *A. J. P.*, 1860, 109. Mr. F. C. Musgiller, of Brooklyn, N. Y., stated that the acid cannot be obtained by the process of 1860 of a sp. gr. as low as 0·933 with ordinary sulphuric acid, and suggested that 0·935 be adopted as the official standard; as acid of this strength is equally well adapted for the preparation of the valerianates, for which alone it is used. This suggestion, as to the sp. gr., was adopted at the revision of the U. S. Pharmacopœia of 1870. Mr. Musgiller proposes some modifications of the process which appear to be judicious. (See *A. J. P.*, 1869, 83; also *Proc. A. P. A.*, 1868.)

For modes of preparing valerianic acid from the oil and roots of valerian, the reader is referred to the article on Valerian in this work. It is prepared

also from amylic alcohol by reaction with a mixture of potassium bichromate and sulphuric acid, as the first step in the preparation of sodium valerianate.

Valerianic acid received its name from having been found in the oil distilled from the root of *Valeriana officinalis*, L. (nat. ord. Valerianaceæ). It is sometimes called also *valeric acid*. It was first obtained in 1817 by Chevreul from the oil of the dolphin, and received the name of *delphinic acid*, which, however, upon the discovery of its identity with the acid afterwards obtained by Pentz from valerian, was superseded by its present title. It has been obtained also from the bark and fruit of *Viburnum opulus*, L., and other species of Viburnum (nat. ord. Caprifoliaceæ), the sap-wood of the European elder (*Sambucus nigra*, L.) (nat. ord. Caprifoliaceæ), the root of *Angelica archangelica*, L. (*Archangelica officinalis*, Hoffm.) (nat. ord. Umbelliferæ), and from various organic products whether of the vegetable or animal kingdom.

Properties. Valerianic acid is a colorless liquid, of an oily consistence, a repulsive odor, resembling, however, that of valerian, and a pungent, sour, acrid, disagreeable taste. Its sp. gr. is variously given from 0·946 at 0° C. to 0·931 at 20° C. (Beilstein, *Org. Chem.*, i. 406.) As stated in the U. S. P. 1870, it is 0·935. It remains liquid at 8° below zero, and boils at 174° C. (345·2° F.). (Trommsdorff.) It is soluble in thirty parts of cold water, and when agitated with water takes up about 20 per cent., without losing its oily consistence, and rises to the surface of the liquid. Alcohol and ether mix with it in all proportions. It is very soluble in strong acetic acid, and dissolves camphor and some resins. (Trommsdorff.) It forms salts with the alkalies, and reddens litmus-paper strongly, but the blue color gradually returns in a warm place. Its composition is represented by $C_5H_{10}O_2$, and it is a mixture of two isomeric acids (*isovaleric acid* and optically active valeric acid). This is true as well of the valeric acid that is obtained from the *Valeriana officinalis*, L., the *Angelica archangelica*, L., and that which results from the oxidation of the amyl alcohol of fermentation with the aid of chromic acid. The strong acid readily unites with a molecule of water to form a hydrated acid. $C_5H_{10}O_2 + H_2O$. This compound, formerly known as the *terhydrate*, has a sp. gr. 0·945, and boils at a lower temperature than the strong acid. It has a much milder taste than the pure acid, and is at the same time somewhat saccharine. The U. S. P. 1870 gave the following tests of the official acid. "A solution of Valerianic Acid, in fifty parts of hot water, saturated with hydrated carbonate of zinc, yields a liquid, which, when filtered and evaporated to ten parts and cooled, affords white pearly crystals of valerianate of zinc. The mother-water, drained from these crystals, should not yield, by further evaporation and cooling, a salt crystallizing in six-sided tables, and very soluble in water. When the Acid is added to a concentrated solution of acetate of copper, the transparency of the solution is not disturbed." The former of the last two tests indicates the absence of acetic, the latter of butyric acid. The acid distilled from the oil or root of valerian has been employed in *nervous affections*, and possesses properties similar to those of valerian. According to Landerer, the acid artificially produced does not operate therapeutically so satisfactorily as the native product. The dose would probably be about the same as that of the oil of valerian, given in sweetened water.

VALERIDIN. *Valerydin. Sedatin. Iso-valeryl-p-phenetidine.* $C_6H_4\begin{cases}NHCOC_4H_9\\OC_2H_5\end{cases}$. This substance occurs as white, glistening needles, which are readily soluble in alcohol or chloroform, difficultly soluble in ether, and almost insoluble in water. It is obtained by heating isovaleric acid with p-phenetidine. C. Erdmann (*Pharm. Zeit.*, xliii) commends this substance in doses of from eight to fifteen grains (0·5–0·9 Gm.) a day, as a succedaneum for valerianic acid, and as being very serviceable in *migraine*, *neuralgia*, and *hysteria*.

VALIDOL. *Valeric-acid-menthol-ester.* According to G. Schwersenski (*Therap. Monats.*,1897), this is a chemically pure compound of menthol and valerianic acid, containing about 30 per cent. of free menthol. It is a colorless liquid of the consistency of glycerin, having a mild, pleasant odor, and a cool, faintly bitter taste. It is recommended by its discoverer in doses of from ten to fifteen drops as a carminative and stimulant in *hysteria* and *neurasthenia*. As it will still dissolve menthol freely, it affords a method of applying that drug in the form of sprays or with a brush in diseases of the nose and throat.

VALONIA. *Acorn Cups. Valloné*, *Vélanède*, *Gallon*, Fr. *Knoppern*, *Walonen*, G. The great cups of the acorns of the *Quercus ægilops*, L. (nat. ord. Cupuliferæ), a native of Bosnia, contain a very large percentage of tannin. They are extensively exported for dyeing and tanning, and have been employed as an astringent in *diarrhœa*.

VANDELLIA DIFFUSA. (L.) (Nat. ord. Labiatæ.) This is an herb of Paraguay, said to be used by the natives as an emetic. (*P. J. Tr.*, 1872, 849.)

VASELINUM OXYGENATUM. *Vasogen.* This is a feebly alkaline, yellow-brown fluid, of a peculiar but not disagreeable odor and taste, which readily emulsifies with water. It is said to be oxygenated vaseline or petrolatum, and again that it contains about 25 per cent. of olein, saponified with anhydrous ammonia, and mixed with vaseline and vaseline oil. Vasogen serves as a vehicle for ointments whose active ingredients, it is said, are absorbed with great rapidity from the skin. There have been offered camphor vasogen, 33½ per cent.; iodine vasogen, from 3 to 10 per cent.; menthol vasogen, 2 per cent.; and the list might be extended almost indefinitely. There does not seem to be any reason for supposing that the vasogen ointments are really superior to ointments made with vaseline.

VENETIAN RED. *Bolus Veneta.* A dull red ochrey substance used in painting.

VERATRUM ALBUM. L. *White Hellebore. Rhizoma Veratri*, P. G. *Ellebore blanc*, Fr. *Weisse Niesswurzel*, G. *Elleboro bianco*. It. *Veratro blanco*, Sp. (Nat. ord. Liliaceæ.) White hellebore is a native of the mountainous regions of continental Europe, and abounds in the Alps and Pyrenees. It so closely resembles *V. viride* both in appearance and minute characteristics that the specific distinction of the two is very doubtful. All parts of the plant are said to be acrid and poisonous, and the rhizome was formerly official. This is brought from Germany in the dried state, in pieces from one to three inches long by an inch or less in mean diameter, cylindrical or in the shape of a truncated cone, internally whitish, externally black-

ish, wrinkled, and rough with the remains of the fibres which have been cut off near their origin. Sometimes the fibres continue attached to the root. They are numerous, yellowish, and of the size of a crow's quill White hellebore deteriorates by keeping. The fresh root has a disagreeable odor, which is lost by drying. The taste is at first sweetish, and afterwards bitterish, acrid, burning, and durable. The powdered root is grayish. Analyzed by Pelletier and Caventou, white hellebore was found to contain an oily matter consisting of olein, stearin, and a volatile acid; *veratrine*, $C_{32}H_{52}N_2O_8$ (Merck), in combination with gallic acid; a yellow coloring matter; starch, gum, and lignin; silica, and various salts of calcium and potassium. The existence of gallic acid in veratrum was, however, denied by Pfaff and by Wiegand. The medicinal properties of the root were believed to reside in the veratrine, which was first discovered in the seeds of *Veratrum sabadilla*. Simon found *jervine*, $C_{30}H_{46}N_2O_3$, in white hellebore. Chas. Bullock, Chas. L. Mitchell, and A. Tobien confirmed the presence of *jervine*, the formula of which, however, according to Tobien, is $C_{27}H_{47}N_2O_8$. Wright and Luff (*Journ. Chem. Soc.*, xxxv. 405) found *jervine*, *rubijervine*, and *pseudojervine*. Charles. L. Mitchell discovered a second alkaloid, *veratralbine*, $C_{28}H_{43}NO_5$, the presence of which has been confirmed by Wright and Luff and other investigators. For most recent views as to composition of veratrine by Wright and Luff, see *Veratrina*, PART I. Two investigations have since been made of the alkaloids of *V. album* by Pehkschen and Salzberger respectively (*A. J. P.*, 1891, 196 and 292). Pehkschen found *veratroidine*, $C_{32}H_{53}NO_9$, *pseudojervine*, $C_{29}H_{49}NO_{12}$, and *jervine*, $C_{14}H_{22}NO_2$. Salzberger confirms the existence of the three crystalline alkaloids announced by Wright and Luff,—viz., *jervine*, $C_{26}H_{37}NO_3$, *pseudojervine*, $C_{29}H_{43}NO_7$, and *rubijervine*, $C_{26}H_{43}NO_2$, and asserts that he has found two additional ones, *protoveratrine*, $C_{32}H_{51}NO_{11}$, and *protoveratridine*, $C_{26}H_{45}NO_8$. White hellebore resembles very closely in the symptoms which it causes and in its physiological action veratrum viride; it is, however, more irritant and consequently more apt to purge severely than is that drug when taken in toxic doses. (See H. C. Wood and H. C. Wood, Jr., *Amer. Journ Med. Sci.*) It was at one time used as an errhine, but as such has passed out of vogue. In whatever way white hellebore is used, it requires cautious management. It has been given in doses varying from one grain to a scruple (0·065–1·29 Gm.). Not more than two grains should be administered at first.

VERBASCUM THAPSUS. L. *Mullein. Flores Verbasci*, P. G. *Bouillon blanc, Molène*, Fr. *Wollkraut, Königskerze*, G. (Nat. ord. Scrophulariaceæ.) The ordinary mullein weed is too well known to need description. As remedial agents, both leaves and flowers have been employed. They have a very slight odor, and a mucilaginous, herbaceous, bitterish, feeble taste. Mullein leaves are demulcent and emollient, and are thought to possess anodyne properties, which render them useful in pectoral complaints. On the continent of Europe, an infusion of the flowers, strained in order to separate the rough hairs, is considerably used in mild *catarrhs*. An oil, produced by saturating olive oil with mullein flowers, during prolonged exposure to the sun, is used as a local application in Germany for *piles* and other *mucous membrane inflammations*. The mullein oils sold in pharmacies are of this nature, or some of them alcoholic tinctures. The dried leaves are sometimes smoked to relieve irritation of the respiratory mucous membranes; fomentations with mullein leaves also have some repute as anodynes. Internally, the decoction (an ounce to the pint, flowering tips) may be taken in the quantity of from four to six fluidounces.

VERDITER. Two preparations of copper, employed as pigments, are known by this name in commerce, and are distinguished by the epithets of blue and green. *Blue verditer* is prepared in London from the solution of copper nitrate obtained in precipitating silver by copper. According to Gray, this solution is poured while hot upon whiting (calcium carbonate), and the mixture stirred every day till the liquor loses its color, when it is decanted, and fresh portions added till the proper color is obtained. By a process for procuring this pigment, invented by Pelletier, the solution of copper nitrate is decomposed by quicklime, and the precipitate, after being washed, is incorporated intimately with another portion of quicklime. By the former process, a copper carbonate is obtained; by the latter, a mixture of copper hydroxide and calcium hydrate. *Green verditer* is prepared by precipitating a solution of copper nitrate by chalk or a white marl, and consists of copper carbonate mixed with an excess of the calcareous carbonate.

VERNONIA ANTHELMINTICA. Willd. (Nat. ord. Compositæ.) This is an East Indian plant, whose black, bitter, and nauseous seeds have a high reputation in Ceylon as an anthelmintic in doses of sixty grains (3·9 Gm.). (*P. J. Tr.*, April, 1883; also *Pharm. Rev.* 1896, 274.)

VERONICA OFFICINALIS. L. *Speedwell. Véronique mâle*, Fr. *Ehrenpreis*, G. (Nat. ord. Scrophulariaceæ.) Several species of Veronica, common to Europe and this country, have been medicinally employed. Of these, *V. officinalis*, L., and *V. beccabunga*, (L. ?), or *brooklime*, are the most conspicuous. *V. officinalis* has a bitterish, warm, and somewhat astringent taste. Enz found in it a bitter principle soluble in water and alcohol, but scarcely so in ether, and precipitated by the salts of lead but not by tannic acid; an acrid principle; red coloring matter; a variety of tannic acid producing a green color with the salts of iron; a crystallizable fatty acid, with malic, tartaric, citric, acetic, and lactic acids; mannite; a soft, dark green, bitter resin. Prof. Mayer, of New York, found evidences of an alkaloid and of a saponaceous principle. (*A. J. P.*, 1863, 209.) The plant has been considered diaphoretic, diuretic, expectorant, tonic, etc., and was formerly employed in *pectoral* and *nephritic complaints*, *hemorrhages*, *diseases of the skin*, and in the treatment of *wounds*. *V. beccabunga* was used in the fresh state as a blood purifier and in *scurvy*.

VIEIRIN. This substance is obtained from the bark of the *Remijia vellozii*, D. C. (nat. ord. Rubiaceæ), of Brazil. It is used in Brazil in doses of from one to four grains (0·065–0·259 Gm.) repeated *pro re nata*, as a tonic and as an antiperiodic in place of quinine.

VINCA. Under the names *V. major*, L., *Greater Periwinkle*, and *V. minor*, L., *Lesser Periwinkle* (nat. ord. Apocynaceæ), are said to be very useful in arresting *menorrhagic* and other *hemorrhages*. (*P. J. Tr.*, 1871, 961; *Ibid.*, 1873, 963; also *A. J. P.*, 1872.)

VINUM AROMATICUM. *Aromatic Wine. Vin aromatique*, Fr. *Aromatischewein*, G. "Lavender, *one part* [or seventy-two grains]; Origanum, *one part* [or seventy-two grains]; Peppermint, *one part* [or seventy-two grains]; Rosemary, *one part* [or seventy-two grains]; Sage, *one part* [or seventy-two grains]; Wormwood, *one part* [or seventy-two grains]; Stronger White Wine, *a sufficient quantity*, To make *one hundred parts* [or one pint]. Mix the solid ingredients, and reduce them to a coarse (No. 20) powder. Moisten the powder with *four parts* [or six fluidrachms] of Stronger White Wine, pack it moderately in a conical glass percolator, and gradually pour enough Stronger White Wine upon it to make the filtered liquid weigh *one hundred parts* [or measure one pint]." *U. S.* 1880.

This preparation of the U. S. Pharmacopœia of 1880 is practically identical with the *Vin aromatique* of the French Codex, which is made by macerating one hundred parts of aromatic species (a mixture of equal parts of the herbs used in our official aromatic wine, and in addition wild thyme and hyssop) with one hundred parts of *Teinture vulnéraire* (a tincture containing the same herbs, and ten more of similar properties) and one thousand parts of red wine. This wine is principally used as an astringent and stimulating lotion to *chancres*, *open buboes*, and other *indolent ulcers*. In many cases it should be diluted, but on occasion it may be employed of full strength. It is never given internally.

VIOLA. *Violet.* The genus *Viola* (nat. ord. Violaceæ) includes numerous species, many, perhaps all, of which are possessed of analogous medical properties. *Viola tricolor*, L., the *Heart's-ease*, *Pansy*, or *Johnny-jump-up* of the gardens, was dropped from the U. S. Pharmacopœia at the late revision; whilst *V. odorata*, L., and *V. pedata*, L., formerly held places in the British or the United States Pharmacopœia.

V. odorata, L. (*Violette*, *Violette odorante*, Fr.; *Wohlriechendes veilchen*, *Veilchen*, G.; *Violetta*, It.; *Violeta*, Sp.), the common violet of Europe, resembles very closely the American blue violet, *V. cucullata*, Ait., from which, however, it is at once distinguished by its delicious fragrance. It is the sweet blue violet of our gardens. *V. pedata*, L., is an indigenous stemless violet, characterized by its large blue or variegated beardless flowers, and its deeply three- to five-divided, pointed pedate leaves.

The flowers of the *V. odorata*, L., yield their odor and their slightly bitter taste to boiling water. Their infusion affords a very delicate test for acids and alkalies, being reddened by the former and rendered green by the latter. Their odor is destroyed by desiccation; and the degree to which they retain their fine color depends upon the care used in collecting and drying them. They should be gathered before being fully blown, deprived of their calyx, and rapidly dried, either in a heated room or by exposing them to a current of very dry air. The flowers of other species are often mingled with them, and, if of the same color, are equally useful as a chemical test.

In the root, leaves, flowers, and seeds of *Viola odorata*, L., M. Boullay discovered an alkaloid, *violine*, allied to *emetine*, but possessing distinct properties. It is white, soluble in alcohol, scarcely soluble in water, and forms salts with the acids. It exists in the plant combined with malic acid. Orfila asserts that it is exceedingly active and even poisonous. It is probably found in other species of Viola. Mandelin (*Jahresbericht*, 1883) obtained a glucoside analogous to quercitrin, which he names *viola-quercitrin*. It crystallizes out of hot water in fine yellow needles. When boiled with dilute acids, it is decomposed into *quercetin* and a fermentable glucose, $C_{42}H_{42}O_{24} + 5H_2O = C_{24}H_{16}O_{11} + 3C_6H_{12}O_6$; he also obtained salicylic acid from several species of Viola. (*A. J. P.*, 1882, 10.)

The herbaceous parts of various species of violets are mucilaginous, emollient, and slightly laxative, and have been used in *pectoral*, *nephritic*, and *cutaneous diseases*. In Europe a syrup prepared from the fresh flowers of *Viola odorata*, L., is employed as an addition to demulcent drinks, and as a laxative for infants. The root, which has a bitter, nauseous, slightly acrid taste, acts in the dose of from thirty grains to a drachm (1·95–3·9 Gm.) as an emetic and cathartic. It is probable that the same property is possessed by the roots of all the violets, as it is known to be by several species of *Ionidium*, which belongs to the same natural order. The existence in small proportion of the emetic principle in the leaves and flowers accounts for their expectorant properties.

VIRGINIA CREEPER. *Ampelopsis quinquefolia*, Michx. (*Vitis quinquefolia*, Lam., also *V. hederacea*, Ehrh., and *Parthenocissus quinquefolia* (L.), Planch.) *American Ivy. Vigne vierge*, Fr. *Wilder Wein*, *Amerikanischer Ephen*, G. The bark and twigs of this indigenous woody creeper of the nat. ord. Vitaceæ have been used by the eclectics as an alterative, tonic, and expectorant. They contain tartaric acid and potassium and calcium tartrates, albumen, sugar, pyrocatechin, and some other principles. Dr. McCall employed the bark collected late in the fall in *dropsy*, with asserted very good results. (*Penins. and Independ. Med. Journ.*, June, 1858.) In two cases of poisoning reported by Mr. Bernays, the symptoms were violent vomiting and purging, collapse, and deep sleep, with dilated pupils. (*P. J. Tr.*, vii.)

VISCUM ALBUM. L *Mistletoe. Gui de Chêne*, *Gillon*, Fr. *Mistel*, G. (Nat. ord. Loranthaceæ.) A European evergreen parasitic shrub, growing on various trees, particularly the apple and other fruit trees, and forming a pendent bush from two to five feet in diameter. The plant is famous in the history of druidical superstition. In the religious rites of the Druids, the mistletoe of the oak was employed, and hence was afterwards preferred when the plant came to be used as a remedy; but it is in fact identical in all respects with those which grow upon other trees. (*P. J. Tr.*, 1897, 289.) The fresh bark and leaves have a peculiar, disagreeable odor, and a nauseous, sweetish, slightly acrid and bitterish taste. *Viscin*, which forms the glutinous constituent in the berries, leaves, and stalks of the mistletoe, is the principal constituent of *birdlime*. Crude viscin may be obtained by kneading the finely bruised mistletoe bark with water, as long as anything is dissolved, and removing the ligneous impurities mechanically. A purer product may be obtained by boiling the crude product in strong alcohol, macerating the residue with ether, evaporating the ethereal extracts, purifying these extracts by kneading first with alcohol and then with water. The formula $C_{20}H_{48}O_8(C_{20}H_{32} + 8H_2O)$ has been given to it by Reinsch. Pawlevsky (*Bull. Soc. Chim.*, (2) 34, 348) obtained from mistletoe a crystallizable acid, slightly soluble in water, in-

soluble in alcohol and ether, fusing at from 101° to 103° C., to which he gave the formula $CH_3O_3.OH$. The berries, which are white, and about the size of a pea, abound in the peculiar viscid principle, and are sometimes used in the preparation of birdlime, of which this principle is the basis. Mistletoe is said to be productive of vomiting and purging when largely taken. The berries caused in a child three years old vomiting and prostration, coma, a fixed and somewhat contracted pupil, and convulsive movements. (*Ann. de Thérap.*, 1859, 36.) A fatal case is recorded. (*Med. Times and Gaz.*, 1867, 26.) The plant was formerly looked upon as a powerful nervine, but it is now out of use. The leaves and wood were given in the dose of a drachm in substance.

The *American Mistletoe* is the *Phoradendron flavescens*, Nuttall (*Viscum flavescens*, Pursh). It is probably the plant reported as growing upon the elm, by which several children were poisoned. (Henry Dye, *Memphis Med. Recorder*, iv. 344.) The prominent symptoms were vomiting and great thirst followed by frequent discharges of bloody mucus from the bowels, with tenesmus. One of the children was found in a collapsed state, in which death took place. Dye states also that, in other instances, as he had been informed, children had eaten the *berries* without any ill effect. W. H. Long asserts (*New Prep.*, ii. 31) that the American mistletoe is a very certain oxytocic, and very efficacious in arresting post-partum and other varieties of *uterine hemorrhage*. He gives a fluidrachm (3·69 C.c.) of the fluid extract every twenty minutes in labor until the effect is produced; every four to six hours in *menorrhagia*. Dr. Lee Payne confirms this. (*North Carolina Med. Journ.*, vol. vii. 253.)

VULCANITE. For cases of poisoning by *artificial gum* made of vulcanite colored with vermilion, see *Med. Press and Circular*, Dec. 1874.

WARBURG'S TINCTURE. This famous remedy, at first a proprietary medicine, afterwards by the voluntary act of its inventor had its formula revealed. There is so much testimony as to its extraordinary virtues in the severe *remittent* and *pernicious malarial fevers* of India that its powers can scarcely be questioned. After the bowels of the patient in the acutest stage of the disorder have been freely opened, a half ounce of the tincture is given undiluted, all drink being withheld, and at the end of three hours a second half ounce is given in a similar manner. Soon after the second dose a violent, aromatic perspiration comes on, and the fever is usually broken. The remedy is also commended in *collapse* without organic disease. The formula given by Dr. Warburg is as follows. Socotrine aloes 1 lb.; rhubarb, angelica fruit, confection of Damocratis, each, ℥iv; elecampane, saffron, fennel, prepared chalk, each, ℥ij; gentian, zedoary, cubebs, myrrh, camphor, agaric, each, ℥i. Digest the whole with 500 oz. proof spirit in a water-bath for 12 hours, express, add 10 oz. sulphate of quinia, dissolve by the aid of a water-bath, cool, and filter.

It is evident that Warburg's Tincture contains various substances which are inert, but the practical difficulty is to determine as to what its extraordinary valuable anti-malarial powers are really due. The formula of Hager—quinine sulphate 1 part, spirit of camphor 2 parts, elixir proprietatis (P. G.) 22 parts, alcohol 16 parts—does not seem to us to at all represent the tincture. The formula used in the U. S. army, with asserted excellent results in Cuba, has the advantage of yielding a product in tablets, which is as follows. Aqueous extract aloes, 224 grains; rhubarb, 448 grains; angelica seed, 448 grains; elecampane, 224 grains; saffron (Spanish), 224 grains; fennel, 224 grains; gentian, 112 grains; zedoary root, 112 grains; cubeb, 112 grains; myrrh, 112 grains; white agaric, 112 grains; camphor, 112 grains; quinine sulphate, 1280 grains. Exhaust with eight pints of diluted alcohol, or divide into 1024 tablets.

The confection of Damocratis* is in the original

* The *Confection of Damocratis* (*Mithridatium*) is a combination of thirty aromatic substances, mostly obsolete, formerly official in the London Pharmacopœia. We are indebted to Robert Fletcher, of the Surgeon-General's office, for the following formula, taken from the London Pharmacopœia of 1677, p. 100. It is of course useless as a pharmaceutical preparation.

MITHRIDATIUM.

℞.
Myrrhæ Arabicæ,
Croci,
Agarici,
Zingiberis,
Cinnamomi,
Spicæ Nardi (Indian Nard or Spikenard),
Thuris (G. Olibanum),
Sem. Thlaspios, ana drachmas decem. (water-cress seeds).
Sesceleos (*Laserpitium siler*—heartwort, sermountain),
Opobalsami seu Olei Nucis Moschatæ per expressionem,
Junci odorati (Camel's hay, sweet rush, a dried plant from Turkey),
Stœchados Arabicæ (French lavender),
Costi veri (root of Costus verus or dulcis),
Galbani,
Terebinthinæ Cypriæ (Chian),
Piperis longi,
Castorei,
Succi Hypocistidos (from Cytinus, a parasitic plant in France),
Styracis Calamitæ (Gum S.),
Opopanacis,
Fol. Malabathri recentium, seu, ejus defectu, Macis, ana unciam unam.
Casiæ ligneæ veræ,
Polii montani (Teucrium creticum—Poleymountain of Candy),
Piperis albi,
Scordii (Teucrium scordium—water germander),
Sem. Dauci Cretici (Athamantis creticus—Candy carrot),
Carpobalsami vel Cubebarum (Bals. Mecca, take cubebs),
Trochisch. Cypheos,
Bdellii, ana drach. septem.
Nardi Celticæ purgatæ (Valeriana Celtica),
Gummi Arabici,
Sem. Petroselini Macedonici,
Opii,
Cardamomi minoris,
Sem. Fœniculi,
Gentianæ,
Flo. rosar. rubrarum,
Dictamni Cretensis, ana drachmas quinque.
Sem. Anisi,
Asari (A. Europæum, Asarabacca),
Acori, seu Calami Aromatici,
Ireos,
Phu majoris (Valeriana Phu, major—take ordinary Valerian),
Sagapeni, ana drachmas tres.
Mei Athamantici (Æthusa meum),
Acaciæ,
Ventrium Scincorum (Lizards),
Summitatum Hyperici, ana drachmas duas semis (Hypericum Perforatum—St. John's Wort).
Vini Canarini optimi quantum sufficit ad solutionem gummi, et succorum, nempe circiter uncias viginti-sex.
Mellis deinde despumati triplum ad omnia, præter vinum.
Fiat Electuarium secundum artem.

TROCHISCI CYPHEOS PRO MITHRIDATIO.

℞
Pulpæ Uvarum passarum pinguium, à cortice et acinis probè mundatæ.
Terebinthinæ Cypriæ,—ana uncias tres.
Myrrhæ,
Scœnanthûs, ana unciam unam et semis (Juncus odoratus).

formula in such small amount that it is hardly possible that it could have any effect. If it be omitted the formula can be very readily followed, and it seems to us that the apothecary should use the original formula with this single alteration when Warburg's Tincture is called for. (See also *Tinctura Antiperiodica*, National Formulary.)

WHITE CEDAR, OIL OF. Dr. F. K. Bailey reports the case of a girl, aged fifteen, who took sixteen drops of the oil of white cedar, and directly afterwards fell unconscious, with clonic spasms followed by epileptiform convulsions lasting at intervals for several hours. Long-continued irritation of the stomach resulted. (*N. R.*, 1872.)

WHITING. This is essentially the same as prepared chalk, being made by the pulverization and elutriation of crude chalk. It is used as a coarse paint, and for various purposes in the arts, for which calcium carbonate is requisite. *Paris white* is a variety of the same material.

WINTER'S BARK. WINTERA. The bark of *Drimys Winteri*, Forst. *Cortex Winteranus. Ecorce de Winter, Cannelle de Magellan*, Fr. *Winter's Zimmt*, G. (Nat. ord. Magnoliaceæ.) For description of tree, see *U. S. D.*, 16th ed. The tree is a native of the southern parts of South America, growing along the Strait of Magellan, and extending as far north as Chili. According to Martius, it is found also in Brazil. The bark of the tree was brought to England, in the latter part of the sixteenth century, by Captain Winter, who attended Drake in his voyage round the world, and while in the Strait had learned its aromatic and medicinal properties. Since this period, from time to time various barks have appeared in European commerce as Winter's bark, although not any that was the genuine bark. Among those in the London market was at one time the bark of *Cinnamodendron corticosum*, Miers. (nat. ord. Canellaceæ), of Jamaica, which is pungent, like true Winter's bark, but is of a much paler brown color, and resembles canella bark except in the absence of the chalky-white inner surface. Recently this bark has been replaced by the bark of *Croton malambo*, Karst. (nat. ord. Euphorbiaceæ), which resembles in color and thickness the bark of the Cinnamodendron, but has a bitter taste and a calamus-like flavor. The following is the description of a specimen which came into the possession of Dr. George B. Wood many years since. It corresponds closely with Guibourt's description of commercial Winter's bark. It is in quilled pieces, usually a foot in length and an inch or more in diameter, appearing as if scraped or rubbed on the outside, where the color is pale yellowish or reddish gray, with red elliptical spots. On the inside the color is that of cinnamon, though sometimes blackish. The pieces are sometimes flat and very large. The bark is two or three lines in thickness, hard and compact, and when broken exhibits on the exterior part of the fracture a grayish color, which insensibly passes into reddish or yellowish towards the interior. The powder resembles in color that of Peruvian bark. The odor is aromatic, the taste spicy, pungent, and even burning. P. N. Arata and F. Canzoneri describe a bark which they assert to be genuine Winter's bark from the Strait of Magellan. It was in the form of deeply furrowed, curled-up fragments with an earthy fracture, exhibiting, when in small pieces, an internal reddish-brown coloration. When fresh it had a bitter and pungent taste and an agreeable odor, recalling both turpentine and cloves. The sun-dried bark yielded: water (at 110°), 13·713 per cent.; ash, 3·338 per cent.; soluble in ether, 3·841 per cent.; in alcohol, 6·465 per cent.; in water, 13·981 per cent.; ligneous matter, 49·200 per cent. The ethereal solution contains a peculiar essence, fatty compounds, resins, and waxy matter; the alcoholic extract contains reddish uncrystallizable resins. The *Volatile Oil* was isolated by distilling the bark with water, exhausting the distillate with petroleum, and distilling off the solvent. The crude oil, amounting to 0·64 per cent. of the weight of the bark employed, is a mixture of several substances. *Winterene*, $C_{15}H_{24}$, is the essential oil separated from this by fractional distillation. It passes over between 260° and 265°; specific gravity at 13° = 0·93437. Index of refraction = 1·4931; specific rotatory power at 16° $[x] = +11·2$. It is readily oxidized on exposure to the air, becoming yellow. The formula $C_{25}H_{40}$ was calculated from the ultimate analysis and vapor density, but the authors consider that the ready oxidizability of winterene and its analogy to similar essences point rather to the formula $C_{15}H_{24}$, which would place it in the group of sesquiterpenes, such as cedrene, cubebene, etc., the boiling points of which are between 250° and 268°. (*P. J. Tr.*, June 14, 1890.) The presence of tannic acid and ferric oxide, according to M. Henry, serves to distinguish Winter's bark from *canella alba*, with which it has often been confounded. The bark above described as commercial Winter's bark is destitute both of tannic acid and ferric oxide, and cannot, therefore, be the bark examined by M. Henry.*

The bark of the *Drimys granatensis*, Linn. f. (now *D. winteri*, Forst.), has been imported into London under the name of *Merida coto*, and it has been stated that it contains cotoin. It occurs in short pieces of a yellowish-gray color, traversed longitudinally by hard cellular layers, which distinguish it at once from coto and paracoto bark. Its odor resembles that of true coto, but is more feeble. A careful chemical study of it by Dr. O. Hesse (*P. J. Tr.*, vol. lv.) shows that it contains no cotoin, but a crystalline substance, $C_{13}H_{14}O_4$, to which the name of *drimin* was given. From the leaves Hesse obtained a wax alcohol, *drimol*, $C_{28}H_{58}O_2$. As *Drimys granatensis*, L. f., is recognized as *D. winteri*, Forst., it is plain that Merida coto must be looked upon as a form of Winter's bark coming from Venezuela.

Pharmacopœia Coll. Reg. Londini, 1677, 125.

The first form of Warburg's Tincture contained a small quantity of *Mithridate;* formula therefore added.

* For Guibourt's description of true Winter's bark, written in 1850, see 17th edition *U. S. D.* Guibourt also describes the barks of two other species of Drimys, those of *D. mexicana* and *D. granatensis*, growing respectively in Mexico and Colombia, both of which have considerable resemblance to the preceding. (Tom. iii. 681, 682.)

Medical Properties and Uses. Winter's bark is a stimulant aromatic tonic, and was employed by Winter as a remedy for *scurvy*. It may be used in half-drachm doses for similar purposes with cinnamon or canella alba, but is scarcely known in the medical practice of this country. The *Drimys chilensis* of De Candolle, growing in Chili, yields a bark having similar properties (Carson, *A. J. P.*, xix. 81); also the *D. aromatica* (F. Muell.?) of Australia (*P. J. Tr.*, xxi.).

WISTARIA CHINENSIS. D. C. (Nat. ord. Leguminosæ.) Mr. Ottow (*P. J. Tr.*, Oct. 1886) has obtained from this ornamental leguminous creeper a crystalline poisonous glucoside, *wistarin*.

WOOD OIL. *Gurjun Balsam. Balsamum Dipterocarpi.* In the *P. J. Tr.* for August, 1854 (p. 65), appeared an account by Mr. Charles Lowe, of Manchester, of a "*new variety of balsam of copaiba*," derived from the East Indies. In a subsequent communication to the same journal (1856, 321) from Mr. Daniel Hanbury, it appears that this product, though offered for sale in the London market as *balsam of copaiba*, is known in India under the names of *wood oil* and *gurjun balsam*. Considerable quantities had been imported from Maulmain, in Burmah; and specimens of a similar drug had been received from Canara and Tenasserim; and it appears to be widely diffused in the Indian markets.

This liquid is obtained from *Dipterocarpus lævis*, Buch. Ham. (now *D. turbinatus*, Gaertn. f.) (nat. ord. Dipterocarpeæ), a very large gregarious tree which forms forests in Pegu and other parts of Farther India, and from other species of the genus. A large notch is cut in the trunk of the tree, between two and three feet from the ground, and a fire made so as to char the wound. The juice then begins to flow, and is received in suitable vessels. Every three or four weeks the charred surface is cut off and burned anew. A single tree sometimes yields forty gallons during the season. Other species of Dipterocarpus afford a similar product; and hence probably the difference which has been observed in the specimens examined. It is at first turbid, but may be clarified either by filtration or deposition. After filtration, wood oil is a clear, dark brown liquid, of the sp. gr. 0·964 (Hanbury), and, in consistence, smell, and taste, bears a close resemblance to copaiba. It is soluble in two parts of alcohol of the sp. gr. 0·796, with the exception of a very small proportion of darkish flocculent matter, which subsides on standing. According to Lowe, it contains 65 per cent. of volatile oil, 34 of resin, and 1 of acetic acid and water. A characteristic property noticed by Mr. Lowe, by which it may be distinguished from copaiba, is that, when heated in a closed vial to 266° F. (230° F., Lowe), it becomes slightly turbid and coagulates, so that the vial may be inverted without changing the position of its contents; and this consistence is retained when the liquid cools. By a gentle heat with agitation the fluidity returns; but the liquid again coagulates if heated to 266° F. According to D. Brandis, this property of coagulation is characteristic of the wood oil from *D. alatus*, Roxb. (*P. J. Tr.*, xxv.), a wood oil which is further to be distinguished by the greenish opalescence of its surface.

Guibourt states that wood oil does not solidify, like copaiba, with one-sixteenth of magnesia, and the two separate on standing. (*Journ. de Pharm.*, xxx. 192.) De Vrij, of Rotterdam, proposes the reaction of benzene with wood oil and copaiba respectively as a test to distinguish them. With an equal volume of the wood oil, benzene forms a turbid mixture, from which, after a long time, a resinous matter is deposited in flocculi; with copaiba it forms a transparent solution. (*P. J. Tr.*, 1857, 374.) According to De Vrij, the volatile oil obtained by distillation has the sp. gr. 0·928, and boils at 255° C. The resin left after distilling off the volatile oil is essentially *gurjunic acid*, $C_{22}H_{34}O_4$. This when purified dissolves readily in ether and strong alcohol, and slowly in benzene. It melts at 220° C. and congeals again at 180° C. Flückiger has also described a neutral resin from gurjun balsam, which is insoluble in caustic potash, fuses at 126° C., and is of the composition $C_{28}H_{46}O_2$. Flückiger (*Archiv d. Pharm.*, 1876, 420) noticed that wood oil may be recognized by the violet color it assumes if dissolved in twenty parts of carbon disulphide and mixed with a drop of a cold mixture of equal parts of concentrated sulphuric and nitric acids. A liquid is much employed in India for painting ships, houses, etc., which is also called *wood oil*; this is obtained from a different source, *Aleurites cordata* (Müller). According to Dr. O'Shaughnessy, the oil of Dipterocarpus is little inferior to copaiba in the diseases for which that medicine is employed. Dr. T. B. Henderson has found it very successful in *gonorrhœa*, given in the dose of a teaspoonful two or three times a day, uncombined. (*Med. Times and Gaz.*, 1865, 571.) It probably has a remedial influence on diseased mucous membranes similar to the different turpentines, which it appears to resemble in composition. The juice may be given in emulsion, in doses of from fifteen to forty drops (0·9–2·5 C.c.); the volatile oil from ten to thirty drops (0·6–1·9 C.c.).

East India wood oil, or gurjun balsam, must not be confounded with *Chinese wood oil* or *tung oil*, a fixed oil obtained from the euphorbiaceous *Elæococcus cordata*. This oil has a specific gravity at 60° F. of 0·94015, and does not congeal at a temperature of —8° F. If a drop of it be added to nitric acid it changes on heating into an orange-yellow solid. When a drop of sulphuric acid is brought in contact with the oil the latter apparently solidifies around the acid, forming a black envelope, which grows in size and gradually absorbs and acts upon so much of the surrounding oil as to assume the appearance of an irregular, large, dried currant. *Chinese wood oil* saponifies readily with caustic potash, two hundred and eleven parts of the caustic potash being required for a thousand parts of oil. For details, see *P. J. Tr.*, vol. xv. (See also *Proc. A. P. A.*, 1897, 677.) It is much used in China and Japan as a natural varnish for wood-work, having notable drying properties. Over 60,000 kilos are said to be sent yearly from Hankow, on the Yang-tse-Kiang, in the interior of China, to Chinese seaports.

WOORARI. *Woorara. Woorali. Urari. Curare.* This powerful South American arrow-poison was first brought to Europe by the celebrated traveller Waterton; it was in the form of a thick syrup, but as it now occurs in commerce it is a blackish extract, brittle, somewhat resinoid in appearance, encrusting the sides of gourds or little rude earthenware jars, into which it has almost certainly been poured in a liquid state. The drug varies much in strength. It has been variously described. According to the researches of Prof. Planchon (*P. J.*

Tr., xi. 491), there are really four distinct varieties of curare. 1. That from the Upper Amazon, obtained from the *Strychnos castelnœana*, Wedl, and possibly from *S. yapurensis*, G. Planch. 2. That from the Upper Orinoco, extending towards the Rio Negro, yielded by *S. gubleri*, G. Planch.; this is the variety spoken of by Humboldt. 3. That of British Guiana, obtained from *S. toxifera*,* Schomb., associated with *S. schomburgkiana*, Klotzsch (now *S. pedunculata*, Benth.), and *S. cogens*, Benth. 4. That of French Guiana, made out of *S. crevauxii*, G. Planch (now *S. crevauxiana*, Baill.). If this classification be correct, it is very important to distinguish the varieties of the woorari; this at present cannot be done. Dr. H. C. Wood has received, however, two distinct wooraris, one said to come from the Upper Amazon, therefore No. 1 of Planchon, and the other believed to come from the Orinoco. They are distinguished by the former being free from and the latter full of ants, evidently put in whilst the poison was liquid. The preparation of woorari has been witnessed by various travellers and variously described. (See *P. J. Tr.*, xvi. 502; *Brit. and For. Med.-Chir. Rev.*, Oct. 1865; *P. J. Tr.*, x., 1881.) It usually consists in making a decoction and finally extract of various plants, including the active Strychnos. Dr. Jobert asserts that the Tecuma Indians use, besides *S. castelnœana*, Baill., *Cocculus toxiferus* (?) and an arum (*Taya*), which he found to be very poisonous. According to Prof. Kobert (*Pharm. Zeitung*, June, 1885), *Malouetia nitida*, Spruce (nat. ord. Apocynaceæ), or *Guachamaca*, a plant which is abundant in the Orinoco and Rio Negro districts, enters largely into the composition of curare. The alkaloid, *guachamacine*, isolated by T. Schiffer in 1883, is very closely allied to, if it be not identical with, curarine, in both its chemical and its physiological activity. It is entirely possible that the varieties of woorari vary in their alkaloid and their physiological properties. Allied, it may be, to the third variety of woorari are the arrow-poisons brought by Dr. W. S. W. Ruschenberger from Colombia, and studied by Drs. W. A. Hammond and S. Weir Mitchell. (*Am. Journ. Med. Sci.*, July, 1859.) *Corroval* was in dark brown lumps, having the appearance of a vegetable extract, and of an intensely bitter and persistent taste. Under the microscope it presented the appearance of vegetable remains, but nothing animal. It yielded its active properties to water and alcohol, and was found to depend for its activity upon a peculiar alkaloid, *corrovaline*. In a few minutes after the introduction of the poison through a wound, paralytic phenomena became obvious, and the animal soon died, without preliminary spasm or convulsions. But the heart, instead of continuing to act after apparent death, had entirely ceased to beat, and had quite lost its irritability, so that it could not be excited by galvanism. They inferred that the action of the poison is directly and primarily on the heart, possibly through the ganglia contained in its tissue. There was no evidence whatever, either chemical or physiological, of the presence of strychnine in the poison. *Vao* or *bao* was a vegetable extract containing *corrovaline*, and apparently only a diluted or adulterated corroval. In 1893 Joseph Tillie obtained from New Granada arrows the poison on which affected chiefly the muscles, and it would seem, therefore, that under the name of woorari are used in South America arrow-poisons much more allied to strophanthus in their physiological activity than to the true wooraris, which do not attack the voluntary or involuntary muscles. To such poisons the name of *corroval* should at present be applied. The term curari has in itself no specific meaning, since, according to Dr. Whiteford, it is simply the Indian word for *poison*. It is plain that the poisons coming from South America under the name of woorari are various, although in appearance the same, and that at present, therefore, woorari can hardly be used in practical medicine.

The attempts first made to isolate the poisonous principle of woorari were without satisfactory results. Dr. Heintz succeeded in obtaining the poison in an exceedingly concentrated form, but not entirely separated from other principles. (*Am. Med. Gaz.*, vii. 6.) In 1828 MM. Boussingault and Roulin separated a substance which they regarded as an alkaloid, but which neither they nor other chemists obtained in a crystalline state. Pure concentrated sulphuric acid gives with the curare alkaloids a very durable, magnificent blue color, which is not the case with strychnine. With potassium bichromate the same acid develops the same violet color as with strychnine, but much more persistent. Concentrated nitric acid renders it purple. By these tests curare may be readily detected in the fluids of animals poisoned with it. (*Journ. de Pharm.*, 4e sér., ii. 296.) Within the last few years R. Boehm has finally isolated the two bases, *curarine* (also called *tubo-curarine* from its source in the curare packed in bamboo tubes), $C_{19}H_{21}NO_4$, and *curine*, $C_{18}H_{19}NO_3$. The free tubo-curarine forms an amorphous brown-red mass. Boehm (*Berichte*, xx. 143) states that curine exists in many specimens of curare; it may also be obtained from the aqueous extract of curare. It is much less poisonous than the accompanying curarine. Curine is a crystalline powder fusing at 161° C., slightly soluble in cold water, freely in alcohol, chloroform, and dilute acids. It forms a voluminous white precipitate with metaphosphoric acid.

Woorari is one of those poisons whose active principle passes through animal membranes with difficulty, and hence when given by the stomach or rectum it acts very slowly, and in some cases elimination may proceed so rapidly that no marked influence is exerted, because not enough of the alkaloid is in the blood at any one time. There is also some reason for believing that the alkaloid is destroyed in the liver. When injected into a vein, or introduced by the hypodermic needle or the poisoned arrow into the cellular tissue, it acts with great promptness. The symptoms caused are progressive loss of muscular power, the animal growing weaker and weaker, the respirations becoming more and more feeble, until death by asphyxia results. Not rarely there are marked muscular twitchings, or even convulsive movements, which Vulpian asserts (*Leçons Subs. Toxiq.*, 1881, 202) are not due to the asphyxia, because they are not prevented by artificial respiration. They are probably of centric origin, since Tillie (*Arch. Exper. Path. Pharm.*, xxvii.) has shown that the drug first excites the spinal cord, although such action is masked by the paralysis of the motor nerves. The heart usually

* The bark of the *Strychnos toxifera* has been chemically examined by Mr. Villiers, who finds that its purified extract resembles in its chemical and physiological relations ordinary curarine. He was not able, however, to obtain the pure alkaloid. (*Journ. de Pharm. et de Chim.*, fifth series, vol. xi.)

continues beating after cessation of breathing, and only very large doses of the poison affect early the arterial pressure. It has indeed very little action upon the cardiac or vaso-motor apparatus unless the dose be very large, when the blood-pressure sinks from depression of the peripheral vaso-motor nerves (Tillie); the cardiac fibres of the vagi also suffer (Dogiel and Nikolski). The failure of muscular power and loss of reflex activity are not due to any influence upon the nerve-centres or the muscles, but to paralysis of the motor nerves: it is probable, as Vulpian believes, that it is the extreme peripheral endings of these which first suffer. At a certain stage of the poisoning, response occurs in the tributary muscle when a nerve is galvanized, although reflex and voluntary impulses are unable to force a passage to the muscles. The sensory, vaso-motor, and inhibitory nerves are not affected unless by enormous doses. Couty and De Lacuda have recently brought forward some evidence to show that the muscles do not escape as absolutely as has been believed. (*Schwalbe's Jahresb.*, 1881, 203.) Death has generally been attributed to paralysis of the respiratory nerves, but Dogiel and Nikolski affirm that the respiratory centres are paralyzed.

Glycosuria has very often been noticed, and the curarine has frequently been detected in the urine, which also usually contains an abundance of crystals of calcium oxalate. In regard to action upon the bodily temperature the evidence is somewhat contradictory. Bernard noticed an extraordinary rise, but, according to more recent observations, the temperature of the central portions of the body falls, whilst that of the extremities, and sometimes even of the lower rectum, rises. MM. Voisin and Liouville divide the effects on the human subject into two classes, according to their severity. The milder symptoms are chiefly exhibited in the circulatory system. The pulse is increased in force and frequency, the respiration is rendered somewhat more frequent, the temperature is slightly elevated, perspirations sometimes occur, and the urine is augmented in quantity, is remarkably light-colored, and contains glucose. From larger quantities of the poison violent febrile phenomena occur, commencing with the characteristic symptoms of a severe chill. There are shivering, chattering of the teeth, sensations of severe cold, cutis anserina, startings, and general trembling, with small and rapid pulse, anxiety, sighing, etc. The power of the lower extremities rapidly diminishes or quite ceases, co-ordination of motion is disturbed, and sometimes the patient is unable to move the legs. Thirst, headache, insomnia, and sometimes diuresis, are added to the other symptoms. The first coldness is followed by a hot skin, frequent and full pulse, redness of the surface, injected conjunctiva, and a profuse sweat. The paralysis of the lower extremities continues generally for a few minutes, at most for an hour; but care was taken to arrest the action of the poison by compressing the vessels above the point of insertion. The fever continues longer; sometimes, when the dose is large, for five or six days, gradually diminishing. The elimination of the poison by the kidneys appears to cease in about twenty-four hours. In cases of poisoning from the injection of woorari, a ligature round the limb between the place of injection and the heart, the free exhibition of diluents and evacuants, and artificial respiration when required, are the measures recommended. (*Ed. Med. Journ.*, 1867, 667.)

As a remedy curare has very little value, even in *tetanus*, *hydrophobia*, and other severe *convulsive affections;* it will undoubtedly quiet the spasm, but does not have any direct curative influence upon the disease, which is due to an irritation of the centres and not of the nerve-trunks. According to the elaborate experiments of M. Du Cazal (*Arch. Gén.*, Sept. 1869), from one-fourteenth to one-seventh of a grain (0·005–0·01 Gm.) daily were borne by a dog without inconvenience; at the dose of ten milligrammes the characteristic phenomena began to show themselves, but disappeared in a few hours; with fourteen milligrammes the animal perished. For man the doses administered by subcutaneous injection were from one-sixth to three-fourths of a grain (0·01–0·05 Gm.). From these quantities, the appearance of glucose in the urine proved the presence of the poison in the system, and some slight characteristic symptoms, as dizziness, headache, vertigo, general lassitude, have appeared, but without any serious disturbance of the locomotor apparatus. MM. Jousset and Bellesme prepare an infusion in the proportion of one part of the medicine to ten parts of boiling water, and, after filtration, inject subcutaneously, at short intervals, a quantity of the infusion equivalent to a half a centigramme (about one-thirteenth of a grain), to be increased or diminished according to its effects. (*Ann. de Thérap.*, 1866, 37.) According to Bernard, *curarine* is at least twenty times as strong as curare, and should be given in proportionate dose. According to the experiments of Dr. Joseph Tillie, *curine* has no influence upon the motor nerves, but acts both in the frog and in the mammal upon the heart, belonging physiologically to the digitalis group. Prof. Boehm states that the presence of curine in curare can be recognized by the white precipitate made by metaphosphoric acid.

WRIGHTIA ANTIDYSENTERICA. R. Br. (*Nerium Antidysentericum*, L., now *Wrightia zeylanica*, R. Br.) (Nat. ord. Apocynaceæ.) Under the names of *Conessi bark*, *Tellicherri bark*, and *Codaga pala*, a spongy, rusty-colored, bitter bark of this apocynaceous tree was formerly used in Europe as a remedy in *dysentery* and *diarrhœa*, and is said still to be largely employed by the native practitioners of India. Dr. Stenhouse obtained from the seeds, besides a fixed oil which they contain in large quantity, a peculiar bitter principle, called by him *wrightine*, which, though uncrystallizable, and forming uncrystallizable compounds with the acids, has claims to be ranked with the alkaloids. (See *P. J. Tr.*, 1864, 493.) Hains had previously obtained the same alkaloid, and described it under the name of *conessine*. (*P. J. Tr.*, (2) vi. 432.) The alkaloid conessine is now a commercial product prepared by Merck, and a formula, $C_{12}H_{20}N$, is given it. It occurs in delicate white interlaced masses of crystals, melting at 121° C., sparingly soluble in water, readily so in alcohol. A small quantity rubbed with a few drops of concentrated sulphuric acid affords on the addition of nitric acid a golden- and finally orange-yellow color. We are not aware that the medical properties of this have been investigated.

A species of the genus, *Holarrhena africana*, A. D. C., is stated by the German missionaries to be used in tropical Africa in *dysentery*. Polstorff and Schirmer (*Ber. der Chem. Ges.*, 1886, 78) prepared the alkaloid both from *Holarrhena africana* and from *Wrightia antidysenterica*, finding it to be

identical in the two cases. They give it the formula $C_{12}H_{20}N$, and state that it is a light white powder, melting at 121·5° C., sparingly soluble in water, freely soluble in alcohol, ether, chloroform, and benzene. When oxidized by iodic acid in sulphuric acid solution, conessine is changed to *oxyconessine*, $C_{12}H_{20}NO$.

XANTHIUM. M. Guichard believes that he has found an alkaloid in the *X. speciosum*. (*P. J. Tr.*, vii. 249.) In the *Xanthium strumarium*, *Cocklebur* or *Clotbur*, which is common both in Europe and in America, A. Zander believes that he has found a glucoside, *xanthostrumarin*. M. V. Cheatham thinks that there is a second active principle. (See *A. J. P.*, vol. xi. 271, vol. xiv. 134.) Clotbur is stated to be an active styptic, both local and general. Dose of fluid extract, from one to two fluidrachms (3·7–7·4 C.c.).

XANTHORRHIZA. *Yellow-root. Xanthorrhiza apiifolia.* L'Herit. (*X. tinctoria.* Woodhouse.) This is a ranunculaceous shrub, two or three feet in height, with a horizontal root, which sends off numerous suckers. The stem is simple, rather thicker than a goose-quill, with a smooth bark and bright yellow wood. The leaves, which stand thickly at the upper part of the stem, are compound, consisting of several ovate-lanceolate, acute, doubly serrate leaflets, sessile upon a long petiole, which embraces the stem at its base. The flowers are small, purple, and disposed in long, drooping, divided racemes, placed immediately below the first leaves. The yellow-root grows in the interior of the Southern and in the Western States. Nuttall says that it is abundant on the banks of the Ohio. It flowers in April. The root was formerly in the Secondary List of the U. S. Pharmacopœia; but the bark of the stem possesses the same virtues. The root is from three inches to a foot or more in length, and about half an inch in thickness near the stem. It shrinks somewhat in drying, and, as found in the shops, is in slender pieces of various lengths, diminishing from three or four lines in thickness to the dimensions of a knitting-needle, wrinkled longitudinally, with a light yellowish-brown, easily separable epidermis, a thick, hard, bright yellow woody portion, and a very slender central pith. It is inodorous, and of a simple but extremely bitter taste. It imparts its color and taste to water. The infusion is not affected by a solution of ferrous sulphate. Dr. J. Dyson Perrins has found *berberine* in it. (*P. J. Tr.*, May, 1862.) Mr. Samuel S. Jones believes that he has proved the existence in the drug of a second alkaloid. (*A. J. P.*, vol. xvi. 161.) Xanthorrhiza possesses properties closely analogous to those of calumba, quassia, and other simple tonic bitters, and may be used for the same purposes and in the same manner. Dr. Woodhouse employed it in the dose of two scruples (2·6 Gm.).

XANTHORRHŒA RESINS. *Gum Acaroides. Gum Acroides.* Yellow and reddish resinous substances, the products of different species of Xanthorrhœa (nat. ord. Juncaceæ), have been introduced into England from Australia. They are obtained by spontaneous exudation from the stems of the plants, which are usually shrubs. The *yellow variety* (from *Xanthorrhœa hastilis*, Sm.; syn. *X. resinosa*, Sm., now *X. media*, R. Br.) is in tears, in flattish pieces having on one side the mark of the stem, or in masses of various size and irregular shape. It has a reddish-yellow color, resembling gamboge when broken, and when heated emits a fragrant odor like that of Tolu balsam. It contains resin, cinnamic and benzoic acids, and a trace of volatile oil, and may therefore be ranked among the balsams. When heated with nitric acid, it yields a large product of picric acid. In medical properties it is said to bear a close resemblance to storax and the balsam of Tolu. A tincture, made in the proportion of two ounces to a pint of alcohol, may be given in the dose of one or two fluidrachms. The *red variety* (from *Xanthorrhœa australis*, R. Br.) resembles dragon's blood in color, and appears to be analogous to the other variety in properties. (See *A. J. P.*, 1881; also *A. J. P.*, vol. xv., and *Drug. Circ.*, 1895, 83.) These resins have been introduced as a shellac substitute in varnish-making.

XYLENE. *Xylol. Xylène*, Fr. *Xylol*, G. $C_6H_4(CH_3)_2$. There are three isomeric hydrocarbons of this name, the ortho-, meta-, and paraxylene respectively, all contained in coal tar. A mixture of them was first extracted from naphtha by Dr. Hugo Müller, and was brought forward by Dr. Zuelzer as a specific in *small-pox*, but is useless. (*P. J. Tr.*, 1872, 623.)

YLANG YLANG OIL. *Cananga Oil. Oleum Anonæ. Oleum Unonæ.* This is a volatile oil obtained from the flowers of *Cananga odorata*, Hook. f. and Thoms (nat. ord. Anonaceæ), a large tree inhabiting most parts of Southern Asia. According to Schimmel & Co. (*Semi-annual Report*, April, 1897), it contains pinene, linalool, geraniol esters of acetic and benzoic acids, cadinene, and paracresol-methyl ester. It is used only as a perfume. (See *N. R.*, April, 1881.) The so-called *Macassar Hair Oil* is said to be a solution of it in cocoanut oil. (See *A. J. P.*, 1881, 123; also *A. J. P.*, 1893, 529.)

ZEDOARY. *Radix Zedoariæ. Rhizoma Zedoariæ*, P. G. *Zedoaire*, Fr. *Zitterwurzel*, G. There are two kinds of zedoary, the long and the round, distinguished by the old official titles of *radix zedoariæ longæ* and *radix zedoariæ rotundæ*; the former produced by the *Curcuma zedoaria*, Roxb. (now *Z. aromatica*, Salisb.), the latter, as some suppose, by the *Kæmpferia rotunda*, L., but, according to others, by the *Curcuma zerumbet*, Roxb. (now *C. Zedoaria*, Rosc.), all of the nat. ord. Scitamineæ. Both kinds come from the East Indies. The *long zedoary* is in slices, from an inch and a half to three inches in length, and from half an inch to an inch thick, obtuse at the extremities, and exhibiting the remains of the radical fibres. The *round* is also usually in slices, which are the sections of a roundish root, ending in a point beneath, and divided longitudinally into two parts, each of which is flat on one side, convex on the other, and heart-shaped in its outline. Sometimes the root of the latter variety is entire, and sometimes in quarters instead of halves. It is marked with circular rings on the convex surface, and, like the former, with small projecting points which are the remains of radical fibres. Both are grayish white on the outside, yellowish brown within, hard, compact, of an agreeable aromatic odor, and a bitterish, pungent, camphorous taste. The round, however, is less spicy than the long. They yield a volatile oil, when distilled with water, and contain a pungent soft resin and bitter extractive. Zedoary is a warm, stimulating aromatic, useful in flatulent colic and debility of the digestive organs. It is not now employed, as it produces no effects which can-

not be as well or better obtained from ginger. The dose is from ten grains to half a drachm (0·648–1·94 Gm.).

ZERECHTIT. *Tschuking.* The leaves, flowers, and fruit of an Abyssinian composite, *Ubiæa schimperi*, J. Gay (now *Landtia schimperi*, Benth. and Hook.). (See *Proc. A. P. A.*, xxvi. 228.)

ZERUMBET. *Cassumuniar.* Under these names an East India root was formerly used, having some analogy in sensible and medical properties to ginger, and ascribed to the *Zingiber zerumbet* of Roscoe. Some consider the cassumuniar as a distinct root, and refer it to the *Zingiber cassumunar* of Roxburgh. The difference of opinion is of little importance, as neither of the roots is to be found in the markets. By some authors the zerumbet has been erroneously confounded with the round zedoary. Geiger describes it as in pieces of the size of a fig or larger, externally grayish brown and wrinkled, internally yellowish, hard and tough, of a biting, aromatic taste, and a spicy odor.

ZINC BORATE. *Zinci Boras.* $ZnB_4O_7 + 7H_2O$. Prepared by mixing an aqueous solution of zinc sulphate (1 in 10) with one of borax (1 in 25), and collecting the precipitate. Used as an antiseptic dusting powder.

ZINC CYANIDE. *Zinci Cyanidum. Cyanuret of Zinc.* $ZnCy_2$. This cyanide is precipitated as a white insoluble powder, by adding cautiously, until it ceases to produce a precipitate, a recently filtered solution of potassium cyanide to a solution of zinc sulphate. It is used in Germany as a substitute for hydrocyanic acid, and is said to be anthelmintic. It has been recommended by Dr. Lashkevich in cardiac neuroses in doses of from one-tenth to one-eighth grain (0·006–0·008 Gm.) three times a day. It has been employed in *epilepsy*, *chorea*, and *neuralgia*, in several *painful affections of the stomach*, and in the *colics* attendant on *difficult menstruation*. The dose is a quarter of a grain (0·016 Gm.), gradually increased to a grain and a half (0·097 Gm.), given in mixture. It is official in the French Codex.

ZINC FERROCYANIDE. *Zinci Ferrocyanidum. Ferrocyanuret of Zinc.* $Zn_2FeCy_6 + 3H_2O$. Formed by double decomposition between hot solutions of potassium ferrocyanide and zinc sulphate. It is thrown down as a white powder. It has similar medical properties to those of the cyanide, and is used in the same diseases. The dose is from one to four grains (0·06–0·25 Gm.), given in pill. (See *Zinc Cyanide.*)

ZINC LACTATE. *Zinci Lactas. Lactas Zincicus. Zincum Lacticum.* $Zn(C_3H_5O_3)_2 3H_2O$. This salt is used by M. Herpin in doses of two grains (0·13 Gm.), three times a day, gradually increased to ten grains (0·65 Gm.) a day, as a substitute for zinc oxide in *epilepsy*. For its physical properties and methods of preparation, see 16th ed. *U. S. D.*

ZINC PHOSPHATE. *Zinci Phosphas.* $Zn_3P_2O_8, 2H_2O$. Dr. Barnes, of London, has brought forward this salt of zinc as having special advantages over other salts of the same metal in the treatment of *nervous diseases*, peculiarly useful in the *insanity* occurring in the convalescence from fevers, in which he associates it with quinine, and in *epilepsy* attended by *disorder of the uterine functions*. Zinc phosphate, or *trizincic orthophosphate*, may be prepared by the mutual reaction of zinc sulphate and an alkaline phosphate. It is a white powder, insoluble in water but soluble in acids.

ZINC SUBGALLATE. *Zinci Subgallas.* An odorless powder containing 44 per cent. of zinc oxide and 56 per cent. of gallic acid. Internally it is used in intestinal disorders as an antiferment in doses of from one-half to four grains (0·033–0·25 Gm.). Externally it has been used in skin diseases.

ZIZYPHUS VULGARIS. Lamarck. (Now *Z. sativa*, Gaertn.) *Jujube*, Fr. *Brustbeeren, Judendornbeeren*, G. A shrub, or small tree, of the nat. ord. Rhamnaceæ, growing on the shores of the Mediterranean, and cultivated in Italy, Spain, and the south of France. The fruit is the part used. This consists of oval drupes, of the size of a large olive, with a thin, coriaceous, red or reddish-brown skin, a yellowish, sweet, acidulous pulp, and an oblong, pointed stone in the centre. These have the official name of *jujubæ*. By drying, their pulp becomes softer and sweeter, and acquires a vinous taste, evincing the commencement of fermentation. They are nutritive and demulcent, and are used in the form of decoction in *pectoral complaints*. *Jujube paste* consists properly of gum arabic and sugar, dissolved in a decoction of this fruit, and ovaporated to the proper consistence. As a demulcent it is in no respect superior to a paste made with gum arabic and sugar alone, and the preparation formerly sold in this country under the name contains in fact none of the fruit. The fruits of two other species, *Z. lotus* (Lam. ?), growing in the north of Africa, and *Z. jujuba*, Lam., a native of the East Indies, possess properties similar to those of the *Z. vulgaris*, and are used as food by the inhabitants of the countries where they grow. The *Zizyphus jujuba*, Lam., is stated by Bosisto (*A. J. P.*, 1886) to be one of the main sources of stick-lac, from which shellac is manufactured.

ZYGADENUS. This is a liliaceous genus, widely represented in the United States, some members of which are believed to be poisonous. Dr. H. S. Goodell affirms that he has seen violent convulsions produced by the juice of *Z. venenosus*, Watson. According to Watson, among the northern tribes of Indians the bulb of this species is said to be very poisonous, and is known as the *Death Camass*.

ZYMOIDIN. A powder said to be composed of zinc oxide, bismuth oxide, aluminum oxide, iodine, boric acid, carbolic acid, gallic acid, salicylic acid, quinine, and other ingredients. It is used as an antiseptic and dusting powder.

PART III.

In this division are included the subjects formerly embraced in the Appendix of this work, with the addition of the official tests and various tables, many of which are introduced for the first time in the Dispensatory.

TESTS.

LIST OF REAGENTS. U. S. 1890.

The constant reference to tests in the previous pages, and the adoption of volumetric test-solutions in the U. S. Pharmacopœias of 1880 and 1890, and the British Pharmacopœia (1898), necessitate the insertion of the official reagents and solutions used in the quantitative and qualitative tests. Great care should be used, in preparing these tests and selecting the reagents, to see that they come fully up to the official requirements, as the whole value of the test depends upon the purity of the reagent and the accuracy with which the solution has been made.

I. PRELIMINARY REMARKS.

Official Substances as Reagents.—Some official substances (chemicals, chemical solutions, etc.) are sufficiently pure to be used as reagents, if they comply with the tests of purity prescribed by the Pharmacopœia. In the case of others, the presence of certain impurities, though immaterial for their use as medicines, renders their employment as reagents unsuitable. Whenever a greater degree of purity is required than is provided for by the text of the Pharmacopœia, it will be specially mentioned in the following lists.

Abbreviations and Signs Used:

T.S. = Test-solution.

V.S. = Volumetric solution.

$\frac{N}{1}$ = Normal (see under "Volumetric Solutions" in List III.).

$\frac{N}{2}$ = Seminormal; $\frac{N}{10}$ = Decinormal; $\frac{N}{100}$ = Centinormal.

$\frac{2}{N}$ = Double-normal (sometimes written: 2 N).

★ (asterisk) *in front* of a figure denotes that the quantity or value expressed by the figure is approximate. In the case of a volumetric solution, for instance, ★25 C.c. means "about 25 C.c.," and this is to be interpreted as standing for "24·5 to 25·5 C.c.," the allowable variation in such cases being 2 per cent. either way. In the text of the Pharmacopœia this is expressed by saying "about 25 C.c.," or "about 16 per cent. of iron," etc.

Keeping of Reagents.—Reagents should be kept in bottles made of glass free from lead and arsenic, and proof against corrosion by acids and alkalies, preferably in those made of Bohemian glass.

The bottles should be closed by well-ground glass stoppers. Stoppers of bottles containing alkali hydrates, ammonium sulphide, ammonia water, tannic acid, and other substances rapidly attacking ground glass surfaces, should be lubricated with a thin film of petrolatum.

Reagents easily affected by light, such as hydrogen sulphide T.S., ammonium sulphide T.S., chlorine water, etc., should be kept in bottles made of dark amber-colored glass.

Note.—As some of the following test-solutions are in certain cases directed in definite quantities in lieu of the regular volumetric solutions, it is important that they should always be prepared of the *exact strength prescribed.*

II. LIST OF REAGENTS AND TEST-SOLUTIONS.

Note.—The reagents are arranged in alphabetical order. The test-solutions are usually mentioned in connection with the principal chemical or other substance from which they are prepared. The volumetric solutions will be found in List III. (Nos. 117–135).

Whenever *water* is required or mentioned as a solvent in the tests given in the Pharmacopœia, or in the preparation of any reagent, it is understood that *distilled water* shall be used.

1. **Absolute Alcohol** (Ethyl Alcohol), $C_2H_5OH = 45{\cdot}9$.—Use the official absolute alcohol [*Alcohol Absolutum*].

2. **Acetic Acid**, $HC_2H_3O_2 = 59{\cdot}86$.—Use the official acetic acid [*Acidum Aceticum*].

3. **Albumen Test-Solution.**—Carefully separate the white of a hen's egg from the yolk, shake it thoroughly with 100 C.c. of water, and filter. This solution should be freshly made when required.

4. **Aluminum.**—Metallic aluminum, $Al = 27{\cdot}04$, in the form of foil, wire, or ribbon. It should be tested for arsenic by Fleitmann's method (see below, No. 13), when no color should be imparted to the silver nitrate within two hours.

5. **Ammonia Water**, $NH_3 = 17.01$.—Use the official ammonia water [*Aqua Ammoniæ*].

6. **Ammonium Carbonate Test-Solution.**—Dissolve 10 Gm. of ammonium carbonate, NH_4HCO_3-$NH_4NH_2CO_2 = 156{\cdot}77$ [*Ammonii Carbonas*, U. S. P.], in a mixture of 10 C.c. of ammonia water and 40 C.c. of water.

For detecting arsenic sulphide in presence of antimony sulphide, the addition of ammonia water is omitted, and 10 Gm. of the salt are dissolved in a sufficient quantity of water to make 100 C.c.

7. **Ammonium Chloride Test-Solution.**—Dissolve 10 Gm. of ammonium chloride, $NH_4Cl = 53{\cdot}38$ [*Ammonii Chloridum*, U. S. P.], in enough water to make 100 C.c.

8. **Ammonium Molybdate Test-Solution.**—Dissolve 1 Gm. of finely powdered ammonium molybdate, $(NH_4)_2MoO_4 = 195{\cdot}76$, in 6·7 C.c. of hot water, using a little ammonia water, if necessary, to effect solution. Then gradually pour the liquid into a mixture of 3·3 C.c. of nitric acid (spec. grav. 1·414) and 3·4 C.c. of water. Preserve the test-solution in the dark, and, if a sediment should form in it after some days, carefully decant the clear solution from it.

9. **Ammonium Oxalate Test-Solution.**—Dissolve 4 Gm. of pure, crystallized ammonium oxalate, $(NH_4)_2C_2O_4 + H_2O = 141{\cdot}76$, free from metals, chloride, and sulphate, in enough water to make 100 C.c. Or, dissolve 4 Gm. of pure oxalic acid (see below, No. 121) in 100 C.c. of water, add 20 C.c. of ammonia water, boil to expel excess of ammonia, and bring the volume to 113 C.c.

On evaporating a portion of the test-solution, and igniting the residue, it should be completely volatilized (absence of *fixed impurities*).

10. **Ammonium Phosphate Test-Solution.**—Dissolve 1 Gm. of ammonium phosphate, $(NH_4)_2$-$HPO_4 = 131{\cdot}82$, together with 2 C.c. of ammonia water, in enough water to make 100 C.c. This solution does not keep well. It should be freshly made when required, or frequently renewed.

10*b*. **Ammonium Sulphate.**—$(NH_4)_2SO_4 = 131{\cdot}84$.—The purified salt, leaving no residue upon ignition.

11. **Ammonium Sulphide Test-Solution.**—Saturate 3 parts of pure ammonia water with pure, washed hydrogen sulphide, and add to the solution (which now contains ammonium sulphhydrate, $NH_4HS = 50{\cdot}99$) 2 parts of ammonia water, which converts the greater portion of the ammonium sulphhydrate into ammonium sulphide $(NH_4)_2S = 68{\cdot}0$. The solution should be perfectly clear and colorless, and, on being evaporated, leave no residue. It should not be rendered turbid either by magnesium sulphate T.S. (absence of *free ammonia*), or by calcium chloride T.S. (absence of *ammonium carbonate*). It should be protected against air and light by being kept in small, dark amber-colored bottles, in a dark place. As soon as a notable deposit of sulphur has made its appearance in the solution, it should be rejected.

Ammonium polysulphide test-solution is occasionally required. This is a yellow liquid, prepared by dissolving a small quantity of pure sulphur in the preceding, colorless ammonium sulphide test-solution.

12. **Arsenic Test, Bettendorff's.**—To a small quantity of the liquid to be tested, which should contain much pure concentrated hydrochloric acid, or should be a solution of the substance to be tested in pure, concentrated hydrochloric acid, add an equal volume of a saturated solution of freshly prepared stannous chloride in pure, concentrated hydrochloric acid, together with a small piece of pure tin-foil. The presence of arsenic is revealed by the production of a brown color or brown precipitate, the appearance of which is hastened by a gentle heat (see Stannous Chloride, No. 108).

13. **Arsenic Test, Fleitmann's.**—Into a test-tube of at least 15 Cm. in length, and 15 to 18 Mm. in diameter, place a single, solid piece of zinc (see below, No. 115), weighing about 1 to 1·25 Gm., and add about 5 C.c. of potassium hydrate T.S. [*Liquor Potassæ*, U. S. P.], both ingredients having previously been proven free from arsenic by having been subjected, *alone*, to the test about to be described, during at least two hours, with negative result. Now add the liquid to be tested, which must not contain any free acid, nor very materially increase the volume of the contents of the test-tube. Immediately secure over the mouth of the test-tube a previously prepared cap made of three thicknesses of pure filter paper free from dust, and apply to the upper filter paper a drop of a saturated, aqueous solution of silver nitrate acidulated with nitric acid (see Silver Nitrate T.S., No. 96). Then place the tube at once, upright, into a box containing sand heated to about 90° C. (194° F.), and fitted with a cover, so as to exclude light and dust, and permit the reaction to proceed for such a time as may be specially prescribed in each case. The presence of arsenic (but not of antimony) is revealed by the production, upon the moistened paper cap, of a brown or black stain. In absence of arsenic, if the test has been carefully conducted, the spot will remain colorless.

In place of zinc, metallic aluminum, best in form of wire, cut into small pieces, may be employed (*Gatehouse's* modification). The method of testing, and the results, are the same as in Fleitmann's test.

14. **Arsenic Test, Gutzeit's.**—Into a test-tube of at least 15 Cm. in length, and 15 to 18 Mm. in diameter, place a single, solid piece of zinc (see below, No. 115), weighing about 1 to 1·25 Gm., and add

about 5 C.c. of a mixture, previously prepared and kept in readiness for this purpose, of 10 C.c. of pure sulphuric acid of spec. grav. 1·835, and 190 C.c. of water, the ingredients having previously been proven free from arsenic by having been subjected, *alone*, to the test about to be described, during at least two hours, with negative result. Now add the liquid to be tested, which should not be alkaline, nor exceed 1 C.c. About 1 Cm. below the open end of the test-tube insert a loose plug, about 1 Cm. long, of glass-wool or cotton, which has been moistened with 0·5 C c. of lead acetate T.S. Then secure over the mouth a cap made of three thicknesses of clean filter paper, and apply to the upper one a drop of a saturated, aqueous solution of silver nitrate, acidulated with nitric acid (see Silver Nitrate T.S., No. 96). Place the tube into a box to exclude light, and let the reaction proceed as long as may be prescribed in each case. The presence of arsenic is shown by the production, upon the moistened paper cap, of a bright yellow stain which becomes black or brown by application of water. Antimony colors the spot black or brown at once without showing a yellow color while dry. In this case, traces of arsenic may be overlooked; it is therefore advisable to subject a fresh portion of the specimen to Fleitmann's test (see No. 13), which responds only to arsenic. If the plug moistened with lead acetate T.S. be strongly colored, so that doubt exists whether the coloration be due to metallic silver reduced by arsenic, or to silver sulphide, produced by an escape of H_2S through the plug, moisten the silver stain with diluted nitric acid, which will dissolve the metallic silver reduced by arsenic, but will not affect the black silver sulphide. Or else, put on a new cap of filtering paper, moistened with a drop of lead acetate T.S. If this remain colorless, sulphide is absent.

15. **Barium Carbonate.**—Pure barium carbonate, $BaCO_3 = 196·75$, prepared by dissolving 12 parts of pure, crystallized barium chloride in 20 parts of boiling water, then adding a solution of 5 parts of ammonium carbonate in 10 parts of boiling water, and afterwards 5 parts of ammonia water; finally washing the precipitate thoroughly and drying it.

16. **Barium Chloride Test-Solution.**—Prepared from pure barium chloride, $BaCl_2 + 2H_2O = 243·56$. The aqueous solution of the salt should be perfectly neutral, and should not yield a precipitate with hydrogen sulphide T.S. or ammonium sulphide T.S. (absence of *metals*, etc.). The aqueous solution, after being precipitated by diluted sulphuric acid in slight excess, yields a filtrate which should not leave any permanent residue when evaporated and heated on platinum-foil (absence of *other fixed bases* and *salts*). Diluted alcohol, after remaining in contact with it for several hours, should, upon ignition, show a pure yellowish-green colored flame, without red streaks (absence of *traces of strontium*). To prepare the *test-solution*, dissolve 12·2 Gm. of the salt in enough water to make 100 C.c. (This solution is of normal strength $= \frac{N}{1}$ V.S., so as to permit of its use for volumetric purposes also.)

17. **Barium Hydrate Test-Solution.**—A saturated solution of barium hydrate [barium hydroxide, $Ba(OH)_2 = 170·82$] in water. This solution rapidly absorbs carbon dioxide from the air. It is preferably prepared freshly as wanted.

18. **Barium Nitrate Test-Solution.**—Prepared from pure barium nitrate, $Ba(NO_3)_2 = 260·68$. This salt should respond to the same tests as barium chloride (see No. 16). In addition, its aqueous solution, slightly acidulated with nitric acid, should not be rendered turbid by silver nitrate T.S. (absence of *chloride*). To prepare the *test-solution*, dissolve 1 Gm. of the salt in water to make 15·3 C.c. (This solution is of half normal strength $= \frac{N}{2}$ V.S., so as to permit of its use for volumetric purposes also.)

19. **Benzin, or Petroleum Ether.**—Use the official benzin [*Benzinum*].

20. **Benzol, or Benzene.**—Benzol, $C_6H_6 = 77·82$, is a colorless, transparent liquid of a peculiar, aromatic odor, of a spec. grav. of 0·8846 at 15° C. (59° F.), congealing at 0° C. (32° F.), and boiling at 80·37° C. (176·7° F.). It is insoluble in water, but soluble in 4 parts of alcohol, and in ether. In concentrated sulphuric acid it should dissolve without producing a color. On shaking 2 C.c. of benzol with 0·5 C.c. of sulphuric acid and 1 drop of fuming nitric acid, no green or blue tint should be produced (absence of *thiophene*).

21. **Brazil Wood Test-Solution.**—See under *Indicators* (No. 49).

22. **Bromine Water** (Bromine Test-Solution), Br. = 79·76.—An aqueous solution of bromine [*Bromum*, U. S. P.], prepared by dissolving 1 C.c. of bromine in enough water to make 100 C.c.

23. **Calcium Chloride Test-Solution.**—Dissolve 10·925 Gm. of crystallized calcium chloride, $CaCl_2 + 6H_2O = 218·41$, in enough water to make 100 C.c. (This solution is of normal strength $= \frac{N}{1}$ V.S., so as to permit of its use for volumetric purposes also.)

24. **Calcium Hydrate Test-Solution** (Lime Water), $Ca(OH)_2 = 73·83$.—Use the official lime water [*Liquor Calcis*].

25. **Calcium Sulphate Test-Solution.**—Introduce transparent crystals of native gypsum (selenite), $CaSO_4 + 2H_2O = 171·65$, into a flask filled with water, and decant the clear, saturated solution when required. One part of gypsum requires, at 15° C. (59° F.), 398 parts of water for solution.

26. **Carbon Disulphide.**—Use the official carbon disulphide [*Carbonei Disulphidum*].

27. **Chlorine Water** (Chlorine Test-Solution), Cl = 35·37.—Use the official chlorine water [*Aqua Chlori*]. Since it rapidly deteriorates by keeping, it should be frequently renewed, or freshly prepared when required.

28. **Chloroform,** $CHCl_3 = 119·08$.—Use the official chloroform [*Chloroformum*].

29. **Cobaltous Nitrate Test-Solution,** $Co(NO_3)_2 + 6H_2O = 290·14$.—The crystallized, commercial salt is sufficiently pure, if, after it is dissolved in water, and the cobalt completely precipitated by ammo-

nium sulphide T.S., the filtrate leaves no residue on evaporation. To make the *test-solution*, dissolve 1 Gm. of the salt in 10 C.c. of water.

30. Cochineal Test-Solution.—See under *Indicators* (No. 50).

31. Copper (Metallic Copper), Cu = 63·18, in form of wire, foil, or turnings. The commercial article, brightened, if necessary, by scouring with diluted hydrochloric acid, is suitable for all purposes except testing for arsenic. If required for this purpose, the absence of arsenic must first be proven. A small portion (about 0·5 Gm.) of the copper is to be dissolved in hot, concentrated sulphuric acid, and this solution subjected to Gutzeit's test (see No. 14). No color should be imparted to the silver nitrate within two hours (absence of *arsenic*).

32. Cupric Ammonium Sulphate Test-Solution.—A solution of cupri-tetrammonium sulphate, $Cu(NH_3)_4SO_4 + H_2O = 245·0$. To copper sulphate T.S. add ammonia water, until the precipitate first formed is nearly, but not completely, redissolved; then filter. This solution is apt to decompose on keeping. It should be made freshly when required.

33. Cupric Sulphate Test-Solution.—Dissolve 10 Gm. of cupric sulphate, $CuSO_4 + 5H_2O = 248·8$ [*Cupri Sulphas*, U. S. P.], in enough water to make 100 C.c.

34. Cupric Tartrate Test-Solution.—See below, under Volumetric Solutions, No. 117.

35. Corallin Test-Solution.—See under *Indicators* (No. 51).

36. Diphenylamine, and Diphenylamine Test-Solution.—See under *Indicators* (No. 52).

37. Eosin Test-Solution.—See under *Indicators* (No. 53).

38. Ether.—Use the official ether [*Æther*]. It should be strictly neutral to litmus paper.

39. Ferric Ammonium Sulphate Test-Solution.—Dissolve 10 Gm. of ferric ammonium sulphate [*Ferri et Ammonii Sulphas*, U. S. P.] in enough water to make 100 C.c.

40. Ferric Chloride Test-Solution.—Dissolve 10 Gm. of ferric chloride, $Fe_2Cl_6 + 12H_2O = 539·50$ [*Ferri Chloridum*, U. S. P.], in enough water to make 100 C.c.

41. Ferrous Sulphate Test-Solution.—Dissolve a clear crystal of ferrous sulphate, $FeSO_4 + 7H_2O = 277·42$ [*Ferri Sulphas*, U. S. P.], in about 10 parts of water previously boiled to expel air. This solution should be freshly prepared immediately before use.

42. Ferrous Sulphide, FeS = 87·86.—A heavy solid, in form of black or brownish-black irregular masses, or fused into sticks, soluble in sulphuric or hydrochloric acid with copious evolution of hydrogen sulphide. On dissolving 2 Gm. of ferrous sulphide in pure nitro-hydrochloric acid diluted with a little water, evaporating the solution to dryness, and testing the residue for arsenic by Gutzeit's method (see No. 14), no color should be imparted to the silver nitrate within two hours.

43. Fluorescein Test-Solution.—See under *Indicators* (No. 54).

44. Gelatin Test-Solution.—Dissolve 1 Gm. of isinglass [*Ichthyocolla*, U. S. P.] in 50 C.c. of water, by the aid of a gentle heat, and filter if necessary. This solution should be freshly made when wanted for use.

45. Gold Chloride Test-Solution.—The commercial chloride of gold, usually prepared by dissolving gold in nitro-hydrochloric acid and carefully evaporating to dryness, mostly consists of aurochloric acid, $HAuCl_4 + 2H_2O = 375·1$, which is converted into neutral auric chloride, $AuCl_3 = 302·81$, by fusing it at a temperature not exceeding 150° C. (302° F.), moistening the residue (now consisting of auric and aurous chloride) with enough hot water to produce a syrupy liquid (whereby the aurous chloride is decomposed into auric chloride and metallic gold), and then pouring off the clear liquid from the precipitate. To prepare the *test-solution*, dissolve the liquid finally obtained in the before-mentioned process in 20 volumes of water. Or, dissolve 1 Gm. of dry auric chloride in 30 C.c. of water.

46. Hydrochloric Acid, Pure, for Tests, HCl = 36·37.—In addition to the tests prescribed for this acid in the text of the Pharmacopœia, it is required to conform to the following more rigorous tests, before it can be employed as a reagent: The addition of 1 C.c. of barium chloride T.S. to 1 C.c. of the acid diluted with 9 C.c. of water should cause no turbidity within twenty-four hours (absence of *sulphuric acid*). A crystal of diphenylamine dropped into the acid should not turn blue (absence of *free chlorine*). On substituting it for sulphuric acid in Gutzeit's test, as described under No. 14, no color should be imparted to the silver nitrate within two hours (absence of *arsenic* or *antimony*).

47. Hydrogen Sulphide, $H_2S = 33·98$.—A gas generated by treating ferrous sulphide with diluted sulphuric acid, and washing the gas by passing it through water.

48. Hydrogen Sulphide Test-Solution, or Hydrosulphuric Acid. $H_2S = 33·98$.—A saturated, aqueous solution of hydrogen sulphide. To prepare about 1 liter of the solution, treat 20 Gm. of ferrous sulphide, in a suitable apparatus, with a mixture of 20 C.c. of pure sulphuric acid, spec. grav. 1·835, and 250 C.c. of water, pass the gas through a wash-bottle containing a small quantity of water, and conduct it into a bottle of the capacity of about 1½ liters, containing 1 liter of water. When the gas is no longer absorbed, transfer the solution to small, dark amber-colored bottles, to be filled nearly to the top, pass a stream of hydrogen sulphide for a few minutes through each, and then at once stopper them tightly, and preserve them afterwards in a cool and dark place. Before putting them aside, introduce into one of these bottles a few drops of pure hydrochloric acid, and keep it in a warm place during twenty-four hours, after which time no precipitate should be found in it (absence of *arsenic*). Before any of the solution is used, it should be ascertained that it retains a strong odor of hydrogen sulphide, and that, when it is added to an equal volume of ferric chloride T.S., a copious precipitate of sulphur is formed at once.

Indicators for Acidimetry, Alkalimetry, etc.

(Nos. 49–59.)

NOTE.—Each test-solution used as *indicator* should be examined as soon as prepared, and afterwards from time to time, as to its neutrality. If necessary, it should be brought, by the cautious addition of diluted sulphuric acid, or of a dilute solution of an alkali, to such a point that, when a few drops of it are added to 25 C.c. of water, a single drop of a centinormal acid or alkali V.S., respectively, will distinctly develop the corresponding tints.

Since many of the colored test-solutions are injured by exposure to light, it is best to preserve them in dark amber-colored vials. Papers prepared with them should be kept in dark bottles or paper boxes.

49. Brazil-Wood Test-Solution.—Boil 50 Gm. of finely cut Brazil-wood [the heart-wood of *Peltophorum dubium* (Sprengel) Britton, nat. ord. *Leguminosæ*] with 100 C.c. of water during half an hour, replacing the water from time to time. Allow the mixture to cool, strain, wash the contents of the strainer with water until 100 C.c. of strained liquid are obtained, add 25 C.c. of alcohol, and filter. This solution turns purplish-red with alkalies, and yellow with acids.

50. Cochineal Test-Solution.—Macerate 1 Gm. of unbroken cochineal [*Coccus*, U.S P.], during four days, with 20 C.c. of alcohol and 60 C.c. of water. Then filter. The color of this test-solution turns violet with alkalies, and yellowish-red with acids. As an indicator it is used chiefly when ammonia or alkaline earths are present.

51. Corallin Test-Solution.—Dissolve 1 Gm. of corallin (a coloring matter derived from coal-tar, and containing rosolic and pararosolic acids) in 10 C.c. of alcohol and enough water to make 100 C.c.

52. Diphenylamine, $(C_6H_5)_2NH = 168{\cdot}65$, is in form of grayish-white or colorless crystals, of a peculiar, aromatic odor, melting at 54° C. (129·2° F.), slightly soluble in water, more soluble in acids. It is used either in the dry state, or in solution in dilute sulphuric acid, as a test for nitric acid (in sulphuric acid, water, etc.), or for chlorine (in hydrochloric acid). To test a solution for the presence of nitric acid, a small portion of it is mixed with 1 or 2 drops of diphenylamine T.S., and then concentrated sulphuric acid, *free from nitrose*, is poured in so as to form a layer beneath the solution. The presence of nitric acid is shown by a deep blue color at the zone of contact.

Diphenylamine test-solution is prepared by dissolving 0·1 Gm. of diphenylamine in 50 C.c. of diluted sulphuric acid. The solution should be colorless.

53. Eosin Test-Solution.—Dissolve 1 Gm. of commercial "yellowish" eosin [$K_2C_{20}H_6Br_4O_5$] in 30 C.c. of water. This solution is red by transmitted light, and shows a strong green fluorescence by reflected light. Acids destroy the fluorescence, and alkalies restore it.

54. Fluorescein Test-Solution,—Agitate 1 Gm. of fluorescein [$C_{20}H_{12}O_5$] with 100 C.c. of diluted alcohol, until the latter is saturated; then filter. This solution shows a strong green fluorescence, by reflected light, in presence of the least excess of an alkali.

55. Litmus Paper and Test-Solution.—Exhaust coarsely powdered litmus with boiling alcohol (which removes a peculiar, red coloring matter, erythrolitmin), and digest the residue with about an equal weight of cold water, so as to dissolve the excess of alkali present. The blue solution thus obtained, after being acidulated, may be used to make *red litmus paper*. Finally extract the residue with about 5 times its weight of boiling water, and filter. Preserve the filtrate, as *test-solution*, in wide-mouthed bottles stoppered with loose plugs of cotton to exclude dust but to admit air.

Litmus Paper, Blue.—Impregnate, with the test-solution just described, strips of white, unsized paper, free from wood-pulp, but not too porous, and dry them by suspending them on strings of clean twine.

Litmus Paper, Red.—Prepare this with the same kind of paper and in the same manner as described in the preceding paragraph. To impregnate the paper, either use the blue solution obtained from litmus, by treating the mass, after extraction by alcohol, with cold water, acidulating the same with just enough hydrochloric acid to impart to it a distinctly red tint; or, use the regular test-solution, after acidulating it in the same manner.

Neither blue nor red litmus paper should have a very intense color.

Preserve the test-paper in paper boxes or bottles, so as to exclude dust and acid or ammoniacal vapors.

56. Methyl-Orange Test-Solution.—Dissolve 1 Gm. of methyl-orange [the sodium or ammonium salt of dimethylamidoazobenzolsulphonic acid, $HC_{14}H_{14}N_3SO_3 = 304{\cdot}47$; also known as helianthin, or tropæolin D, or Poirrier's Orange 3 P] in 1000 C.c. of water. Add to it, carefully, diluted sulphuric acid, in drops, until the liquid turns red and just ceases to be transparent. Then filter.

The solution acquires a yellow color when brought in contact with alkali hydrates, carbonates, or bicarbonates. Carbonic acid does not affect it, but sulphuric, hydrochloric, and other acids change its color to crimson. It is not suited for use with organic acids.

57. Phenolphtalein Test-Solution.—Dissolve 1 Gm. of phenolphtalein [$C_{20}H_{14}O_4$] in 100 C.c. of diluted alcohol. The solution is colored deep purplish-red by alkali hydrates or carbonates; bicarbonates and most other salts do not produce such color; acids render the reddened solution colorless. It is not suitable as an indicator for ammonia or bicarbonates.

Phenolphtalein Paper is prepared by impregnating white, unsized paper with the test-solution and drying it.

58. Rosolic Acid Test-Solution.—Dissolve 1 Gm. of commercial rosolic acid [chiefly methylaurin, $C_{20}H_{16}O_3 = 303{\cdot}28$] in 10 C.c. of diluted alcohol, and add enough water to make 100 C.c. The solution turns violet-red with alkalies, yellow with acids. In place of rosolic acid, commercial pæonin (also known as aurin R) [chiefly $C_{19}H_{14}O_3 = 289{\cdot}31$] may be employed.

59. Turmeric Tincture.—Digest any convenient quantity of ground curcuma root [from *Curcuma longa* Linné, nat. ord. *Scitaminceæ*] repeatedly with small quantities of water, and throw this liquid away. Then digest the dried residue for several days with 6 times its weight of alcohol, and filter.

Turmeric Paper.—Impregnate white, unsized paper with the tincture, and dry it. The tincture, as well as the paper, turns brown with alkalies, and the yellow color is restored by acids. Boric acid, however, even in presence of hydrochloric acid, turns the color to reddish-brown, and this is changed to bluish-black by ammonia.

---

60. Indigo Test-Solution.—Place 6 Gm. (3·3 C.c.) of fuming sulphuric acid into a beaker well cooled by immersion in water, and stir into it, very gradually, 1 Gm. of finely powdered Bengal indigo. Set the mixture aside for two days, then pour it into 20 C.c. of water, and decant. Or, dissolve 1 Gm. of commercial indigo-carmine (the sodium or potassium salt of sulphindigotic acid) in 150 C.c. of water.

61. Iodine Test-Solution.—For preparing the ordinary test-solution (as a reagent for starch, alcohol by iodoform test, etc.), iodine, I = 126·53, fulfilling the requirements of the Pharmacopœia [see *Iodum*, U. S. P.], is sufficiently pure. For this purpose dissolve 1 Gm. of iodine and 3 Gm. of potassium iodide in 50 C.c. of water.

For use in volumetric analysis, or in other cases where the ordinary impurities present in official iodine are objectionable, *Purified Iodine* must be employed. See under No. 120.

62. Iron, Metallic, Fe = 55·88.—Bright and perfectly clean iron in the form of wire, sheet, or filings, according to the uses to be made of it. For making solutions of pure iron salts, fine, thin, bright wire (so-called florists' wire) should be used. For detecting copper, bright pieces of sheet iron or knitting-needles are used; for detecting nitric acid, by reduction to ammonia, iron filings are preferable.

63. Lead Acetate Test-Solution.—Dissolve 10 Gm. of clear, transparent crystals of lead acetate, $Pb(C_2H_3O_2)_2 + 3H_2O = 378·0$ [*Plumbi Acetas*, U. S. P.], free from adhering lead carbonate, in enough water to make 100 C.c. Preserve the solution in well-stoppered bottles.

64. Basic Lead Acetate Test-Solution.—Use the official solution of lead subacetate [*Liquor Plumbi Subacetatis*].

65. Litmus Paper and Test-Solution.—See under *Indicators* (No. 55).

66. Magnesia Mixture.—Dissolve 10 Gm. of magnesium sulphate [*Magnesii Sulphas*, U. S. P.], and 20 Gm. of ammonium chloride [*Ammonii Chloridum*, U. S. P.], in 80 C.c. of water, add 42 C.c. of ammonia water, set the mixture aside for a few days in a well-stoppered vessel, and filter. It should never be used freshly made.

67. Magnesium Sulphate Test-Solution.—Dissolve 10 Gm. of magnesium sulphate, $MgSO_4 + 7H_2O = 245·84$ [*Magnesii Sulphas*, U. S. P.], in enough water to make 100 C.c.

68. Mercuric Chloride Test-Solution.—Dissolve 5 Gm. of mercuric chloride, $HgCl_2 = 270·54$ [*Hydrargyri Chloridum Corrosivum*, U. S. P.], in enough water to make 100 C.c.

69. Mercuric Potassium Iodide Test-Solution.—Use the decinormal mercuric potassium iodide volumetric solution (No. 121).

70. Alkaline Mercuric Potassium Iodide Test-Solution. (*Nessler's Solution.*)—Dissolve 5 Gm. of potassium iodide [*Potassii Iodidum*, U. S. P.] in 5 C.c. of hot water, and add to this a hot solution of 2·5 Gm. of mercuric chloride [*Hydrargyri Chloridum Corrosivum*, U. S. P.] in 10 C.c. of water. To the turbid, red mixture add 16 Gm. of potassium hydrate [*Potassa*, U. S. P.], dissolved in 40 C.c. of water, and finally make up the volume to 100 C.c. A surplus of red mercuric iodide deposits on cooling, and may be left in the bottle, the clear solution being decanted as needed.

71. Mercurous Nitrate Test-Solution, $Hg_2(NO_3)_2 + 2H_2O = 559·3$.—Into a porcelain capsule put 1 Gm. of pure mercury with 0·5 C.c. of pure nitric acid and 0·5 C.c. of distilled water, and place it for 24 hours into a cool, dark room. Separate and drain the crystals, and dissolve them in 10 C.c. of water. Preserve the solution in a dark amber-colored bottle, into which a small globule of mercury has been placed.

72. Methyl Alcohol, $CH_3OH = 31·93$.—For the identification of salicylic acid, the rectified, commercial wood-alcohol, having a specific gravity of about 0·820, is sufficiently pure, if it forms a clear, transparent mixture with an equal volume of distilled water.

73. Methyl-Orange Test-Solution.—See under *Indicators* (No. 56).

74. Nitric Acid, Pure, for Tests, $HNO_3 = 62·89$.—In addition to the tests prescribed for this acid in the text of the Pharmacopœia, it is required to conform to the following more rigorous test before it can be used as a reagent: On supersaturating 0·5 C.c. of the acid with pure potassium hydrate T.S., and testing a portion of this solution by Fleitmann's method (see under No. 13), no color should be imparted to the silver nitrate within two hours (absence of *arsenic*).

75. Fuming Nitric Acid (Red Fuming Nitric Acid).—The commercial acid will answer, if it is of specific gravity 1·450 or over. It should be carefully kept in glass-stoppered bottles in a cool place.

76. Oxalic Acid Test-Solution.—Use the decinormal volumetric solution (No. 123).

77. Phenolphtalein Test-Solution.—See under *Indicators* (No. 57).

78. Picric Acid Test-Solution.—Dissolve 1 Gm. of pure, distinctly crystalline picric acid (trinitrophenol), $C_6H_2(NO_2)_3OH = 228·57$, in 100 C.c. of water, cool the solution, and filter, if necessary.

79. Platinic Chloride Test-Solution.—Heat 1 Gm. of pure platinum, in chips, with 6 C.c. of concentrated hydrochloric acid to 80° C. (186° F.), and very gradually add 1 C.c. of strong nitric acid (spec.

grav. 1·414) until very nearly all the platinum is dissolved. Evaporate the solution to dryness on a water-bath, moisten the residue with a few drops of hydrochloric acid, and again evaporate to expel the excess of acid. Dissolve the residue in 20 C.c. of water. The *test-solution* may also be prepared by dissolving 1·7 Gm. of neutral platinic chloride, $PtCl_4 = 335·78$, or 2·6 Gm. of chloroplatinic acid, $H_2PtCl_6 + 6H_2O = 516·28$, in 20 C.c. of water. On evaporating a small portion of the solution to dryness and igniting the residue, pure, metallic platinum should be left behind, which should yield nothing soluble to nitric acid.

80. Potassium Carbonate Test-Solution.—Dissolve 10 Gm. of anhydrous potassium carbonate, $K_2CO_3 = 137·91$ [prepared from *Potassii Carbonas*, U. S. P.], in enough water to make 100 C.c.

81. Potassium Chromate Test-Solution.—Dissolve 1 Gm. of potassium chromate, $K_2CrO_4 = 193·9$, in enough water to make 10 C.c. On adding silver nitrate T.S. to a little of the solution, a red precipitate is produced which should be completely dissolved by nitric acid (absence of *chloride*). Another portion of the solution, mixed with an equal volume of diluted hydrochloric acid, should yield no precipitate with barium chloride T.S. (absence of *sulphate*).

82. Potassium Cyanide Test-Solution.—This should be freshly prepared, when required, by dissolving 1 Gm. of potassium cyanide, $KCN = 65·01$ [*Potassii Cyanidum*, U. S. P.], in 4 parts of water.

83. Potassium Dichromate.—Use the official potassium bichromate, $K_2Cr_2O_7 = 293·78$ [*Potassii Bichromas*].

84. Potassium Dichromate Test-Solution.—Dissolve 10 Gm. of potassium dichromate [*Potassii Bichromas*, U. S. P.] in enough water to make 100 C.c.

85. Potassium Ferricyanide Test-Solution.—Dissolve 1 part of potassium ferricyanide, $K_6Fe_2(CN)_{12} = 657·7$, in about 10 parts of water. This solution should be made freshly when required, as it is rapidly decomposed by light. A freshly prepared, aqueous solution, when mixed with some ferric chloride T.S. and diluted with water, should show a brown tint, free from turbidity or a shade of green.

86. Potassium Ferrocyanide Test-Solution.—Dissolve 10 Gm. of potassium ferrocyanide, $K_4Fe(CN)_6 + 3H_2O = 421·76$, in enough water to make 100 C.c.

87. Potassium Hydrate Test-Solution, $KOH = 55·99$.—Use the official solution of potassa [*Liquor Potassæ*]. For use in Fleitmann's test for arsenic (see above, No. 13), it should have previously been subjected, by itself, to this test, for at least two hours, with negative result (absence of *arsenic*).

88. Potassium Iodide Test-Solution.—Dissolve 16·566 Gm. of potassium iodide, $KI = 165·56$ [*Potassii Iodidum*, U. S. P.], in enough water to make 100 C.c., and keep the solution in dark amber-colored, well-stoppered bottles to prevent the formation of iodate. The solution should be frequently renewed, or freshly prepared when required. (This solution is of normal strength $= \frac{N}{1}$ V.S., so as to permit of its use for volumetric and gasometric purposes also.)

89. Potassium Nitrate.—The dry salt, $KNO_3 = 100·92$ [*Potassii Nitras*, U. S. P.], responding to the tests of purity required by the Pharmacopœia, particularly to those for absence of chloride and sulphate.

90. Potassium Permanganate, $KMnO_4 = 157·67$.—See below, under No. 127.

91. Potassium Sulphate Test-Solution.—Dissolve 1 Gm. of potassium sulphate, $K_2SO_4 = 173·88$ [*Potassii Sulphas*, U. S. P.], in enough water to make 115 C.c. (This solution is of decinormal strength $= \frac{N}{10}$ V.S., so as to permit of its use for volumetric purposes also, as a substitute for decinormal sulphuric acid, when it is desired not to disturb the neutrality of a liquid.)

92. Potassium Sulphocyanate Test-Solution, $KSCN = 96·99$.—Use the decinormal volumetric solution (No. 129).

93. Pyrogallol.—Use the official pyrogallol, $C_6H_3(OH)_3 = 125·7$ [*Pyrogallol*].

94. Rosolic Acid.—See under *Indicators* (No. 58).

95. Silver Ammonium Nitrate Test-Solution.—Dissolve 1 Gm. of silver nitrate [*Argenti Nitras*, U. S. P.] in 20 C.c. of water, and add ammonia water, drop by drop, until the precipitate first produced is almost, but not entirely, redissolved. Filter the solution, and preserve it in dark amber-colored and well-stoppered bottles.

96. Silver Nitrate Test-Solution, $AgNO_3 = 169·55$.—For ordinary purposes, use the decinormal volumetric solution (see No. 130). For Gutzeit's test (No. 14), use a saturated solution of silver nitrate in water acidulated with about 1 one per cent. of nitric acid.

97. Silver Sulphate Test-Solution.—Dissolve 1 Gm. of silver nitrate [*Argenti Nitras*, U. S. P.] in 0·5 C.c. of warm water, and add 1·5 C.c. of pure, concentrated sulphuric acid. On cooling, small transparent crystals of silver sulphate, $Ag_2SO_4 = 311·14$, separate. Carefully pour off the acid liquid, wash the crystals repeatedly, by decantation, with cold water, transfer them to a bottle, add 100 C.c. of water, and agitate so as to produce a saturated solution. For use, decant a sufficient quantity of the latter.

98. Sodium Acetate Test-Solution.—Dissolve 10 Gm. of sodium acetate (*Sodii Acetas*, U. S. P.] in enough water to make 100 C.c.

99. Sodium Bitartrate Test-Solution.—Dissolve 150 Gm. of tartaric acid [*Acidum Tartaricum*, U. S. P.] in 100 C.c. of hot water, and divide the solution into two equal portions. Neutralize one of these accurately with sodium bicarbonate (which will require about 84 Gm. of this salt), and then add the other portion of the acid solution. On cooling, crystals of sodium bitartrate, $NaHC_4H_4O_6 + H_2O = 189·6$, will separate. Remove these, dry them, and keep them in well-stoppered bottles. The *test-solution* is freshly prepared, when required, by dissolving 1 Gm. of the salt in 4 C.c. of water.

100. **Sodium Carbonate.**—The anhydrous salt, $Na_2CO_3 = 105{\cdot}85$, conforming to the tests of purity prescribed by the Pharmacopœia for *Sodii Carbonas*, but absolutely free from chloride or sulphate.

101. **Sodium Carbonate Test-Solution.**—Dissolve 10·6 Gm. of anhydrous sodium carbonate [No. 100; $Na_2CO_3 = 105{\cdot}85$] in enough water to make 100 C.c. (This solution is of double normal strength $= \frac{2}{N}$ V.S., so as to permit of its use for volumetric purposes also.)

102. **Sodium Cobaltic Nitrite Test-Solution.**—$Co_2(NO_2)_6 6NaNO_2 + H_2O = 824{\cdot}32$. Dissolve 4 Gm. of cobaltous nitrate, $Co(NO_3)_2 + 6H_2O = 290{\cdot}14$, and 10 Gm. of sodium nitrite, $NaNO_2 = 68{\cdot}93$, in about 50 C.c. of water, add 2 C.c. of acetic acid, and dilute with enough water to make 100 C.c. Should any of the nitrous acid be lost by keeping the solution, a few drops of acetic acid may be added.

103. **Sodium Hydrate Test-Solution,** $NaOH = 39{\cdot}96$.—Use the official solution of sodium hydrate [*Liquor Sodæ*, U. S. P.].

104. **Sodium Hyposulphite,** or Thiosulphate, $Na_2S_2O_3 + 5H_2O = 247{\cdot}64$.—See below, under No. 133.

105. **Sodium Nitrite,** $NaNO_2 = 68{\cdot}93$.—The purest commercial salt, generally in form of pencils, is sufficiently pure.

106. **Sodium Nitroprusside Test-Solution.**—Dissolve 1 part of sodium nitroprusside, $Na_2Fe(NO)(CN)_5 + 2H_2O = 297{\cdot}67$, in 10 parts of water immediately before using.

107. **Sodium Phosphate Test-Solution.**—Dissolve 10 Gm. of sodium phosphate, $Na_2HPO_4 + 12H_2O = 357{\cdot}32$ [*Sodii Phosphas*, U. S. P.], in enough water to make 100 C.c.

108. **Stannous Chloride Test-Solution.**—Heat pure tin (see No. 113), in form of foil or granules, with concentrated hydrochloric acid, taking care that the metal be in excess. When the acid is saturated, crystals of stannous chloride, $SnCl_2 + 2H_2O = 225{\cdot}46$, begin to form. Remove and drain these, dissolve them in 10 parts of water, and preserve the solution in well-stoppered bottles, into each of which a granule of pure tin, or a piece of pure tin-foil, has previously been introduced.

For Bettendorff's test (see above, No. 12), pure concentrated hydrochloric acid is saturated with the freshly prepared crystals.

109. **Starch Test-Solution.**—Mix 1 Gm. of starch with 10 C.c. of cold water, and then add enough boiling water, under constant stirring, to make about 200 C.c. of a thin, transparent jelly. If it is desired to preserve this test-solution for any length of time, 10 Gm. of zinc chloride, $ZnCl_2 = 135{\cdot}84$ [*Zinci Chloridum*, U. S. P.], should be added to it, and the solution transferred to small bottles, which should be well stoppered.

110. **Sulphuric Acid, Pure, for Tests,** $H_2SO_4 = 97{\cdot}82$.—The sulphuric acid of the Pharmacopœia, which may have a specific gravity as low as 1·835, will answer as a reagent for most purposes, provided it is of the required degree of purity. But when "concentrated" sulphuric acid is specially directed in a test, it is intended that the strongest obtainable, pure acid, of a specific gravity of not less than 1·840, be employed.

In addition to the tests prescribed for this acid in the text of the Pharmacopœia, it is required to conform to the following more rigorous tests before it can be employed as a reagent. If 1 C.c. of diphenylamine T.S. (see No. 52) be carefully poured, as a separate layer, upon 5 C.c. of sulphuric acid, contained in a test-tube, no distinct blue color should appear in the zone of contact (absence of *nitric acid*). If a few crystals of pyrogallol [*Pyrogallol*, U. S. P.] be dissolved in about 1 C.c. of pure water, and this solution be carefully poured, as a separate layer, upon some of the sulphuric acid, contained in a test-tube, no brown color should appear in the zone of contact (absence of *nitric* or *nitrous acid*). If a small portion of the acid be subjected to Gutzeit's test, as described under No. 14, no color should be imparted to the silver nitrate within two hours (absence of *arsenic*, etc.).

If it is impossible to obtain any sulphuric acid which will comply with each of these requirements, two kinds of the acid may be kept, one absolutely free from arsenic, for making the arsenic tests; the other free from nitrose (nitric and nitrous acids), for the detection of nitric acid.

111. **Tannic Acid Test-Solution.**—Dissolve 1 Gm. of tannic acid, $HC_{14}H_9O_9 = 321{\cdot}22$ [*Acidum Tannicum*, U. S. P.], in 1 C.c. of alcohol and enough water to make 10 C.c., immediately before use.

112. **Tartaric Acid Test-Solution.**—Dissolve 1 part of tartaric acid, $H_2C_4H_4O_6 = 149{\cdot}64$ [*Acidum Tartaricum*, U. S. P.], in 3 parts of water. In the volumetric estimation of soda in potassa, directed by the preceding text of the Pharmacopœia, the tartaric acid test-solution employed for precipitating the potassa should contain 3 Gm. of the acid in 20 C.c. Since fungous growths rapidly destroy the solution of tartaric acid, it should be prepared only as wanted.

113. **Tin.**—Pure metallic tin, $Sn = 118{\cdot}8$, in form of granules. Its solution in hydrochloric acid should not be precipitated by potassium sulphate T.S. (absence of *lead*), and, when examined by Gutzeit's test, as described under No. 14, it should not cause silver nitrate to become colored within two hours (absence of *arsenic*).

114. **Turmeric Paper and Tincture.**—See under *Indicators* (No. 59).

115. **Zinc.**—Metallic zinc, $Zn = 65{\cdot}1$, preferably in the form of thin pencils about 5 Mm. in diameter, prepared by fusing the metal and casting it in moulds, or in form of thin sheets. It should respond to all the tests required by the text of the Pharmacopœia, and in addition, when examined by Gutzeit's test, as described under No. 14, it should not cause the silver nitrate to become colored within two hours (absence of *arsenic*).

116. Zinc-Iodide-Starch Test-Solution.—To 100 C.c. of freshly prepared starch test-solution (see No. 109) add 5 Gm. of zinc chloride [*Zinci Chloridum*, U. S. P.] and 3 Gm. of zinc iodide [*Zinci Iodidum*, U. S. P.]. Preserve the colorless solution carefully in small, dark amber-colored and well-stoppered vials.

III. VOLUMETRIC SOLUTIONS.

NOTE.—Since most of the volumetric instruments (burettes, pipettes, mixing cylinders, flasks, etc.) which are for sale in the market are graduated to hold the number of cubic centimeters indicated by weighing into them the corresponding number of grammes of water at the temperature of 15·556° C. (60° F.), or 15° C. (59° F.), it is necessary not to deviate materially from this temperature in making the volumetric solutions, or in using them in testing.

All measuring vessels employed for volumetric determinations should agree among themselves in accuracy of graduation.

All bottles in which volumetric solutions are to be kept, as well as the burettes or pipettes in which they are to be measured, should, prior to use, be rinsed with a small quantity of the solution they are to contain.

Volumetric solutions are designated as normal $\left(\frac{N}{1}\right)$ when they contain in 1 liter the molecular weight of the active reagent, expressed in grammes, and reduced to the valency corresponding to one atom of replaceable hydrogen or its equivalent.

Thus, hydrochloric acid, $HCl = 36{\cdot}37$, having but one H atom replaceable by a basic element, has 36·37 Gm. of HCl in 1000 C.c. of the normal volumetric solution; while sulphuric acid, $H_2SO_4 = 97{\cdot}82$, having two replaceable H atoms, contains only one-half this number, or 48·91 grammes of H_2SO_4 in 1000 C.c. of its normal solution. Potassium hydrate, $KOH = 55{\cdot}99$, has but one K to replace one H in acids, hence its normal solution contains 55·99 grammes of KOH in one liter. Two molecules of potassium permanganate, $2KMnO_4 = 315{\cdot}34$, in oxidation, give off five atoms of O, which are equivalent to ten atoms of H; hence its normal solution should contain $\frac{315{\cdot}34}{10}$ or 31·534 Gm. in 1 liter.

Solutions containing in 1 liter one-tenth of the quantity of the active reagent in the normal solution are called decinormal $\left(\frac{N}{10}\right)$; those containing one one-hundredth, centinormal $\left(\frac{N}{100}\right)$; those containing twice the amount, double-normal $\left(\frac{2}{N}\right)$; half the amount, seminormal $\left(\frac{N}{2}\right)$.

Solutions containing quantities of the active reagent having *no* simple relation to the molecular weight are called empirical.

In the following list full decimals are given, which, however (especially when delicate balances and weights are not at hand), are in practice frequently abbreviated or rounded off, as, for instance, oxalic acid: 62·85 Gm. to 63 Gm.

When weighing out portions of a substance which is to be tested volumetrically, it will, in most cases, be advantageous to weigh out such a multiple of the amount required, as will suffice for several repetitions of the test, and will, at the same time, bring the amount to be weighed out as near to a whole number of grammes as possible.

117. Alkaline Cupric Tartrate Volumetric Solution.

[FEHLING'S SOLUTION.]

A. The Copper Solution.—Dissolve 34·64 Gm. of carefully selected, small crystals of pure cupric sulphate, showing no trace of efflorescence or of adhering moisture, in a sufficient quantity of water to make the solution measure, at or near 15° C. (59° F.), exactly 500 C.c.

Keep this solution in small, well-stoppered bottles.

B. The Rochelle Salt Solution.—Dissolve 173 Gm. of potassium and sodium tartrate [*Potassii et Sodii Tartras*, U. S. P.], and 125 Gm. of potassium hydrate [*Potassa*, U. S. P.], in a sufficient quantity of water to make the solution measure, at or near 15° C. (59° F.), exactly 500 C.c.

Keep the solution in small, rubber-stoppered bottles.

For use, mix exactly equal volumes of the two solutions at the time required.

One Cubic Centimeter of the mixed solution is the equivalent of:

	Gramme.
Cupric Sulphate, crystallized, $CuSO_4 + 5H_2O$	0·03464
Cupric Tartrate, $CuC_4H_4O_6 + 3H_2O$	0·03685
Glucose, anhydrous, $C_6H_{12}O_6$	0·00500

118. Decinormal Bromine Volumetric Solution.

[KOPPESCHAAR'S SOLUTION.]

$Br = 79{\cdot}76$. 7·976 Gm. in 1 Liter.

($NaBrO_3 = 150{\cdot}64$.—$NaBr = 102{\cdot}76$.)

($KBrO_3 = 166{\cdot}67$.—$KBr = 118{\cdot}79$.)

Dissolve 3 Gm. of sodium bromate and 50 Gm. of sodium bromide (or 3·2 Gm. of potassium bromate and 50 Gm. of potassium bromide) in enough water to make, at or near 15° C. (59° F.), 900 C.c. Of this solution transfer 20 C.c., by means of a pipette, into a bottle having a capacity of about 250 C.c., pro-

vided with a glass stopper; add 75 C.c. of water, next 5 C.c. of pure hydrochloric acid, and immediately insert the stopper. Shake the bottle a few times, then remove the stopper just sufficiently to quickly introduce 5 C.c. of potassium iodide T.S., taking care that no bromine vapor escape, and immediately stopper the bottle. Agitate the bottle thoroughly, remove the stopper and rinse it and the neck of the bottle with a little water so that the washings flow into the bottle, and then add from a burette decinormal sodium hyposulphite V.S., until the iodine tint is exactly discharged, using towards the end a few drops of starch T.S. as indicator. Note the number of C.c. of the sodium hyposulphite V.S. thus consumed, and then dilute the bromine solution so that equal volumes of it and of decinormal sodium hyposulphite V.S. will exactly correspond to each other under the conditions mentioned above.

EXAMPLE.—Assuming that the 20 C.c. of the bromine solution have required 25·2 C.c. of the hyposulphite to completely discharge the iodine tint, the bromine solution must be diluted in the proportion of 20 to 25·2. Thus, if 850 C.c. of it are remaining, they must be diluted with water to measure 1071 C.c.

After the solution is thus diluted, a new trial should be made in the manner above described, in which 25 C.c. of the decinormal sodium hyposulphite V.S. should exactly discharge the tint of the iodine liberated by the bromine set free from the 25 C.c. of bromine solution.

Keep the solution in dark amber-colored glass-stoppered bottles.

One Cubic Centimeter of Decinormal Bromine Solution V.S. is the equivalent of:

	Gramme.
Bromine, Br	0·007976
Carbolic Acid, C_6H_5OH	0·001563

The following article is tested with this solution:

	Gm. taken.	C.c. required.	Percent. of strength indicated.
Acidum Carbolicum	0·039	24	96 of pure phenol.

119. Normal Hydrochloric Acid.

HCl = 36·37. 36·37 Gm. in 1 Liter.

Mix 130 C.c. of hydrochloric acid of specific gravity 1·163 with enough water to make it measure, at or near 15° C. (59° F.), 1000 C.c.

Of this liquid (which is still too concentrated) carefully measure 10 C.c. into a flask, add a few drops of phenolphtalein T.S., and gradually add, from a burette, potassium hydrate V.S., until the red tint produced by it no longer disappears on vigorous shaking, but is not deeper than pale pink. Note the number of C.c. of potassium hydrate V.S. consumed, and then dilute the acid solution so that equal volumes of this and of the potassium hydrate V.S. neutralize each other.

EXAMPLE.—Assuming that 10 C.c. of the acid solution first prepared required exactly 11 C.c. of potassium hydrate V.S., each 10 C.c. of the former must be diluted to 11 C.c., or the whole of the remaining acid solution in the same proportion. Thus, if 950 C.c. are remaining, 95 C.c. of water must be added.

After the liquid is thus diluted, a new trial should be made in the manner above described, in which 50 C.c. of the acid solution should require for neutralization exactly 50 C.c. of potassium hydrate V.S. If necessary, a new adjustment should then be made to render the correspondence perfect.

One Cubic Centimeter of Normal Hydrochloric Acid is the equivalent of:

	Gramme.
Hydrochloric Acid, absolute, HCl	0·03637

NOTE.—Normal hydrochloric acid is in every respect equivalent in neutralizing power to normal sulphuric acid (see below, No. 134), and may be employed, if more convenient, for the same purposes.

120. Decinormal Iodine Volumetric Solution.

I = 126·53. 12·653 Gm.* in 1 Liter.

Dissolve 12·653 Gm.* of pure iodine (see below) in a solution of 18 Gm. of pure potassium iodide in 300 C.c. of water. Then add enough water to make the solution measure, at or near 15° C. (59° F.), exactly 1000 C.c.

Transfer the solution to small, glass-stoppered vials, which should be kept in a dark place.

Preparation of Pure Iodine.—Heat powdered iodine in a porcelain dish placed over a boiling water-bath, and stir it constantly with a glass rod, so that the adhering moisture, together with any cyanogen iodide and most of the iodine bromide and chloride that may be present, may be vaporized. After twenty minutes transfer the iodine to a porcelain or other non-metallic mortar, and triturate it with about 5 per cent. of its weight of pure, dry potassium iodide, so as to decompose any remaining iodine bromide and chloride. Then return the mass to the dish, cover it with a clean glass funnel, and heat the dish on a sand-bath. Detach the sublimed, pure iodine, and keep it in well-stoppered bottles, in a cool place.

* Instead of taking 12·653 Gm., this figure is often rounded off to 12·65, or even to 12·7. But, whenever a delicate balance is available, the exact amount above directed should be taken.

One Cubic Centimeter of Decinormal Iodine V.S. is the equivalent of:

	Gramme.
Iodine, I	0·012653
Arsenic Trioxide (arsenous acid), As_2O_3	0·004942
Potassium Sulphite, crystallized, $K_2SO_3 + 2H_2O$	0·009692
Sodium Bisulphite, $NaHSO_3$	0·005193
Sodium Hyposulphite (Thiosulphate), crystals, $Na_2S_2O_3 + 5H_2O$	0·024764
Sodium Sulphite, crystallized, $Na_2SO_3 + 7H_2O$	0·012579
Sulphur Dioxide, SO_2	0·003195
Antimony and Potassium Tartrate, crystallized, $2K(SbO)C_4H_4O_6 + H_2O$	0·016560

The following articles are tested with this solution:

	Gm. taken.	C.c. required.	Percent. of strength indicated.
Acidum Arsenosum	0·1	20·0	98·8 of As_2O_3.
Acidum Sulphurosum	2·0	40·0	6·4 of SO_2.
Antimonii et Potassii Tartras (crystallized)	0·331	20·0	100 of pure salt.
Liquor Acidi Arsenosi	24·7 C.c.	49·4 to 50	1 of As_2O_3.
Liquor Potassii Arsenitis	24·7 C.c.	49·4 to 50	1 of As_2O_3.
Sodii Bisulphis	0·26	45·0	90 of pure salt.
Sodii Hyposulphis	0·25	9·9	98·1 of cryst. salt.
Sodii Sulphis	0·63	48·0	96 of cryst. salt.

121. Decinormal Mercuric Potassium Iodide Volumetric Solution.

[Mayer's Solution.]

$HgI_2 + 2KI = 783·98$. 39·2 Gm. in 1 Liter.

Dissolve 13·546 Gm. of pure mercuric chloride in 600 C.c. of water, and 49·8 Gm. of pure potassium iodide in 100 C.c. of water. Mix the two solutions, and then add enough water to make the mixture measure, at or near 15° C. (59° F.), exactly 1000 C.c.

One Cubic Centimeter of Decinormal Mercuric Potassium Iodide V.S. is the equivalent of:

	Gramme.
Mercuric Potassium Iodide, $HgI_2 + 2KI$	0·0392

122. Normal Oxalic Acid Volumetric Solution.

$H_2C_2O_4 + 2H_2O = 125·7$. 62·85 Gm.* in 1 Liter.

Dissolve 62·85 Gm.* of pure oxalic acid (see below) in enough water to make, at or near 15° C. (59° F.), exactly 1000 C.c.

Pure Oxalic Acid, crystallized, is in form of colorless, transparent, clinorhombic crystals which, on ignition upon platinum-foil, leave no residue. One part of it is completely soluble in 14 parts of water at 15° C. (59° F.). Oxalic acid which leaves a residue on ignition, or on solution in water, must be purified, which may be done as follows: To 1 part of the acid add 10 parts of cold water, and shake until the latter is saturated. Filter off the solution from the undissolved crystals, evaporate the filtrate to about three-fourths of its volume, and set it aside so that the fixed salts which it contains may crystallize out. Carefully decant the liquid from the crystals, concentrate it by evaporation, and set it aside to crystallize, stirring occasionally to prevent the formation of large crystals which might enclose moisture. Drain the crystals in a funnel, dry them carefully on blotting paper, and preserve them in well-stoppered bottles.

Note.—Normal oxalic acid volumetric solution is in every respect equivalent in neutralizing power to *normal sulphuric acid* (No. 134), or *normal hydrochloric acid* (No. 119), and may be employed, if more convenient, for the same purposes. The solution, however, has a tendency to crystallize at the point of the burette.

One Cubic Centimeter of Normal Oxalic Acid V.S. is the equivalent of:

	Gramme.
Oxalic Acid, crystallized, $H_2C_2O_4 + 2H_2O$	0·06285
Ammonia Gas, NH_3	0·01701
Sodium Hydrate, NaOH	0·03996
Potassium Hydrate, KOH	0·05599
Potassium Permanganate, $KMnO_4$	0·03153

123. Decinormal Oxalic Acid Volumetric Solution.

$H_2C_2O_4 + 2H_2O = 125·7$. 6·285 Gm.† in 1 Liter.

Dissolve 6·285 Gm.† of pure oxalic acid (see under No. 122) in enough water to make, at or near 15° C. (59° F.), exactly 1000 C.c.

* This is frequently rounded off to 63 Gm., when a delicate balance and exact weights are not at hand.
† Generally rounded off to 6·3 Gm., when a delicate balance and exact weights are not available.

One Cubic Centimeter of Decinormal Oxalic Acid V.S. is the equivalent of:

	Gramme.
Oxalic Acid, crystallized, $H_2C_2O_4 + 2H_2O$	0·006285
Ammonia Gas, NH_3	0·001701
Calcium Hydrate, $Ca(OH)_2$	0·003691
Potassium Hydrate, KOH	0·005599
Potassium Permanganate, $KMnO_4$	0·0031534
Sodium Hydrate, NaOH	0·003996

The following articles are tested with this solution:

	Gm. taken.	C.c. required.	Percent. of strength indicated.
Liquor Calcis	50·0	★20·0	★0·14 of $Ca(OH)_2$.
Potassii Iodidum (alkalinity, K_2CO_3)	1·0	0·05	0·034 of alkali.
Potassii Permanganas	0·1	31·3	98·70 of pure salt.

124. Decinormal Potassium Dichromate Volumetric Solution.

$K_2Cr_2O_7 = 293·78$. 4·896 Gm.* in 1 Liter.

Dissolve 4·896 Gm.* of pure potassium dichromate (see below) in enough water to make, at or near 15° C. (59° F.), exactly 1000 C.c.

Pure Potassium Dichromate for use in volumetric analysis, besides responding to the tests given in the text of the Pharmacopœia (under *Potassii Bichromas*), must conform to the following tests. In a solution of 0·5 Gm. of the salt in 10 C.c. of water rendered acid by 0·5 C.c. of nitric acid, no visible change should be produced either by barium chloride T.S. (absence of *sulphate*), or by silver nitrate T.S. (absence of *chloride*). In a mixture of 10 C.c. of the aqueous solution (1 in 20) with 1 C.c. of ammonia water, no precipitate should be produced by ammonium oxalate T.S. (absence of *calcium*).

When used with phenolphtalein as indicator, to neutralize alkalies, the volumetric solution of potassium dichromate is decinormal when it contains 14·689 Gm. in 1 liter. It is then the exact equivalent of any decinormal acid, corresponding to the amounts of alkalies quoted, for instance, under Decinormal Oxalic Acid V.S. (No. 123).

When used as an oxidizing agent to convert ferrous into ferric salts, or to liberate iodine from potassium iodide, the solution just mentioned (containing 14·689 Gm. in 1 liter) has the effect of a $\frac{3N}{10}$ volumetric solution, and a solution of one-third of this strength, containing 4·896 Gm. in 1 liter, has the value of a decinormal solution, and is the equivalent of equal volumes of decinormal potassium permanganate V.S., or, in the case of iodine liberated from potassium iodide, it is the equivalent of equal volumes of decinormal sodium hyposulphite V.S. For titrating iron in *ferrous* compounds, it is used in the following manner. Introduce the aqueous solution of the ferrous salt into a flask and, if it is not already acid, render it so with sulphuric acid. Now add, gradually, decinormal potassium dichromate V.S. from a burette, until a drop taken out upon a white surface no longer shows a blue color with a drop of freshly prepared potassium ferricyanide T.S.

Decinormal potassium dichromate V.S. may also be used, in conjunction with potassium iodide (from which it liberates iodine) and sulphuric acid, for adjusting the titer of sodium hyposulphite (thiosulphate) V.S. and, by its means, that of the iodine V.S.

One Cubic Centimeter of Decinormal Potassium Dichromate V.S. is the equivalent of:

	Gramme.
Potassium Dichromate, $K_2Cr_2O_7$	0·0048963
Iron, in ferrous compounds	0·005588
Ferrous Carbonate, $FeCO_3$	0·011573
Ferrous Sulphate, anhydrous, $FeSO_4$	0·015170
Ferrous Sulphate, crystallized, $FeSO_4 + 7H_2O$	0·027742
Ferrous Sulphate, dried, $2FeSO_4 + 3H_2O$	0·017864
Potassium Hydrate, KOH	0·001866
Sodium Hyposulphite (Thiosulphate), $Na_2S_2O_3 + 5H_2O$	0·024764

The following articles may be tested with this solution:

	Gm. taken.	C.c. required.	Percent. of strength indicated.
Ferri Carbonas Saccharatus	1·16	★15	★ 15 of iron.
Ferri Sulphas	1·3871	50	100 of pure salt.
Ferri Sulphas Granulatus	1·3871	50	100 of pure salt.

125. Normal Potassium Hydrate Volumetric Solution.

$KOH = 55·99$. 55·99 Gm.† in 1 Liter.

Dissolve 75 Gm. of potassium hydrate [*Potassa*, U. S. P.] in enough water to make, at or near 15° C. (59° F.), about 1050 C.c., and fill a burette with a portion of this liquid.

* Generally rounded off to 4·9 Gm., when a delicate balance and exact weights are not available.
† This figure is frequently rounded off to 56 Gm.

Put 0·6285 Gm.* of pure oxalic acid (see No. 122) into a flask of the capacity of about 100 C.c., and dissolve it with about 10 C.c. of water. Add a few drops of phenolphtalein T.S., and then carefully add, from the burette, the potassium hydrate solution, frequently agitating the flask, and regulating the flow to drops towards the end of the operation, until the red color produced by its influx no longer disappears on shaking, but is not deeper than pale pink. Note the number of C.c. of the potassium hydrate solution consumed, and then dilute the remainder of the solution so that exactly 10 C.c. of the diluted liquid shall be required to neutralize 0·6285 Gm.* of oxalic acid.

EXAMPLE.—Assuming that 8·0 C.c. of the stronger solution of potassium hydrate first prepared had been consumed in the trial, then each 8·0 C.c. must be diluted to 10 C.c., or the whole of the remaining solution in the same proportion. Thus, if 1000 C.c. should be still remaining, this must be diluted with water to 1250 C.c.

After the liquid is thus diluted, a new trial should be made in the manner above described, in which 10 C.c. of the diluted solution should exactly neutralize 0·6285 Gm.* of oxalic acid. If necessary, a new adjustment should then be made to render the correspondence perfect.

NOTE.—Solutions of caustic alkalies are very prone to absorb carbon dioxide from the atmosphere, and thereby become liable to occasion errors when used with litmus T.S. or phenolphtalein T.S. as indicator (methyl-orange T.S. is not affected by the presence of carbonic acid). Hence the volumetric solutions should be preserved in small vials provided with well-fitting corks or rubber stoppers, or, better still, they should have tubes filled with a mixture of soda and lime attached to their stoppers, so as to absorb the carbon dioxide and prevent its access to the solution.

In place of potassium hydrate V.S., sodium hydrate V.S. (see No. 132) may be used, in the same manner and in the same quantity. Potassium hydrate V.S., however, is preferable, since it foams less, and attacks glass more slowly and less energetically.

One Cubic Centimeter of Normal Potassium Hydrate V.S. is the equivalent of:

	Gramme.
Potassium Hydrate, KOH	0·05599
Sodium Hydrate, NaOH	0·03996
Ammonia Gas, NH_3	0·01701
Ammonium Chloride, NH_4Cl	0·05338
Acetic Acid, absolute, $HC_2H_3O_2$	0·05986
Citric Acid, crystallized, $H_3C_6H_5O_7 + H_2O$	0·06983
Hydrobromic Acid, absolute, HBr	0·08076
Hydrochloric Acid, absolute, HCl	0·03637
Hydriodic Acid, absolute, HI	0·12753
Hypophosphorous Acid, HPH_2O_2	0·06588
Lactic Acid, absolute, $HC_3H_5O_3$	0·08979
Nitric Acid, absolute, HNO_3	0·06289
Oxalic Acid, crystallized, $H_2C_2O_4 + 2H_2O$	0·06285
Phosphoric Acid, H_3PO_4 (to form K_2HPO_4; with phenolphtalein)	0·0489
Phosphoric Acid, H_3PO_4 (to form KH_2PO_4; with methyl-orange)	0·0978
Potassium Dichromate, $K_2Cr_2O_7$	0·14689
Sulphuric Acid, absolute, H_2SO_4	0·04891
Tartaric Acid, crystallized, $H_2C_4H_4O_6$	0·07482

The following articles are tested with this solution:

	Gm. taken.	C.c. required.		Percent. of strength indicated.
Acidum Aceticum	6·0	36·0	36	of absolute acid.
Acidum Aceticum Dilutum	24·0	24·0	6	of absolute acid.
Acidum Aceticum Glaciale	3·0	49·5	99	of absolute acid.
Acidum Citricum	3·5	50·0	100	of crystall. acid.
Acidum Hydrobromicum Dilutum	8·08	10·0	10	of absolute acid.
Acidum Hydrochloricum	3·64	31·9	31·9	of absolute acid.
Acidum Hydrochloricum Dilutum	3·64	10·0	10	of absolute acid.
Acidum Hypophosphorosum Dilutum	6·6	★10·0	★10	of absolute acid.
Acidum Lacticum	4·50	37·5	75	of absolute acid.
Acidum Nitricum	3·145	34·0	68	of absolute acid.
Acidum Nitricum Dilutum	6·29	10·0	10	of absolute acid.
Acidum Phosphoricum	0·978	17·0	85	of absolute acid.
Acidum Phosphoricum Dilutum	4·89	10·0	10	of absolute acid.
Acidum Sulphuricum	0·49	9·25	92·5	of absolute acid.
Acidum Sulphuricum Aromaticum	4·89	★18·5	★18·5	of absolute acid.
Acidum Sulphuricum Dilutum	4·89	10·0	10	of absolute acid.
Acidum Tartaricum	3·75	50·0	100	of crystall. acid.
Vinum Album	50·0	3·0 to 5·2	0·45 to 0·78	of acid assumed to be tartaric.
Vinum Rubrum				

* This figure may be rounded off to 0·63 Gm., if a delicate balance and exact weights are not available.

126. Centinormal Potassium Hydrate Volumetric Solution.

$KOH = 56{\cdot}99$. 0·5599 Gm. in 1 Liter.

Dilute 10 C.c. of normal potassium hydrate volumetric solution with enough distilled water to make 1000 C.c.

One Cubic Centimeter of Centinormal Potassium Hydrate V.S. is the equivalent of :

	Gramme.
Potassium Hydrate, KOH	0·0005599
Sulphuric Acid, H_2SO_4	0·0004891
Combined Alkaloids of Nux Vomica*	0·00364

127. Decinormal Potassium Permanganate Volumetric Solution.

$2KMnO_4 = 315{\cdot}34$. 3·1534 Gm.† in 1 Liter.

I. Place 3·5 Gm. of pure, crystallized potassium permanganate in a flask, add 1000 C.c. of boiling water, and boil until the crystals are dissolved. Close the flask, and set it aside for two days, so that any suspended matters may deposit. This is the *stronger solution*. Prepare another, *weaker solution*, in the same manner, using 6·6 Gm. of the salt and 2200 C.c. of water, and set this also aside for two days. After the lapse of this time, pour off the clear portion of each solution into separate vessels provided with glass stoppers, and then proceed to test each separately.

Introduce into a flask 10 C.c. of decinormal oxalic acid V.S., add 1 C.c. of pure, concentrated sulphuric acid, and, before this mixture cools, gradually add from a burette small quantities of the weaker permanganate solution, shaking the flask after each addition and reducing the flow to drops towards the end of the operation. When the last drop of the permanganate solution added is no longer decolorized but imparts a pinkish tint to the liquid, note the number of C.c. consumed. In the same manner ascertain the titer of the stronger solution, and likewise note down the number of C.c. of the latter consumed. Finally mix the two solutions in such proportions that 50 C.c. of the mixture will exactly correspond to an equal volume of decinormal oxalic acid V.S.

NOTE.—To obtain the accurate proportions for mixing the two solutions, deduct 10 from the number of C.c. of the weaker solution required to decompose 10 C.c. of decinormal oxalic acid V.S. With this difference multiply the number of C.c. of the stronger solution required for the same purpose. The product shows the number of C.c. of the *stronger solution* needed for the mixture.

Next deduct the number of C.c. of the stronger solution required to decompose 10 C.c. of decinormal oxalic acid V.S. from 10, and with the difference multiply the number of C.c. of the weaker solution required for the same purpose. The product shows the number of C.c. of the *weaker solution* needed for the mixture.

Or, designating by S the number of C.c. of the stronger solution, and by W the number of C.c. of the weaker solution required to decompose 10 C.c. of decinormal oxalic acid V.S., the following formula will give the proportions in which the solutions must be mixed :

Stronger Solution :		Weaker Solution :
$(W - 10)\ S$	+	$(10 - S)\ W$

EXAMPLE.—Assuming that 9 C.c. of the stronger (S) and 10·5 of the weaker (W) solution had been required, then, substituting these values in the above given formula, we obtain :

$(10{\cdot}5 - 10)\ 9 + (10 - 9)\ 10{\cdot}5$
or, 4·5 + or, 10·5

making 15 C.c. of final solution.

The bulk of the two solutions is now mixed in the same proportion, 450 C.c. of the stronger and 1050 C.c. of the weaker, or 900 C.c. of the stronger and 2100 C.c. of the weaker solution.

After the mixture is thus prepared, a new trial should be made, when 10 C.c. of the solution should exactly decompose 10 C.c. of the decinormal oxalic acid V.S. If necessary, a new adjustment should be made to render the correspondence perfect.

This solution should be kept in small, dark amber-colored and glass-stoppered bottles (or in bottles provided with tubes, especially designed for the purpose). Thus prepared, this solution will hold its titer for months ; yet it should be tested occasionally, and, when it is found reduced, the liquid should be brought back to normal strength by the addition of such an amount of the stronger solution as may be determined in the manner above described.

II. When potassium permanganate V.S. is to be prepared for immediate use, this may be done in the following manner. Dissolve 3·5 Gm. of pure, crystallized potassium permanganate in 1000 C.c. of pure water, recently boiled and cooled. Introduce 10 C.c. of decinormal oxalic acid V.S. into a beaker, add 1 C.c. of pure concentrated sulphuric acid, and proceed as directed above for the weaker permanganate solution. Note the number of C.c. of the solution consumed, and then dilute the remainder with pure water recently boiled and cooled, until 50 C.c. will exactly correspond to 50 C.c. of decinormal oxalic acid V.S.

EXAMPLE.—Assuming that 9·1 C.c. of the permanganate solution first prepared had been required to produce a permanent pink tint, then every 9·1 C.c. of the solution must be diluted to 10 C.c., or the whole of the remaining solution in the same proportion. A new trial should then be made to verify the agreement.

* Assumed to consist of equal parts of strychnine and brucine.—Centinormal potassium hydrate V.S. (in place of which centinormal sodium hydrate V.S., prepared in the same manner, may be employed) is used in the assay of Extract of Nux Vomica, to neutralize the excess of decinormal sulphuric acid employed.

† This quantity is never directly weighed, but adjusted either by Oxalic Acid or by Iron ; in calculations it is often abbreviated.

NOTE.—Potassium permanganate V.S. thus prepared is liable to deteriorate more readily and quickly than that prepared by the method first given (under I.). It cannot be safely trusted without verification, each time it is to be used.

One Cubic Centimeter of Decinormal Potassium Permanganate V.S. is the equivalent of:

	Gramme.

128. Centinormal Potassium Permanganate Volumetric Solution.

$2KMnO_4 = 315·34$. 0·31534 Gm. in 1 Liter.

Dilute 10 C.c. of the decinormal potassium permanganate V.S., after having ascertained that it possesses its exact titer, with enough distilled water strictly complying with the tests given in the text of the Pharmacopœia for *Aqua Destillata*, to make 100 C.c.

This solution should be freshly made when required.

One Cubic Centimeter of Centinormal Potassium Permanganate V.S. is the equivalent of:

	Gramme.
Potassium Permanganate, $KMnO_4$	0·00031534
Oxalic Acid, crystallized, $H_2C_2O_4 + 2H_2O$	0·0006285
Oxygen (derived from the permanganate) available for oxidation	0·0000798

129. Decinormal Potassium Sulphocyanate Volumetric Solution.

[VOLHARD'S SOLUTION.]

$KSCN = 96·99$. 9·699 Gm. in 1 Liter.

Dissolve 10 Gm. of crystals of pure potassium sulphocyanate in 1000 C.c. of water.

This solution is yet too concentrated, and has to be adjusted so as to correspond in strength exactly with decinormal silver nitrate V.S. For this purpose, introduce into a flask 10 C.c. of decinormal silver nitrate V.S. together with 0·5 C.c. of ferric ammonium sulphate T.S. and 5 C.c. of diluted nitric acid. To this mixture add, from a burette, in small portions at a time, the sulphocyanate solution. At first a white precipitate of silver sulphocyanate appears, then every drop falling from the burette is surrounded by a deep brownish-red color of ferric sulphocyanate which disappears on vigorous shaking of the flask as long as any of the silver nitrate remains unchanged. When all the silver has been converted into sulphocyanate, a single additional drop of the potassium sulphocyanate solution produces a brownish-red color which no longer disappears on shaking, but communicates a perceptible pale brownish or reddish tint to the contents of the flask. Note the number of C.c. of the potassium sulphocyanate solution used, and dilute the whole of the remaining solution so that equal volumes of this and of the decinormal silver nitrate V.S. will be required to produce the permanent brownish or reddish tint. (The same depth of pale brownish or red-

dish tint to which the volumetric solution is adjusted must be attained when the solution is used for volumetric assays.)

After the dilution, a new trial should be made, in which 50 C.c. of decinormal silver nitrate V.S., 2·5 C.c. of ferric ammonium sulphate T.S., and 25 C.c. of diluted nitric acid are used, and there should be required exactly 50 C.c. of the sulphocyanate solution to produce the same depth of a permanent pale brownish or reddish tint.

If necessary, a new adjustment should be made, to render the correspondence perfect.

One Cubic Centimeter of Decinormal Potassium Sulphocyanate V.S. is the equivalent of:

	Gramme.
Potassium Sulphocyanate, KSCN	9·009699
Silver, Ag	0·010766
Silver Nitrate, $AgNO_3$	0·016955

The following articles are tested with this solution:

Ferri Iodidum Saccharatum, Syrupus Ferri Iodidi — Determined by residual titration with decinormal silver nitrate V.S., and decinormal potassium sulphocyanate V.S.

130. Decinormal Silver Nitrate Volumetric Solution.

$AgNO_3 = 169·55$. 16·955 Gm.* in 1 Liter.

Dissolve 16·955 Gm.* of pure silver nitrate in enough water to make, at or near 15° C. (59° F.), exactly 1000 C.c.

Keep the solution in small, dark amber-colored, glass-stoppered vials, carefully protected from dust.

NOTE.—Titration by decinormal silver nitrate V.S. may be managed in various ways, adapted to the special preparation to be tested:

a. In most cases it is directed by the U. S. P. to be used in presence of a small quantity of potassium chromate T.S., which serves to indicate the end of the reaction by the appearance of the red color of silver chromate.

b. In some cases (potassium cyanide, hydrocyanic acid) it is added until the first appearance of a permanent precipitate.

c. It may be used in *all* cases without indicator by observing the exact point when no further precipitate occurs. This may be practised in the case of ferrous iodide, where the addition of potassium chromate would be improper, but it consumes much time in waiting for the precipitate to subside so as to render the liquid sufficiently clear to recognize whether a further precipitate is produced by addition of the silver solution.

d. It may be added in definite amount, known to be in excess of the quantity required, and the excess of the decinormal silver solution measured back by the addition of decinormal potassium sulphocyanate V.S. (residual titration).

One Cubic Centimeter of Decinormal Silver Nitrate V.S. is the equivalent of:

NOTE.—The articles marked with † are determined by residual titration with decinormal silver nitrate V.S. and decinormal potassium sulphocyanate V.S.

131. Decinormal Sodium Chloride Volumetric Solution.

$NaCl = 58·37$. 5·837 Gm.* in 1 Liter.

Dissolve 5·837 Gm.* of pure sodium chloride (see below) in enough water to make, at or near 15° C. (59° F.), exactly 1000 C.c.

Pure Sodium Chloride may be prepared by passing a current of dry hydrochloric acid gas into a saturated aqueous solution of the purest commercial sodium chloride, separating the crystalline precipitate, and drying it at a temperature sufficiently high to expel all traces of free acid.

In place of this, transparent crystals of pure rock salt may be employed.

One Cubic Centimeter of Decinormal Sodium Chloride V.S. is the equivalent of:

	Gramme.
Sodium Chloride, NaCl	0·005837
Silver, Ag	0·010766
Silver Nitrate, $AgNO_3$	0·016955
Silver Oxide, Ag_2O	0·011564

The following articles are tested with this solution:

	Gm. taken.	C.c. required.		Percent. of strength indicated.
Argenti Nitras	0·34	20·0	100	of silver nitrate.
Argenti Nitras Dilutus	1·0	19·5	33·14	of silver nitrate.
Argenti Nitras Fusus	0·34	19·0	95	of silver nitrate.

132. Normal Sodium Hydrate Volumetric Solution.

$NaOH = 39·96$. 39·96 Gm.† in 1 Liter.

Dissolve 54 Gm. of sodium hydrate (*Soda*, U. S. P.) in enough water to make, at or near 15° C. (59° F.), about 1050 C.c., and fill a burette with a portion of this liquid.

Put 0·6285 Gm.† of pure oxalic acid (see under No. 122) into a flask of the capacity of about 100 C.c., and dissolve it with about 10 C.c. of water. Add a few drops of phenolphtalein T.S., and then carefully add, from the burette, the sodium hydrate solution, frequently agitating the flask, and regulating the flow to drops towards the end of the operation, until the red color produced by its influx no longer disappears on shaking, but is not deeper than pale pink. Note the number of C.c. of the sodium hydrate solution consumed, and then dilute the remainder of it so that exactly 10 C.c. of the diluted liquid will be required to neutralize 0·6285 Gm.‡ of oxalic acid.

EXAMPLE.—Assuming that 7·8 C.c. of the stronger solution of sodium hydrate first prepared had been consumed in the trial, then each 7·8 C.c. must be diluted to 10 C.c., or the whole of the remaining solution in the same proportion. Thus, if 980 C.c. should be still remaining, this must be diluted with water to 1258 C.c.

After the liquid is thus diluted, a new trial should be made in the manner above described, in which 10 C.c. of the diluted solution should exactly neutralize 0·6285 Gm. of oxalic acid. If necessary, a new adjustment should then be made, to render the correspondence perfect.

NOTE.—The same precautions should be taken for protecting this solution from the carbon dioxide of the air, as are prescribed for normal potassium hydrate V.S. (see No. 125).

This solution may be employed in place of the normal potassium hydrate V.S., volume for volume.

* Frequently rounded off to 5·84 Gm., when a delicate balance and exact weights are not available.
† Frequently rounded off to 40 Gm.
‡ This may be rounded off to 0·63 Gm., when a delicate balance and exact weights are not available.

133. Decinormal Sodium Hyposulphite Volumetric Solution.

$Na_2S_2O_3 + 5H_2O = 247{\cdot}64$. 24·764 Gm. in 1 Liter.

Dissolve 30 Gm. of selected crystals of sodium hyposulphite (sodium thiosulphate) in enough water to make, at or near 15° C. (59° F.), 1100 C.c. Of this solution transfer 10 C.c. into a flask, add a few drops of starch T.S., and then gradually add, from a burette, decinormal iodine V.S., in small portions at a time, shaking the flask after each addition, and regulating the flow to drops towards the end of the operation. As soon as the color produced by the influx of the iodine solution no longer disappears on shaking, but is not deeper than very pale blue, note the number of C.c. of the iodine solution consumed. Then dilute the sodium hyposulphite solution so that equal volumes of it and of decinormal iodine V.S. will exactly correspond to each other under the conditions mentioned above.

EXAMPLE.—Assuming that 10 C.c. of the stronger sodium hyposulphite solution first prepared had required 10·7 C.c. of decinormal iodine V.S. to produce a faint reaction with starch, the hyposulphite solution must be diluted in the proportion of 10 C.c. to 10·7 C.c., or 1000 C.c. to 1070 C.c.

After the solution is thus diluted, a new trial should be made in the manner above described, in which 50 C.c. of the decinormal sodium hyposulphite V.S. should require exactly 50 C.c. of decinormal iodine V.S. to produce a faint reaction with starch. If necessary, a new adjustment should then be made to render the correspondence perfect.

Keep the solution in small, dark amber-colored, glass-stoppered bottles, carefully protected from dust.

NOTE.—When this solution is to be used, fill a burette with it, place the liquid to be tested either for the free iodine it already contains, or for that which it liberates from an excess of potassium iodide added to it, into a flask, and gradually add small portions of the solution from the burette, shaking after each addition, and regulating the flow to drops towards the end of the operation, until the brown color of the iodine has nearly disappeared. Now add a few drops of starch T.S., which will produce a blue color, and then continue to add the hyposulphite solution in drops until the blue tint is exactly discharged.

One Cubic Centimeter of Decinormal Sodium Hyposulphite V.S. is the equivalent of:

	Gramme.
Sodium Hyposulphite (Thiosulphate), $Na_2S_2O_3 + 5H_2O$	0·024764

134. Normal Sulphuric Acid.

$H_2SO_4 = 97{\cdot}82$. 48·91 Gm. in 1 Liter.

Carefully mix 30 C.c. of pure, concentrated sulphuric acid (of specific gravity 1·835) with enough water to make about 1050 C.c., and allow the liquid to cool to about 15° C. (59° F.). Place 10 C.c. of this

liquid (which is yet too concentrated) into a flask, add a few drops of phenolphtalein T.S., and afterwards, from a burette, normal potassium hydrate V.S., shaking after each addition, and regulating the flow to drops towards the end of the operation, until the red color produced by its influx no longer disappears on shaking, but is not deeper than pale pink. Note the number of C.c. of potassium hydrate consumed. Then dilute the sulphuric acid solution so that equal volumes of this and of normal potassium hydrate V.S. exactly neutralize each other.

EXAMPLE.—Assuming that 10 C.c. of the acid solution first prepared had required exactly 11·2 C.c. of normal potassium hydrate V.S., each 10 C.c. of the former must be diluted to 11·2 C.c., or each 1000 C.c. to 1120 C.c.

After the liquid is thus diluted, a new trial should be made in the manner above described, in which 50 C.c. of the acid solution should require for neutralization exactly 50 C.c. of potassium hydrate V.S. If necessary, a new adjustment should be made to render the correspondence perfect.

NOTE.—It is recommended that, in alkalimetric determinations, when an acid of normal strength is required, normal sulphuric acid be employed, in place of normal oxalic acid V.S. (see note under No. 122).

One Cubic Centimeter of Normal Sulphuric Acid is the equivalent of:

Extractum Nucis Vomicæ	0·4	*1·65	15 of total alkaloids.

IV. GASOMETRIC ESTIMATIONS.

In certain cases the Pharmacopœia directs the strength of a product or chemical substance to be determined by the volume of some gas (nitrogen dioxide) given off during a definite reaction. This volume is to be determined by the nitrometer in the following manner.

Arrange a nitrometer consisting of a measuring tube (graduated for at least 50 C.c.) and connected by stout rubber tubing with an open equilibrium tube (both tubes, preferably, provided with a globular expansion near the lower end) in such a manner, by suitable clamps attached to a stand, that either tube may be readily and quickly clamped at a higher or lower level. The stop-cock of the measuring tube having been opened, and the open equilibrium tube having been raised to a higher level, pour into the latter a saturated aqueous solution of sodium chloride, until the measuring tube, including the bore of the stop-cock, is completely filled. Then close the latter and fix the equilibrium tube at a low level. Having ascertained that the stop-cock is closed air-tight, and having, if necessary, wiped out the graduated funnel tube of the nitrometer, introduce into it the prescribed quantity of the liquid to be tested, and allow this to flow slowly into the measuring tube, being careful not to admit any air. Follow it by the prescribed quantities of the several reagents (potassium iodide T.S., and normal sulphuric acid). When the reaction, which takes place at once, moderates, remove the measuring tube from its clamp, and, being careful to hold it constantly so that the liquid contained in it stands at a higher level than that in the equilibrium tube, shake its contents, without permitting any gas to pass into the open tube. When the reaction has completely ceased, restore the tube to its fastening, and allow the apparatus and contents to acquire the ordinary temperature of the room, which is assumed to be at or about 25° C. (77° F.). Then adjust the two tubes so that the liquid columns are at exactly the same level, and read off the volume of gas in the measuring tube. Multiply this figure by the weight of the substance yielding 1 C.c. of nitrogen dioxide (see below). The result will be the weight of the pure substance (nitrite) contained in the amount taken for the assay.

For pharmacopœial purposes the determination will be sufficiently exact if the evolved gas be measured at or near 25° C. (77° F.). If it be desired to ascertain the volume which the gas would occupy at any other temperature between 0° C. and 40° C. (32°–104° F.), this may be done with the aid of the table below printed.

EXAMPLE.—Assuming that the volume of gas read off was 44·5 C.c. at 27° C. (80·6° F.), and that it be desired to ascertain the corresponding volume at 0° C. (32° F.), barometric pressure not being taken into consideration, then the 44·5 C.c. must be reduced in the proportion of 1·098901 to 1; or 44·5 must be divided by 1·098901. The result will be 40·5 C.c.

The following table shows the expansion which *one* (1) *cubic centimeter* of a gas will undergo when it is raised from 0° C. (32° F.) to 40° C. (104° F.).

Expansion of 1 Cc. of a Gas, between 0° and 40° C.

°C.	C.c.	°C.	C.c.	°C.	C.c.
0	1·000000	14	1·051282	28	1·102564
1	1·003663	15	1·054945	29	1·106227
2	1·007326	16	1·058608	30	1·109890
3	1·010989	17	1·062271	31	1·113553
4	1·014652	18	1·065934	32	1·117216
5	1·018315	19	1·069597	33	1·120879
6	1·021978	20	1·073260	34	1·124542
7	1·025641	21	1·076923	35	1·128205

13	1·047619	27	1·098901		

* To be determined to at least 2 decimals by titrating the uncombined acid with centinormal potassium hydrate V.S.

136. Estimation of Nitrogen Dioxide.

NO = 29·97; 1 Liter { at 0° C. and 760 Mm. = 1·3423 Gm.
at 25° C. and 760 Mm. = 1·2297 Gm.

One Cubic Centimeter of Nitrogen Dioxide is the equivalent of:

	At 0° C. and 760 Mm. Gramme.	At 25° C. and 760 Mm. Gramme.
Nitrogen Dioxide, NO = 29·97	0·0013423	0·0012297
Amyl Nitrite, $C_5H_{11}NO_2$ = 116·78	0·0052305	0·0047923
Ethyl Nitrite, $C_2H_5NO_2$ = 74·87	0·0033529	0·0030716
Sodium Nitrite, $NaNO_2$ = 68·93	0·0030873	0·0028283

The following articles are tested gasometrically by the volume of Nitrogen Dioxide evolved and measured at or near 25° C. (77° F.).

	Amount taken.	Volume of NO.	Strength indicated.
Amyl Nitris	0·26 Gm.*	★40 C.c.	★80% of pure amyl nitrite.
Sodii Nitris	0·15 "	50 C.c.	97.6% of pure salt.
Spiritus Ætheris Nitrosi (fresh)	5 C.c.	55 C.c.	★ 4% of pure ethyl nitrite

V. ALKALOIDAL ASSAY BY IMMISCIBLE SOLVENTS.

It is a property of many alkaloids that they are soluble in certain liquids in which their salts are insoluble, while in other liquids the case is reversed. When such liquids are not miscible, the conditions are favorable to what has been called the "shaking-out" process of separation. In many cases the extraction or separation may be effected by shaking together the concentrated aqueous extract, to which a suitable alkaline precipitant has been added, and some solvent, such as chloroform, ether, benzin, benzol, amyl alcohol, etc. The precipitated alkaloid is thus washed out of the aqueous solution, and is dissolved by the chloroform or other immiscible liquid employed. From the solution of the alkaloid thus obtained, the latter may again be abstracted by a dilute acid. In this Pharmacopœia the only liquid which is directed as solvent for alkaloids in such assays is *chloroform*. The extraction is directed to be performed in a glass separator or separatory funnel, which consists of an elongated (globular, cylindrical, or conical) glass vessel, provided with a well-fitting stopper and an outlet-tube containing a well-ground glass stop-cock.

When the solution of an alkaloid, suitably prepared, is introduced into this vessel, and chloroform subsequently added, the latter, owing to its higher specific gravity, will form the lower layer. If the two layers are violently shaken together, there will often result an emulsion, which will separate only slowly, and often imperfectly. This is particularly liable to happen when the aqueous liquid containing the alkaloid either in suspension or in solution is strongly alkaline, and when it has a high specific gravity. To avoid the formation of an emulsion, the extraction should be accomplished rather by rapid rotation and frequent inversion of the separator than by violent shaking. When an emulsion has formed, its separation may be promoted by the addition of more of the solvent, preferably somewhat heated, aided, if necessary, by the external application of a gentle heat (the stopper being removed for the time being), or by the introduction of a small quantity of alcohol or of hot water. The separation of the two layers may also be promoted by stirring the lower, chloroformic layer with a glass rod and detaching from the walls of the separator the adhering drops of emulsion.

On withdrawing the chloroform solution of an alkaloid from the separator, a small amount of the solution will generally be retained in the outlet-tube by capillary attraction. If this were lost, the results of the assay would be seriously vitiated. To avoid this loss, several successive, small portions of chloroform should be poured into the separator without agitation, and drawn off through the stop-cock to wash out the outlet-tube.

Another source of loss is the pressure sometimes generated in the separator by the rise of temperature caused when an alkaline and an acid liquid are shaken together. On loosening the stopper, the liquid which adheres to the juncture of the latter with the neck is liable to be ejected. This is best avoided by mixing the liquids at first by rotation (avoiding contact of the contents with the stopper), and allowing them to become cold before stoppering the separator.

The same precautions should be observed when an alkali carbonate has been used, in place of a caustic alkali, for setting free the alkaloid. In this case the liquids should be cautiously and gradually mixed by rotation, and the separator should be left unstoppered until gas is no longer given off.

If a regular glass separator is not available, an ordinary burette, stoppered with a sound cork, may be employed in its place. In this case the quantities of the alkaloidal solution and of the volatile solvent must be adjusted to the size of the burette.

* This quantity will, theoretically, yield a little more than 40 C.c. of the gas; but there will be a slight loss, as the gas is somewhat soluble in the liquid.

VI. DETERMINATION OF THE OPTICAL ROTATION OF ORGANIC SUBSTANCES.

Many organic substances either liquid by nature or in solution in suitable solvents, when examined in a specially constructed polarizing apparatus or polaristrobometer, exhibit the property of circular polarization, or, in other words, are capable of rotating the plane of polarization of a ray of light either to the right or to the left. Such substances are termed "optically active," and when rotating to the right are designated as "dextro-rotatory" or "dextrogyrate," and when rotating to the left, as "lævo-rotatory" or "lævogyrate." Substances which do not possess this property of optical rotation are termed "optically inactive."

Among the substances recognized by this Pharmacopœia, there are several, particularly certain essential or volatile oils, and related bodies, for which the determination of the angle of rotation of a ray of polarized light, or, in some cases, the proof of their optical inactivity, affords the most simple and positive evidence of their identity or purity.

The instruments used for this purpose vary somewhat in their construction. Those which are most generally adapted for the examination of the substances mentioned above are the Polaristrobometer of Wild, in which the optical activity of the substance is manifested by the appearance or disappearance of dark, parallel stripes, or the so-called "half-shadow" instrument of Laurent, in which the two sides of the field of vision are capable of becoming unequally illuminated. Both of the instruments permit the angle of rotation to be read off in degrees or fractions of a degree of a circle.

These optical determinations are best made in a dark room, and by means of homogeneous or monochromatic light, the latter being obtained by introducing into a non-luminous flame, on a loop of platinum wire, a small bead of fused sodium chloride. The light thus radiated corresponds with the line D of the solar spectrum.

Since the deviation of the plane of polarization either to the right or to the left of the zero point is directly proportional to the length of the column of liquid, it is important that the observations should be made with tubes of a definite length, such as 100, 50, or 25 Mm. The selection of the length of the tube to be employed is, however, usually dependent upon the depth of color of the liquid and the extent of its optical rotation.

The rotatory power of an optically active, liquid substance, observed with sodium light, and referred to the ideal density 1, and in a tube having a length of 1 decimeter (100 Mm.), is designated as its *specific rotatory power*. This is usually expressed by the term $[\alpha]_D$. Since, however, not only the density of an optically active liquid, but also its rotation, is influenced by the temperature, the specific rotation varies with the latter. In stating the specific rotation it is, therefore, necessary to indicate at what temperature the rotation and the density of the liquid have been determined. But for the same temperature the specific rotation of a pure, optically active liquid is always a constant number.

For calculating the specific rotatory power of an optically active liquid substance, or solution of an optically active solid, the following formulas are of general application:

I. For liquid substances $$[\alpha]_D = \frac{100 \times a}{L \times d}$$

II. For solutions of solids $$[\alpha]_D = \frac{10000 \times a}{L \times p \times d}$$

or $$[\alpha]_D = \frac{10000 \times a}{L \times c}$$

For calculating these formulas the determination of the following factors is necessary:

a = the angle of rotation of the liquid or solid observed with sodium light.

L = the length of the tube in millimeters.

d = the density or specific gravity of the active liquid.

p = the amount of active substance in 100 parts by weight of the solution.

c = the number of grammes of active substance in 100 cubic centimeters of the solution.

ARTICLES EMPLOYED IN CHEMICAL TESTING AND TEST-SOLUTIONS OF THE BRITISH PHARMACOPŒIA.

The British test-solutions here given are used for determining the character of particular substances, whether isolated or in composition; thus enabling us to ascertain the identity of medicines, their purity or impurity, and the character of the foreign ingredients, which may be mixed with them accidentally, or with a view to adulteration.

Acetic Acid. "The Acetic Acid of the British Pharmacopœia." *Br.*

Acetic Acid, Glacial. "The Glacial Acetic Acid of the British Pharmacopœia." *Br.*

Albumen. "The liquid white, separated from the yolk, of the egg of Gallus Bankiva, var. domesticus, Temminck." *Br.*

Alcohol, Absolute. "The Absolute Alcohol of the British Pharmacopœia." *Br.*

Alcohol (90 per cent.). **Alcohol** (70 per cent.). "The Alcohol (90 per cent.) and Alcohol (70 per cent.) of the British Pharmacopœia." *Br.*

Alum. "The Alum of the British Pharmacopœia." *Br.*

Ammonium Molybdate. "A nearly white crystalline salt, $(NH_4)_2MoO_4$." *Br.*

Ammonium Oxalate. "Colorless crystals, $(COONH_4)_2,H_2O$, prepared by neutralizing oxalic acid with solution of ammonia." *Br.*

Ammonium Thiocyanate. "A crystalline salt, NH_4SCN." *Br.*

Amylic Alcohol. "A liquid consisting principally of iso-primary amylic alcohol, $(CH_3)_2$: $CH.CH_2.CH_2OH$. It may be prepared by shaking commercial fusel oil with a saturated solution of common salt, separating the oily layer, submitting it to distillation, and collecting and reserving the portion which distils between 257° and 289° F. (125° and 142·8° C.)." *Br.*

Barium Chloride. "Colorless crystals, $BaCl_2,2H_2O$. Its solution should not give a precipitate with solution of ammonium hydrosulphide, and no residue should remain after adding excess of diluted sulphuric acid, filtering, and evaporating the filtrate to dryness in a platinum dish. Barium nitrate, $Ba2NO_3$, or barium acetate, $(CH_3COO)_2Ba$, may be used in place of barium chloride, but each must respond to the foregoing tests." *Br.*

Barium Hydroxide. "Colorless crystals, $Ba(OH)_2,8H_2O$, prepared by mixing concentrated solutions of barium chloride and sodium hydroxide. The precipitate is purified by recrystallization from water. It should be entirely soluble in water, the resulting solution should give no precipitate with solution of ammonium hydrosulphide, and a very slight residue should remain after adding excess of diluted sulphuric acid, filtering, and evaporating the filtrate to dryness in a platinum dish." *Br.*

Benzol. "The Benzol of the British Pharmacopœia." *Br.*

Benzolated Amylic Alcohol. "Benzol, 3 parts by volume; Amylic Alcohol, 1 part by volume. Mix; decant from any deposited water." *Br.*

Bismuth Oxynitrate. "The Bismuth Oxynitrate of the British Pharmacopœia." *Br.*

Borax. "The Borax, $Na_2B_4O_7,10H_2O$, of the British Pharmacopœia." *Br.*

Bromine. "The Bromine of commerce." *Br.*

Cadmium Iodide. "The pure crystals, CdI_2, of commerce." *Br.*

Calcium Carbonate. "The pure white marble, or calc-spar, of commerce." *Br.*

Calcium Hydroxide. "The Calcium Hydroxide of the British Pharmacopœia." *Br.*

Calcium Oxide. "The Lime of the British Pharmacopœia." *Br.*

Calcium Sulphate. "Pure native calcium sulphate, $CaSO_42H_2O$." *Br.*

Carbon Bisulphide. "The Carbon Bisulphide of the British Pharmacopœia." *Br.*

Chloroform. "The Chloroform of the British Pharmacopœia." *Br.*

Citric Acid. "The Citric Acid of the British Pharmacopœia." *Br.*

Collodion. "The Collodion of the British Pharmacopœia." *Br.*

Copper. "The metal in foil, wire, or turnings." *Br.*

Copper Oxyacetate. "The pure copper oxyacetate, or verdigris, of commerce." *Br.*

Copper Sulphate. "The Copper Sulphate of the British Pharmacopœia." *Br.*

Ether. "The Ether of the British Pharmacopœia." *Br.*

Ferric Chloride. "The pure anhydrous ferric chloride of commerce." *Br.*

Ferrous Sulphate. "The Ferrous Sulphate of the British Pharmacopœia." *Br.*

Glycerin. "The Glycerin of the British Pharmacopœia." *Br.*

Hydrochloric Acid. "The Hydrochloric Acid of the British Pharmacopœia." *Br.*

Hydrochloric Acid, Diluted. "The Diluted Hydrochloric Acid of the British Pharmacopœia." *Br.*

Hydrochloric Acid, Gaseous. "The dry gas, HCl, prepared by the interaction of sulphuric acid and common salt." *Br.*

Hydrogen Sulphide. Synonym—*Sulphuretted Hydrogen.* "A gas prepared by the action of hydrochloric acid on ferrous sulphide. It will be sufficiently pure after passing through two wash-bottles each containing water. A solution of the gas in water may also be employed, but only if it smells strongly of the gas and yields an abundant black precipitate with solution of lead subacetate." *Br.*

Indigo. "A blue pigment prepared from various species of Indigofera, Linn." *Br.*

Iron. "The Iron of the British Pharmacopœia." *Br.*

Isinglass. "The swimming bladder, or sound, of various species of Acipenser, Linn., prepared and cut into shreds." *Br.*

Lead Acetate. "The Lead Acetate of the British Pharmacopœia." *Br.*

Lead Peroxide. "The pure lead peroxide, PbO_2, of commerce." *Br.*

Lime. "The Lime of the British Pharmacopœia." *Br.*

Litmus. "A blue pigment prepared from various species of Roccella, DC. Litmus is used in

several forms. For example, Solution of Litmus [page 1861]; Blue Litmus Paper, made by impregnating unglazed white paper with a solution of litmus; and Red Litmus Paper, made by impregnating the paper with the solution reddened by the previous addition of a very minute quantity of sulphuric acid. Litmus may also be employed in the solid form." *Br.*

Manganese Peroxide. "The powdered native peroxide, MnO_2, pyrolusite." *Br.*

Methyl-Orange. "Methyl-orange, $NaO.SO_2.C_6H_4N : N.C_6H_4N(CH_3)_2$, or helianthin, is prepared by the combination of diazobenzenesulphonic acid and dimethylaniline in an alkaline solution. Its warm aqueous solution should give no precipitate with an alkali or with solution of calcium chloride, but an orange-yellow precipitate with solution of lead subacetate." *Br.*

Microcosmic Salt. "The salt, $NaNH_4HPO_4,4H_2O$, of commerce." *Br.*

Milk of Lime. "Lime, 100 grammes; Distilled water, 200 cubic centimetres. Mix." *Br.*

Morphinated Water. "Prepared by digesting pure morphine in Chloroform Water for seven days at a temperature of 60° F. (15·5° C.), with occasional agitation, so as to obtain a saturated solution of the alkaloid, and filtering from the undissolved morphine." *Br.*

Morphine. "The precipitate obtained on adding solution of ammonia, in slight excess, to a solution of a pure morphine salt in water, the precipitate being washed with water until free from ammonium salt." *Br.*

Mucilage of Gum Acacia. "The Mucilage of Gum Acacia of the British Pharmacopœia." *Br.*

Mucilage of Starch. "Triturate 1 gramme of Starch with a small quantity of Distilled Water to form a smooth paste; add more Distilled Water, gradually, to produce 50 cubic centimetres of mixture; boil for a few minutes, constantly stirring; cool. Mucilage of Starch should be recently prepared." *Br.*

Nitric Acid. "The Nitric Acid of the British Pharmacopœia." *Br.*

Nitric Acid, Diluted. "The Diluted Nitric Acid of the British Pharmacopœia." *Br.*

Nitric Acid, Fuming. "Nitric Acid of specific gravity 1·5." *Br.*

Oil of Turpentine. "The Oil of Turpentine of the British Pharmacopœia." *Br.*

Olive Oil. "The Olive Oil of the British Pharmacopœia." *Br.*

Petroleum Spirit. Synonym—*Petroleum Ether.* "A colorless, very volatile, and highly inflammable liquid obtained from petroleum, and consisting of a mixture of the lower members of the paraffinic series of hydrocarbons. Boiling point 122° to 140° F. (50° to 60° C.). Specific gravity 0·670 to 0·700." *Br.*

Phenol. "The Phenol of the British Pharmacopœia." *Br.*

Phenol-Phthalein. "A crystalline substance produced by interaction of phenol and phthalic anhydride. $C\begin{cases} C_6H_4.OH \\ C_6H_4.OH \\ C_6H_4.CO \end{cases}O$." *Br.*

Picric Acid. "Trinitrophenol, $C_6H_2(NO_2)_3OH$, obtained by the action of nitric acid on phenol." *Br.*

Potassium Bichromate. "The Potassium Bichromate of the British Pharmacopœia." *Br.*

Potassium Chlorate. "The Potassium Chlorate of the British Pharmacopœia." *Br.*

Potassium Chromate. "The pure, neutral, yellow crystals, K_2CrO_4, of commerce." *Br.*

Potassium Cyanide. "The commercial salt, containing at least 90 per cent. of potassium cyanide, KCN." *Br.*

Potassium Ferricyanide. "The red crystalline salt, $K_6Fe_2C_{12}N_{12}$. Its aqueous solution should give no precipitate or blue coloration with a dilute solution of a pure ferric salt." *Br.*

Potassium Ferrocyanide. "The yellow crystalline salt, $K_4FeC_6N_6,3H_2O$, prepared by fusing together potassium carbonate, nitrogenous organic matter, and iron." *Br.*

Potassium Hydrogen Sulphite. Synonym—*Acid Potassium Sulphite.* "The commercial salt, $KHSO_3$." *Br.*

Potassium Hydroxide. "The Caustic Potash of the British Pharmacopœia." *Br.*

Potassium Iodide. "The Potassium Iodide of the British Pharmacopœia." *Br.*

Potassium Permanganate. "The Potassium Permanganate of the British Pharmacopœia." *Br.*

Potassium Sulphate. "The Potassium Sulphate of the British Pharmacopœia." *Br.*

Powdered Talc. "A natural magnesium silicate, powdered, and purified by boiling with diluted hydrochloric acid, washing with distilled water until neutral to litmus, and drying." *Br.*

Sodium Acetate. "The pure commercial salt, $CH_3COONa,3H_2O$." *Br.*

Sodium Arsenate. "The Sodium Arsenate of the British Pharmacopœia." *Br.*

Sodium Bicarbonate. "The Sodium Bicarbonate of the British Pharmacopœia." *Br.*

Sodium Carbonate. "The Sodium Carbonate of the British Pharmacopœia." *Br.*

Sodium Chloride. "The Sodium Chloride of the British Pharmacopœia." *Br.*

Sodium Hydrogen Sulphite. Synonym—*Acid Sodium Sulphite.* "The commercial salt, $NaHSO_3$." *Br.*

Sodium Hydroxide. "The sodium hydroxide, sodium hydrate, or 'caustic soda,' of commerce, occurs in hard grayish-white rods or cakes, deliquescent, very alkaline and corrosive. It affords the reactions characteristic of sodium. It usually contains as impurities alumina, carbonates, chlorides, phosphates, silicates, and sulphates. A clear solution of caustic soda may be used, instead of a solution of Purified Sodium Hydroxide, in all analytical operations in which the foregoing impurities would not vitiate the result. Purified Sodium Hydroxide may be obtained by dissolving caustic soda in ethylic alcohol, filtering the solution, evaporating it to dryness in a silver dish, occasionally adding distilled water during the evaporation. The residue is Purified Sodium Hydroxide. It should yield no characteristic reaction with the tests for phosphates or sulphates, and not more than the slightest reactions with the tests for carbonates. It is not quite free from alumina. Pure Sodium Hydroxide may be prepared by the interaction of pure barium hydroxide and sodium sulphate, or by the interaction of pure sodium and water. A solution of Pure Sodium Hydroxide is required only in testing for small quantities of aluminium." *Br.*

Sodium Nitrite. "The Sodium Nitrite of the British Pharmacopœia." *Br.*

Sodium Potassium Tartrate. "The Sodium Potassium Tartrate of the British Pharmacopœia." *Br.*

Sodium Sulphate. "The Sodium Sulphate of the British Pharmacopœia." *Br.*

Sodium Sulphite. "The Sodium Sulphite of the British Pharmacopœia." *Br.*

Sodium Thiosulphate. Synonym—*Sodium Hyposulphite.* "The crystalline salt, $Na_2S_2O_3,5H_2O$. 2·4644 grammes should decolorize 100 cubic centimetres of the volumetric solution of iodine." *Br.*

Sulphur. "The Sublimed Sulphur of the British Pharmacopœia." *Br.*

Sulphuric Acid. "The Sulphuric Acid of the British Pharmacopœia." *Br.*

Sulphuric Acid, Diluted. "The Diluted Sulphuric Acid of the British Pharmacopœia." *Br.*

Tartaric Acid. "The Tartaric Acid of the British Pharmacopœia." *Br.*

Test Papers. "See 'Litmus' and 'Turmeric.'" *Br.*

Tin. "Tin, granulated by letting drops of it in the molten state fall into water. It should yield no reactions with the tests for lead, copper, iron, or zinc." *Br.*

Turmeric. "The dried rhizome of Curcuma longa, Linn. Turmeric is commonly used in the form of tincture prepared from the bruised rhizome, in the proportion of 1 gramme to 6 cubic centimetres of Alcohol (90 per cent.), by the process of maceration or in the form of paper prepared by steeping unglazed white paper in the tincture and drying." *Br.*

Uranium Nitrate. "The crystals of pure uranium nitrate of commerce." *Br.*

Water. "The Distilled Water of the British Pharmacopœia." *Br.*

Zinc. "The laminated or granulated metal. It should be entirely dissolved by diluted hydrochloric acid. The solution should yield no characteristic reaction with the tests for lead, copper, cadmium, arsenium, tin, and iron." *Br.*

TEST-SOLUTIONS.

Solution of Albumen. "Albumen, 2 cubic centimetres; Distilled Water, 8 cubic centimetres, or a sufficient quantity. Mix by trituration in a mortar, and filter through clean tow first moistened with Distilled Water. Solution of Albumen must be recently prepared. The strength of the Solution may be adjusted to suit particular requirements." *Br.*

Solution of Ammonia. "The Solution of Ammonia of the British Pharmacopœia." *Br.*

Solution of Ammonia, Strong. "The Strong Solution of Ammonia of the British Pharmacopœia." *Br.*

Solution of Ammonium Acetate. "The Solution of Ammonium Acetate of the British Pharmacopœia." *Br.*

Solution of Ammonium Carbonate. "Ammonium Carbonate, in small pieces, 10 grammes; Solution of Ammonia, 15 cubic centimetres; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Ammonium Chloride. "Ammonium Chloride, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Ammonium Chloride (Nessler's). "Ammonium Chloride, 3·15 grammes; Distilled Water, recently boiled, and free from ammonia, sufficient to produce 1000 cubic centimetres. Dissolve." *Br.*

Solution of Ammonium Citrate. "The Solution of Ammonium Citrate of the British Pharmacopœia." *Br.*

Solution of Ammonium Hydrosulphide. "Saturate one hundred and twenty cubic centimetres of Solution of Ammonia with washed Hydrogen Sulphide; add eighty cubic centimetres of Solution of Ammonia. The Solution should be freshly prepared." *Br.*

Solution of Ammonium Molybdate. "Ammonium Molybdate, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Ammonium Oxalate. "Ammonium Oxalate, 5 grammes; Distilled Water, warm, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Ammonium Thiocyanate. "Ammonium Thiocyanate, 5 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Auric Chloride. "Pure Gold of commerce, in leaf, 1 gramme; Nitric Acid, 1.5 cubic centimetres; Hydrochloric Acid, 7 cubic centimetres; Distilled Water, a sufficient quantity. Place the Gold in a flask with the Nitric Acid and six cubic centimetres of the Hydrochloric Acid, first mixed with four cubic centimetres of the Distilled Water, and digest until it is dissolved. Add one cubic centimetre of Hydrochloric Acid. Evaporate in a basin at a temperature not exceeding 212° F. (100° C.) until acid vapors cease to be given off. Dissolve the auric chloride thus obtained in fifty cubic centimetres of Distilled Water." *Br.*

Solution of Barium Chloride. "Barium Chloride, in crystals, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Barium Hydroxide. "Barium Hydroxide, 10 grammes; Distilled Water, recently boiled, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Boric Acid. "Boric Acid, 5 grammes; Alcohol (90 per cent.), sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Bromine. "Bromine, 1 cubic centimetre; Distilled Water, sufficient to produce 150 cubic centimetres. Place the Bromine in a bottle furnished with a well-fitting stopper, and pour in the Distilled Water; shake several times. Keep the Solution in a dark place." *Br.*

Solution of Cadmium Iodide. "Cadmium Iodide, 5 grammes; Distilled Water, sufficient to produce 100 cubic centimetres. Dissolve and filter." *Br.*

Solution of Calcium Chloride. "Calcium Chloride, fused, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Calcium Sulphate. "Calcium Sulphate, 2·5 grammes; Distilled Water, 200 cubic centimetres. Rub the Calcium Sulphate in a porcelain mortar for a few minutes with twenty cubic centimetres of the Distilled Water; shake the mixture thus obtained with the rest of the Distilled Water; set aside; filter." *Br.*

Solution of Chlorinated Soda. "The Solution of Chlorinated Soda of the British Pharmacopœia." *Br.*

Solution of Chlorine. "Produced by saturating Distilled Water with chlorine. The chlorine may be obtained by the interaction of Hydrochloric Acid and Manganese Peroxide, and should be purified by passing through a small quantity of water contained in a wash-bottle. The solution should be recently prepared." *Br.*

Solution of Chromic Acid. "The Solution of Chromic Acid of the British Pharmacopœia." *Br.*

Solution of Copper Acetate. "Copper Oxyacetate, in fine powder, 20 grammes; Acetic Acid, 40 cubic centimetres; Distilled Water, sufficient to produce 200 cubic centimetres. Dilute the Acetic Acid with twenty cubic centimetres of the Distilled Water; digest the Copper Oxyacetate in the mixture at a temperature not exceeding 212° F. (100° C.), with repeated stirring; continue heating until a dry residue is obtained. Digest the product in one hundred and sixty cubic centimetres of boiling Distilled Water; make up the required volume with Distilled Water; filter." *Br.*

Solution of Copper Ammonio-Sulphate. "Copper Sulphate, in crystals, 10 grammes; Solution of Ammonia, a sufficient quantity; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve the Copper Sulphate in one hundred and sixty cubic centimetres of the Distilled Water, and cautiously add the Solution of Ammonia to the liquid until the precipitate first formed is nearly dissolved; filter the product; finally make up the required volume with Distilled Water. A concentrated solution may be prepared by using a smaller quantity of Distilled Water." *Br.*

Solution of Copper Sulphate. "Copper Sulphate, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve, and filter if necessary." *Br.*

Solution of Ferric Chloride. "See 'Test-Solution of Ferric Chloride' [page 1862]." *Br.*

Solution of Ferric Sulphate. "The Solution of Ferric Sulphate of the British Pharmacopœia." *Br.*

Solution of Ferrous Sulphate. "Ferrous Sulphate, 4 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter. The solution of Ferrous Sulphate should be recently prepared." *Br.*

Solution of Hydrogen Peroxide. "The Solution of Hydrogen Peroxide of the British Pharmacopœia." *Br.*

Solution of Indigo Sulphate. "Indigo, dry and in fine powder, 0·2 gramme; Sulphuric Acid, 200 cubic centimetres. Mix the Indigo with two cubic centimetres of the Sulphuric Acid in a small test-tube, and heat in boiling water for an hour; pour the product into the remainder of the acid; shake the mixture; decant the clear liquid." *Br.*

Solution of Iodine. "The Volumetric Solution of Iodine [page 1867]." *Br.*

Solution of Isinglass. "Isinglass, in shreds, 4 grammes; Distilled water, warm, sufficient to produce 200 cubic centimetres. Mix, and digest for half an hour on a water-bath with repeated shaking, and filter through clean moistened tow. Solution of Isinglass must be recently prepared." *Br.*

Solution of Lead Acetate. "Lead Acetate, 20 grammes; Distilled Water, recently boiled, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Lead Subacetate. "The Strong Solution of Lead Subacetate of the British Pharmacopœia; or the same, more or less diluted." *Br.*

Solution of Lime. Synonym—*Solution of Calcium Hydroxide.* "The Solution of Lime of the British Pharmacopœia." *Br.*

Solution of Litmus. "Litmus, in powder, 20 grammes; Alcohol (90 per cent.), 200 cubic centimetres; Distilled Water, 200 cubic centimetres. Boil the Litmus with eighty cubic centimetres of the Alcohol for one hour; pour away the clear liquid; repeat this operation with sixty cubic centimetres of the Alcohol; and a third time with the remainder of the Alcohol. Digest the washed Litmus in the Distilled Water, and filter." *Br.*

Solution of Magnesium Ammonio-Sulphate. "Magnesium Sulphate, 20 grammes; Ammonium Chloride, 40 grammes; Solution of Ammonia, 84 cubic centimetres; Distilled Water, 160 cubic centimetres. Dissolve the Magnesium Sulphate and Ammonium Chloride in the Distilled Water; add the Solution of Ammonia, and set the mixture aside for a few days in a well-closed bottle; decant and filter." *Br.*

Solution of Magnesium Sulphate. "Magnesium Sulphate, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Mercuric Chloride. "See 'Test-Solution of Mercuric Chloride' [page 1862]." *Br.*

Solution of Mercurous Nitrate. "Mercury, 2 grammes; Nitric Acid, 1 cubic centimetre; Distilled Water, a sufficient quantity. To the Mercury, in a small dish, add one cubic centimetre of Distilled Water and the Nitric Acid, and set the whole aside for twenty-four hours in a cool dark place; drain the resulting crystals; dissolve them in two hundred cubic centimetres of Distilled Water." *Br.*

Solution of Methyl Orange. "Methyl Orange, 0.4 gramme; Alcohol (90 per cent.), 50 centimetres; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve." *Br.*

Solution of Phenol-Phthalein. "Phenol-phthalein, 0.4 gramme; Alcohol (90 per cent.), 120 cubic centimetres; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve. The Solution should be colorless." *Br.*

Solution of Picric Acid. "Picric Acid, 1 gramme; Distilled Water, sufficient to produce 150 cubic centimetres. Dissolve." *Br.*

Solution of Platinic Chloride. "Platinum foil of commerce, 10 grammes; Hydrochloric Acid, 60 cubic centimetres; Nitric Acid, 10 cubic centimetres; Distilled Water, sufficient to produce 200 cubic centimetres. Heat the Platinum foil with the Hydrochloric Acid to about 176° F. (80° C.); add the Nitric Acid very gradually; evaporate the solution to dryness on a water-bath; moisten the residue with a few drops of Hydrochloric Acid; again evaporate to dryness; dissolve the residue in sufficient Distilled Water to produce two hundred cubic centimetres of the Solution." *Br.*

Solution of Potassio-Cupric Tartrate. Synonym—*Fehling's Solution.*

"No. 1. Copper Sulphate, in crystals, 34.64 grammes; Sulphuric Acid, 0.5 cubic centimetre; Distilled Water, sufficient to produce 500 cubic centimetres. Dissolve.

"No. 2. Sodium Potassium Tartrate, 176 grammes; Sodium Hydroxide, 77 grammes; Distilled Water, sufficient to produce 500 cubic centimetres. Dissolve. Mix equal volumes of the solutions No. 1 and No. 2 at the time of using." *Br.*

Solution of Potassio-Mercuric Iodide. Synonym.—*Nessler's Reagent.* "Potassium Iodide, 7 grammes; Mercuric Chloride, a sufficient quantity; Sodium Hydroxide, 24 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve the Potassium Iodide and two and a half grammes of Mercuric Chloride in one hundred and sixty cubic centimetres of Distilled Water; to this liquid add a cold saturated aqueous solution of Mercuric Chloride, with constant stirring, until a slight red precipitate remains; add the Sodium Hydroxide; when the latter has dissolved add a little more of the aqueous solution of Mercuric Chloride, and make up the required volume with Distilled Water." *Br.*

Solution of Potassium Acetate. "Potassium Acetate, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Potassium Acid Tartrate. "Digest excess of Acid Potassium Tartrate in Distilled Water; filter." *Br.*

Solution of Potassium Carbonate. "Potassium Carbonate, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Potassium Chromate. "Potassium Chromate, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Potassium Cyanide. "Potassium Cyanide, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Potassium Ferricyanide. "Potassium Ferricyanide, in crystals, 10 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter. This Solution should be freshly prepared." *Br.*

Solution of Potassium Ferrocyanide. "Potassium Ferrocyanide, in crystals, 10 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Potassium Hydroxide. "The Solution of Potash of the British Pharmacopœia." *Br.*

Solution of Potassium Hydroxide, Alcoholic. "Potassium Hydroxide, 20 grammes; Alcohol (90 per cent.), sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Potassium Iodide. "Potassium Iodide, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Potassium Permanganate. "The Solution of Potassium Permanganate of the British Pharmacopœia." *Br.*

Solution of Pyroxylin. "The Collodion of the British Pharmacopœia." *Br.*

Solution of Silver Ammonio-Nitrate. "Silver Nitrate, in crystals, 5 grammes; Solution of Ammonia, 10 cubic centimetres, or a sufficient quantity; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve the Silver Nitrate in one hundred and sixty cubic centimetres of the Distilled Water, and cautiously add the Solution of Ammonia to the liquid until the precipitate first formed is nearly dissolved; set aside; decant; finally make up the required volume with Distilled Water." *Br.*

Solution of Silver Nitrate. "Silver Nitrate, 10 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve." *Br.*

Solution of Sodium Acetate. "Sodium Acetate, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Sodium Carbonate. "Sodium Carbonate, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Sodium Hydroxide. "Purified Sodium Hydroxide, 40 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Sodium Phosphate. "Sodium Phosphate, in crystals, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Sodium Sulphate. "Sodium Sulphate, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Stannous Chloride. "Tin, granulated, 40 grammes; Hydrochloric Acid, 120 cubic centimetres; Distilled Water, sufficient to produce 200 cubic centimetres. Dilute the Acid in a flask with forty cubic centimetres of the Distilled Water, and, having added the Tin, apply heat gently until gas ceases to be evolved; make up the required volume with Distilled Water, allowing the undissolved Tin to remain in the Solution." *Br.*

Solution of Sulphurous Acid. "The Sulphurous Acid of the British Pharmacopœia." *Br.*

Solution of Tannic Acid. "Tannic Acid, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve. Solution of Tannic Acid should be freshly prepared." *Br.*

Solution of Tartarated Antimony. "Tartarated Antimony, 10 grammes; Distilled Water, boiling, sufficient to produce 200 cubic centimetres. Dissolve and filter. Solution of Tartarated Antimony should be freshly prepared." *Br.*

Solution of Tartaric Acid. "Tartaric Acid, in crystals, 25 grammes; Alcohol (90 per cent.), 50 cubic centimetres; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve the Tartaric Acid in one hundred and thirty cubic centimetres of the Distilled Water; add the Alcohol; make up the required volume with Distilled Water." *Br.*

Solution of Uranium Nitrate. "Uranium Nitrate, 10 grammes; Distilled Water, sufficient to produce 200 cubic centimetres." *Br.*

Test-Solution of Ferric Chloride. "Dissolve 10 grammes of commercial anhydrous Ferric Chloride in sufficient Distilled Water to produce 200 cubic centimetres of solution. Filter if necessary." *Br.*

Test-Solution of Mercuric Chloride. "Mercuric Chloride, 10 grammes; Distilled Water, boiling, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

TESTS FOR SUBSTANCES MENTIONED IN THE TEXT OF THE BRITISH PHARMACOPŒIA.

Acetates. "Neutral acetates are decomposed by heat, yielding vapors which possess a characteristic acetous odor. Hydrogen acetate and ethyl acetate have characteristic odors. Acetates when warmed with sulphuric acid yield vapors of hydrogen acetate; or, when warmed with sulphuric acid and a small quantity of alcohol (90 per cent.), yield ethyl acetate. Test-solution of ferric chloride affords a deep red coloration with neutral or faintly acid acetates, and the resulting liquid on boiling yields a reddish-brown precipitate. On adding hydrochloric acid the red solution turns yellow. On adding test-solution of mercuric chloride the red color is not discharged (distinction from thiocyanates). Dry acetates heated with (a very minute proportion of) arsenious anhydride yield (the highly poisonous) cacodyl oxide, recognizable by its characteristic smell." *Br.*

Aluminium. "Solution of ammonia or solution of ammonium hydrosulphide affords a white gelatinous precipitate, soluble in hydrochloric acid, in acetic acid, and in solution of potassium hydroxide or solution of sodium hydroxide, but nearly insoluble in solution of ammonia and in solutions of ammonium salts, and quite insoluble when the solutions are boiled. Solution of ammonium oxalate causes no precipitate." *Br.*

Ammonium Salts. "Ammonium salts volatilize when strongly heated, generally without residue. When heated with solution of potassium hydroxide, or with solution of sodium hydroxide, ammonium

salts evolve ammonia, recognizable by its odor. Solution of platinic chloride affords with ammonium salts acidulated with hydrochloric acid a yellow crystalline precipitate, especially in the presence of alcohol. On ignition, this precipitate leaves a residue of platinum only. A concentrated solution of tartaric acid produces in concentrated solutions of ammonium salts a white crystalline precipitate, especially in the presence of much alcohol. Solution of potassio-mercuric iodide affords a brown precipitate, or a reddish-brown coloration, or, in excessively dilute solutions of ammonium salts, a yellowish tinge." *Br.*

Antimony. "Hydrogen sulphide yields, in slightly acid solutions, an orange-colored precipitate, soluble in solution of potassium hydroxide, in ammonium hydrosulphide, and in the strongest hydrochloric acid with evolution of hydrogen sulphide, but almost insoluble in solution of the official Ammonium Carbonate and in solution of potassium hydrogen sulphite. Hydrogen, generated by the interaction of zinc and diluted sulphuric acid, partially converts antimony compounds into hydrogen antimonide. A cold porcelain tile held in the flame of this gas acquires a dark metallic deposit, which is not appreciably dissolved by solution of chlorinated soda. The gas, when passed into solution of silver nitrate, causes a black precipitate containing antimony and silver, and on the cautious addition of solution of ammonia the supernatant liquid yields no yellow precipitate. If one end of a strip or rod of zinc be allowed to rest on a platinum capsule containing the acidulated antimony solution, the other end being in the liquid, hydrogen antimonide is not evolved, but the antimony is precipitated on the platinum as a black, adherent, non-granular stain, insoluble in hydrochloric acid. Copper foil precipitates antimony from solutions, and the antimony may be volatilized by heat, condensing as a white amorphous sublimate of oxides of antimony near to the copper." *Br.*

Arsenium. "Hydrogen sulphide affords in solutions containing hydrochloric acid a yellow precipitate, soluble in solution of potassium hydroxide, potassium carbonate, ammonium hydrosulphide, and potassium hydrogen sulphite, and in solution of the official Ammonium Carbonate, but reprecipitated on addition of hydrochloric acid. The precipitate is insoluble in the strongest hydrochloric acid.

"Nascent hydrogen, generated by the interaction of zinc and diluted sulphuric acid, converts arsenium compounds into hydrogen arsenide. A cold porcelain tile held in the flame of this gas acquires a dark metallic deposit, which is readily dissolved by solution of chlorinated soda. The gas, when passed into excess of solution of silver nitrate, causes a black precipitate of silver, and the cautious addition of solution of ammonia to the supernatant liquid causes a yellow precipitate. Hydrogen, generated by the interaction of zinc and solution of potassium hydroxide or sodium hydroxide, converts arsenium compounds into hydrogen arsenide. This gas gives a black stain to filtering paper soaked with solution of silver nitrate and placed as a cap over the tube in which the test is being performed. Hydrogen antimonide is not evolved from antimony compounds under similar circumstances. The operation should be performed in an atmosphere which is free from hydrogen sulphide. Stannous chloride dissolved in a large excess of hydrochloric acid gives on boiling with a solution containing arsenium a brownish-black precipitate. Bright copper foil precipitates arsenium from solutions acidulated by hydrochloric acid, and the arsenium may be volatilized by heat in an open tube, when it condenses, at some distance from the copper, as a white sublimate of characteristic octahedral crystals. *Arsenites.*—Solutions of arsenites yield a yellow precipitate with solution of silver ammonio-nitrate. *Arsenates.*—Solutions of arsenates yield a reddish-chocolate precipitate with solution of silver ammonio-nitrate. Solution of magnesium ammonio-sulphate affords a white crystalline precipitate." *Br.*

Bismuth. "Hydrogen sulphide affords a brownish-black precipitate, insoluble in solution of potassium hydroxide, of potassium cyanide, in diluted hydrochloric acid, and in ammonium hydrosulphide, but decomposed and dissolved by boiling nitric acid. Solution of potassium hydroxide, sodium hydroxide, or ammonia, except in the presence of citrates, yields a white precipitate insoluble in excess of the precipitant. Dilute solution of sodium chloride in large excess gives in solutions which are not too acid a white precipitate, insoluble in tartaric acid. Solution of potassium chromate gives a yellow precipitate, soluble in dilute nitric acid, insoluble in solution of potassium hydroxide. Stannous chloride dissolved in a concentrated solution of potassium hydroxide gives a black precipitate when added in excess to a solution containing bismuth. Diluted sulphuric acid does not precipitate bismuth salts." *Br.*

Bromates. "From bromates solution of sulphurous acid liberates bromine, recognizable by its odor and appearance. After ignition with charcoal bromates are converted into bromides, and the latter yield their characteristic reactions." *Br.*

Bromides or Hydrobromides. "Solution of silver nitrate gives a yellowish curdy precipitate, readily soluble in solution of potassium cyanide, somewhat soluble in strong but almost insoluble in weak solution of ammonia, and insoluble in nitric acid. Solution of sodium nitrite with the addition of diluted hydrochloric acid does not liberate bromine from a bromide. Solution of chlorine liberates bromine soluble in two or three drops of carbon bisulphide or of chloroform, and forming a reddish solution. Bromine is liberated when a bromide is heated with sulphuric acid and manganese peroxide, lead peroxide, or potassium bichromate, the vapor giving an orange-yellow color to filter-paper soaked in mucilage of starch. In testing for bromides in the presence of iodides, all iodine should be first removed by boiling the aqueous solution with excess of lead peroxide." *Br.*

Cadmium. "Hydrogen sulphide yields a yellow precipitate, insoluble in cold dilute hydrochloric acid, in solutions of ammonium hydrosulphide, of potassium hydroxide, and of potassium cyanide, but soluble in nitric acid, in hot diluted hydrochloric acid, and in hot diluted sulphuric acid. Solution of potassium hydroxide and solution of sodium hydroxide afford white precipitates insoluble in excess. Solution of ammonia gives a white precipitate readily soluble in excess." *Br.*

Calcium. "Solution of ammonium carbonate yields a white precipitate, which, after boiling well and setting aside the mixture, is insoluble in solution of ammonium chloride. Solution of ammonium oxalate gives a white precipitate, soluble in hydrochloric acid, but insoluble in acetic acid. Solution of potassium chromate gives no precipitate." *Br.*

Carbonates and Bicarbonates. "Dilute acids cause an effervescence of carbonic anhydride, which is odorless, and causes a white precipitate in solution of lime, or in solution of barium hydroxide. Soluble carbonates afford a brownish-red precipitate with test-solution of mercuric chloride, bicarbonates a whitish precipitate; the former yield a white precipitate with a cold solution of magnesium sulphate, the latter do not." *Br.*

Chlorides or Hydrochlorides. "Solution of silver nitrate affords a white curdy precipitate, soluble in solution of ammonia or solution of potassium cyanide, but insoluble in nitric acid. A solid chloride or hydrochloride, when subjected to distillation with sulphuric acid and potassium bichromate, yields a reddish-brown distillate, which is decomposed by water. The resulting solution when nearly neutralized gives a yellow precipitate with solution of lead acetate or solution of barium chloride, and a mixed red and white precipitate with solution of silver nitrate, of which the red portion is dissolved by nitric acid, and both portions by solution of ammonia. Heated with manganese peroxide and sulphuric acid, chlorides or hydrochlorides yield chlorine, recognizable by its odor and by giving a blue color with solution of potassium iodide and mucilage of starch." *Br.*

Citrates. "Citrates become charred when heated. Solution of calcium chloride added in excess affords, when boiled with a neutral solution of a citrate, a white precipitate, insoluble in solution of potassium hydroxide, but soluble in solution of ammonium chloride and in solutions of alkaline citrates. Solution of silver nitrate causes in solutions of neutral citrates a white precipitate soluble in solution of ammonia. A mirror is not formed on the sides of the tube when the ammoniacal solution is warmed (distinction from tartrates)." *Br.*

Copper. "Hydrogen sulphide or solution of ammonium hydrosulphide yields in solutions which are not strongly acid a brownish-black precipitate, insoluble in dilute hydrochloric acid and in solution of potassium hydroxide, almost insoluble in solution of ammonium hydrosulphide, but decomposed and dissolved by boiling nitric acid, and when freshly precipitated soluble in solution of potassium cyanide. Solution of potassium hydroxide gives a bulky light blue precipitate which becomes brownish black on boiling. The light blue precipitate is soluble in a very large excess of a concentrated solution of potassium hydroxide, forming a blue solution. In the presence of soluble tartrates or citrates the light blue precipitate dissolves at once in the solution of potassium hydroxide, yielding a blue liquid which is not affected on boiling. Dextrose and other sugars act similarly, but the resulting solution, on warming, affords a yellowish-red to bright red precipitate. In the presence of non-volatile organic acids solution of potassium hydroxide produces no precipitate, but on the addition of the reagent the solution becomes deep blue. Solution of ammonia or of ammonium carbonate added in small quantity to a neutral solution of a copper salt gives a greenish-blue precipitate which readily dissolves in excess of solution of ammonia, forming a deep blue solution. This blue coloration is perceptible in highly dilute solutions. Solution of potassium ferrocyanide gives a reddish-brown precipitate, or in very dilute solutions a reddish-brown coloration, unaffected by dilute acids but decomposed by solution of potassium hydroxide. Metallic iron receives a reddish coating of copper when placed in a solution of a copper salt." *Br.*

Cyanides. "Solution of silver nitrate affords a white curdy precipitate, soluble in solution of potassium cyanide, in solution of ammonia, and in boiling concentrated nitric acid. If to a soluble cyanide be added a few drops of a mixed solution of ferrous and ferric salts, then of solution of sodium hydroxide, and lastly excess of hydrochloric acid, a precipitate of Prussian blue results. Insoluble cyanides decompose when heated, evolving cyanogen, which burns with a characteristic peach-colored flame." *Br.*

Hydrobromides. See "Bromides," page 1863.

Hydrochlorides. See "Chlorides," above.

Iodates. "Solution of silver nitrate gives a white crystalline precipitate, sparingly soluble in water and in dilute nitric acid, but readily dissolved by solution of ammonia. Solution of sulphurous acid when added to the ammoniacal solution gives a pale yellow precipitate. A mixed solution of potassium iodide and tartaric acid in a solution of an iodate yields iodine, which affords a blue color with mucilage of starch. Solution of barium chloride gives a white precipitate nearly insoluble in water and soluble with difficulty in diluted nitric acid. On the addition of mucilage of starch and solution of sulphurous acid a blue color is produced." *Br.*

Iodides. "Solution of silver nitrate affords a curdy yellow precipitate, insoluble in nitric acid and almost insoluble in solution of ammonia, but soluble in solution of potassium cyanide. Solution of mercurous nitrate produces a green precipitate, insoluble in diluted nitric acid, soluble in solution of potassium iodide. Test-solution of mercuric chloride yields a scarlet precipitate, slightly soluble in excess of this reagent, and very soluble in solution of potassium iodide. Solution of lead acetate causes a yellow precipitate, soluble in diluted nitric acid and soluble in boiling water. From the latter solution the precipitate separates in golden crystalline scales as the solution cools. Solution of copper sulphate, mixed with the solution of ferrous sulphate or of sulphurous acid, affords a whitish precipitate, soluble in solution of ammonia, sparingly soluble in hydrochloric acid. A small quantity of solution of chlorine or bromine, or a solution of sodium nitrite and diluted hydrochloric acid, liberates iodine. A very minute quantity of free iodine produces an intense blue coloration with mucilage of starch. If liquid containing free iodine be shaken with carbon bisulphide, the iodine is dissolved by the carbon bisulphide and communicates a violet color to it." *Br.*

Iron. "Reactions common to Ferrous and Ferric salts: Solution of ammonium hydrosulphide yields, in neutral solutions, a black precipitate soluble in cold diluted hydrochloric acid with evolution of hydrogen sulphide. Solution of potassium ferrocyanide gives a blue precipitate, or a white precipitate rapidly turning blue, insoluble in dilute hydrochloric acid, decomposed by solution of potassium hydroxide or by solution of sodium hydroxide.

"Reactions characteristic of Ferrous salts: Hydrogen sulphide causes no precipitate in a slightly acid solution. Solution of potassium ferricyanide affords a dark blue precipitate, insoluble in dilute hydrochloric acid, decomposed by solution of potassium hydroxide or solution of sodium hydroxide. (Ferric salts give a reddish-brown coloration but no precipitate with this reagent.) Ferrous salts mixed with solution of potassium or sodium hydroxide give a dull green precipitate.

"Reactions characteristic of Ferric salts: Hydrogen sulphide gives a white precipitate of sulphur. Solution of ammonium thiocyanate produces a blood-red coloration, which is discharged on the addition of test-solution of mercuric chloride. Solution of tannic acid yields a bluish-black coloration or precipitate with ferric salts, and, more slowly, with ferrous salts. Solution of potassium, sodium, or ammonium hydroxide causes a reddish-brown precipitate, soluble in solution of citric or tartaric acid, and not formed in the presence of citrates and tartrates." *Br.*

Lead. "Hydrochloric acid affords, except in very weak solutions, a white precipitate soluble in boiling water. The aqueous solution as it cools deposits the lead chloride in the crystalline form. Hydrogen sulphide in not very strongly acid solutions yields a black precipitate insoluble in dilute hydrochloric acid, solution of potassium hydroxide, and solution of ammonium hydrosulphide. It is decomposed by boiling with diluted nitric acid, being partly converted into soluble lead nitrate and partly into white insoluble lead sulphate and sulphur. Diluted sulphuric acid causes a white precipitate almost insoluble in water, and still less soluble in dilute sulphuric acid and in alcohol, but soluble in solution of ammonium acetate. Solution of potassium chromate produces a yellow precipitate readily soluble in solution of potassium hydroxide, in strong, hot nitric acid, sparingly soluble in diluted nitric acid, insoluble in acetic acid. Solution of potassium hydroxide gives a white precipitate soluble in excess of the reagent, but insoluble in solution of ammonia." *Br.*

Magnesium. "Solution of ammonium carbonate, in the presence of solution of ammonium chloride, affords no precipitate. Solution of sodium phosphate, or solution of sodium arsenate, in the presence of ammonium salts and solution of ammonia, yields a white crystalline precipitate. Solution of potassium, sodium, ammonium, barium, or calcium hydroxide causes a white precipitate, insoluble in excess of the reagent, but soluble in solution of ammonium chloride." *Br.*

Mercury. "Reactions common to Mercurous and Mercuric salts: Hydrogen sulphide yields a black precipitate, insoluble in solution of ammonium hydrosulphide and in boiling diluted nitric acid. Copper foil immersed in a solution free from excess of nitric acid becomes coated with a deposit of mercury which on rubbing becomes bright, and from which the mercury may be volatilized by heat and obtained in globules. Solution of stannous chloride reduces mercuric salts, first to mercurous salts and then to metallic mercury.

"Reactions characteristic of Mercurous salts: Hydrochloric acid affords a white precipitate insoluble in water, which is blackened by solution of ammonia. Solution of potassium or sodium hydroxide produces a black precipitate of mercurous oxide, and solution of ammonia a black precipitate of a mercurous-amido salt. Solution of potassium iodide gives a green precipitate soluble in excess of the precipitant.

"Reactions characteristic of Mercuric salts: Solution of ammonia affords a white precipitate. Solutions of potassium or sodium hydroxide yield a yellow precipitate of mercuric oxide. Solution of potassium iodide produces a scarlet precipitate, soluble in excess of the precipitant, and in a considerable excess of the solution of the mercuric salt." *Br.*

Nitrates. "Ferrous sulphate and sulphuric acid, when added to a solution of a nitrate in such a way that the acid forms a stratum below the aqueous solution, cause a purple or brown coloration at the junction of the two liquids. Nitrates liberate red fumes when warmed with sulphuric acid and copper. Nitrates discharge the color of solution of indigo sulphate containing excess of sulphuric acid, especially if the mixture is warmed." *Br.*

Nitrites. "On the addition, to a solution of a nitrite, of a few drops of diluted sulphuric acid, solution of potassum iodide, and mucilage of starch, a blue color is produced. Diluted sulphuric acid affords red fumes. Solution of ferrous sulphate and acetic acid yield a deep brown color." *Br.*

Oxalates. "Solution of calcium chloride affords a white precipitate, soluble in hydrochloric acid, but insoluble in acetic acid. Solution of silver nitrate yields a white precipitate, soluble in solution of ammonia and in diluted nitric acid. Most oxalates are on ignition converted into carbonates. Oxalates do not char when heated with sulphuric acid, but yield carbonic oxide and carbonic anhydride." *Br.*

Phosphates (Ortho-). "Solution of silver ammonio-nitrate yields in solution of ortho-phosphates a light yellow precipitate readily soluble in solution of ammonia and in cold dilute nitric acid. Test-solution of ferric chloride, in the presence of ammonium acetate or other acetate, yields a whitish precipitate, insoluble in acetic acid. Solution of magnesium ammonio-sulphate affords a white crystalline precipitate. Excess of solution of ammonium molybdate, containing much nitric acid, produces, on warming, a yellow precipitate." *Br.*

Potassium. "Solution of platinic chloride affords with moderately strong solutions of potassium chloride (or with other potassium salts if hydrochloric acid be present) a yellow crystalline precipitate, which, upon ignition, leaves a residue of potassium chloride and platinum. Potassium compounds moistened with hydrochloric acid communicate a violet coloration when introduced, on platinum wire, into the flame of a spirit lamp or Bunsen burner." *Br.*

Selenium and Tellurium. "Selenium and Tellurium may occur in compounds of bismuth. To detect these elements, dissolve the compound in nitric acid, add solution of sodium chloride or ammonium chloride, and dilute freely with water. The filtrate from the precipitated oxychloride, mixed with excess of sodium sulphite, should give no precipitate or coloration even after twelve hours." *Br.*

Silica. "Silica, after exposure to a red heat, is insoluble in acids, and is not dissolved in a bead of microcosmic salt when heated to fusion in the blow-pipe flame. The result of its fusion with alkalies is soluble in water, the solution yielding a gelatinous precipitate on the addition of hydrochloric acid." *Br.*

Silver. "Hydrochloric acid and other chlorides afford a white curdy precipitate, soluble in solution of ammonia, but insoluble in nitric acid. Solution of potassium chromate, in the absence of chlorides, bromides, and iodides, affords a red precipitate." *Br.*

Sodium. "Sodium compounds, moistened with hydrochloric acid, communicate a yellow coloration when introduced, on platinum wire, into the flame of a spirit lamp or Bunsen burner." *Br.*

Starch. "When starch is boiled with water, the mixture, on cooling, affords a deep blue coloration on the addition of solution of iodine. When boiled for some minutes with water acidulated with hydrochloric acid, and then made alkaline with sodium hydroxide, a red precipitate is formed on further boiling after the addition of solution of potassio-cupric tartrate. The varieties of starch may be distinguished by their microscopical characters." *Br.*

Sulphates. "Solution of barium chloride affords a white precipitate insoluble in hydrochloric acid." *Br.*

Sulphides. "The official sulphides, hydrosulphides, and sulphurated compounds evolve hydrogen sulphide when boiled with strong hydrochloric acid. Sulphonal and thiocyanates do not evolve hydrogen sulphide when treated in this way. If fused with sodium carbonate, mixed with a small proportion of potassium nitrate, they afford a mass which, when dissolved in water, responds to the tests for sulphates." *Br.*

Sulphites. "Hydrochloric acid liberates sulphurous anhydride, a colorless gas with a pungent smell of burning sulphur. Hydrochloric acid and zinc being added, hydrogen sulphide, recognizable by its odor, is liberated. Sulphites decolorize solution of iodine." *Br.*

Tartrates. "Tartrates become charred when heated. Solution of calcium chloride added in excess to a solution of a neutral tartrate affords a white granular precipitate, soluble, when fresh, in cold moderately concentrated solution of potassium hydroxide, from which it is precipitated on boiling. It is also soluble in tartaric acid. Solution of silver nitrate yields a white precipitate, soluble in solution of ammonia and in nitric acid. The ammoniacal solution is reduced on heating, and deposits metallic silver as a mirror on the sides of the test-tube. A concentrated solution of potassium acetate gives a white precipitate in moderately concentrated solutions when acidulated with acetic acid and well stirred, and especially on the addition of alcohol (90 per cent.). If to the solution of tartaric acid in water, or of a tartrate acidulated with acetic acid, be added a drop of solution of ferrous sulphate, then a few drops of solution of hydrogen peroxide, and finally an excess of solution of potassium hydroxide, a purple or violet color will be produced." *Br.*

Tellurium. See "Selenium," above.

Thiosulphates. "Hydrochloric acid gives a yellow precipitate and liberates sulphurous anhydride, recognizable by its odor. Hydrochloric acid and zinc liberate hydrogen sulphide. Thiosulphates decolorize solution of iodine." *Br.*

Tin. "Metallic zinc placed in a solution of any tin salt acidulated with hydrochloric acid precipitates the whole of the tin in metallic scales or as a gray sponge. The metal, separated from the liquid, is soluble in boiling concentrated hydrochloric acid, and the solution, which contains stannous chloride, gives with test-solution of mercuric chloride a white precipitate of calomel, which becomes gray from separation of metallic mercury, if excess of tin salt is present." *Br.*

Zinc. "Solution of ammonium hydrosulphide yields with neutral, and hydrogen sulphide with alkaline, solutions a white precipitate, soluble in hydrochloric acid, but insoluble in acetic acid. Solution of potassium hydroxide or of ammonia affords a white precipitate, soluble in excess of either reagent. Solution of potassium ferrocyanide produces a white precipitate, insoluble in diluted hydrochloric acid." *Br.*

TEST-SOLUTIONS FOR VOLUMETRIC ESTIMATIONS.

"The following apparatus is required in the preparation and use of these solutions. 1. A glass flask which, when filled to a mark on the neck, contains 1000 grammes of distilled water at 60° F. (15·5° C.). This flask is described as the 'one-litre flask,' and is used in ordinary analytical operations to measure 1000 cubic centimetres, as it is customary for the sake of convenience to make the measurement of liquids with metric apparatus which has thus been graduated at 60° F. (15·5° C.). 2. A graduated cylindrical jar which, when filled to the zero mark at 60° F. (15·5° C.), contains 1000 grammes of distilled water, and is divided into 100 equal parts, each of which is taken as corresponding to 10 cubic centimetres. 3. A burette. A graduated tube which, when filled to the zero mark at 60° F. (15·5° C.), holds, within the graduated portion, 50 grammes of distilled water; the graduated portion is divided into 50 equal parts, each of which is taken as corresponding to 1 cubic centimetre, and each such division is subdivided into 10 equal parts. A standard Litre contains 1 kilogramme (1000 grammes) of distilled water at the temperature of maximum density (39·2° F. or 4° C.), and at the barometric pressure

of 760 millimetres of mercury. One-thousandth part of a standard Litre (one millilitre) is, strictly speaking, equivalent to 1·00016 cubic centimetres, or one cubic centimetre to 0·99984 millilitre. Any litre-measure or other piece of volumetric apparatus not actually marked '60° F.' or '15·5° C.' is to be taken as having reference to the standard Litre graduated at 39·2° F. or 4° C. Volumetric solutions, before being used, should be shaken, in order that they may be throughout of uniform strength. They should also be preserved in stoppered bottles." *Br.*

Volumetric Solution of Iodine. (Iodine, 1 = 125·9.) "Iodine, 12·59 grammes; Potassium Iodide, 18 grammes; Distilled Water, a sufficient quantity. The Iodine should be pure. It may be obtained pure by mixing the official 'Iodum' with one-fourth of its weight of dry potassium iodide, resubliming, and leaving the resulting crystals for a few hours under a glass shade placed over a dish containing concentrated sulphuric acid. Put the Iodine and the Potassium Iodide (which should be pure), with about 20 cubic centimetres of Distilled Water, into the one-litre flask; gently agitate until solution is complete; then dilute the solution with Distilled Water until it measures 1000 cubic centimetres. The strength of this Solution should be verified by the aid of pure arsenious anhydride, pure barium thiosulphate, or other suitable substance, and the Solution (a) be either strengthened or diluted, so that 1000 cubic centimetres shall contain exactly 12 59 grammes of iodine; or (b) have its actual strength noted, so that calculations may be made accordingly when the Solution is used." *Br.*

Volumetric Solution of Potassium Bichromate. (Potassium Bichromate, $K_2Cr_2O_7 = 292·3$.) "Potassium Bichromate, 4·87 grammes; Distilled Water, a sufficient quantity. Put the Potassium Bichromate into the one-litre flask; dissolve it in about half a litre of Distilled Water; dilute the solution with Distilled Water until it has the exact bulk of 1000 cubic centimetres. 100 cubic centimetres of this solution yield 0·0794 gramme of oxygen, and are therefore capable of converting 0·556 gramme of iron from the ferrous to the ferric state. The strength of this Solution should be verified by the aid of pure ferrous ammonium sulphate, or other trustworthy substance, and the Solution (a) be either strengthened or diluted, so that 1000 cubic centimetres shall contain exactly 4·87 grammes of potassium bichromate; or (b) have its actual strength noted, so that calculations may be made accordingly when the Solution is used." *Br.*

Volumetric Solution of Silver Nitrate. (Silver Nitrate, $AgNO_3 = 168·69$.) "Silver Nitrate, 16·869 grammes; Distilled Water, a sufficient quantity. Put the Silver Nitrate into the one-litre flask; dissolve it in about half a litre of Distilled Water; dilute the solution with Distilled Water until it has the exact bulk of 1000 cubic centimetres. The Solution should be kept in an opaque stoppered bottle. The strength of this Solution should be verified by the aid of pure sodium chloride or solution of pure hydrochloric acid of known strength, and the Solution (a) be either strengthened or diluted, so that 1000 cubic centimetres shall contain exactly 16·869 grammes of silver nitrate; or (b) have its actual strength noted, so that calculations may be made accordingly when the Solution is used." *Br.*

Volumetric Solution of Sodium Hydroxide. (Sodium Hydroxide, NaOH = 39·76.) "Purified Sodium Hydroxide, 42 grammes; Distilled Water, a sufficient quantity. Dissolve the Purified Sodium Hydroxide in 1000 cubic centimetres of Distilled Water. Fill a burette with the solution of sodium hydroxide, and cautiously drop this into 100 cubic centimetres of the volumetric solution of sulphuric acid until the acid is exactly neutralized as indicated by litmus. Note the number of cubic centimetres (n) of the solution of sodium hydroxide used, and having then introduced 800 cubic centimetres of it into a graduated jar, augment this quantity by the addition of water, until it becomes $800 \times 100 \div n$ cubic centimetres. 1000 cubic centimetres then contain exactly 39·76 grammes of sodium hydroxide. A decinormal volumetric solution of sodium hydroxide may be prepared by adding, to 100 cubic centimetres of the above volumetric solution, sufficient Distilled Water to produce 1000 cubic centimetres. Alcoholic solutions, normal and decinormal.—Alcohol (90 per cent.) may, when necessary, be used as the solvent. An equivalent proportion of potassium hydroxide, KOH = 55·71, may in certain cases be employed in the place of sodium hydroxide." *Br.*

Volumetric Solution of Sodium Thiosulphate. (Sodium Thiosulphate, crystallized, $Na_2S_2O_3,5H_2O = 246·44$.) "Sodium Thiosulphate, in crystals, 28 grammes; Distilled Water, a sufficient quantity. Dissolve the Sodium Thiosulphate in 1000 cubic centimetres of Distilled Water. Fill a burette with this solution, and drop it cautiously into 100 cubic centimetres of the volumetric solution of iodine, until only a faint brown or yellow color remains. Add mucilage of starch and continue the addition of the thiosulphate solution until the blue color is discharged. Note the number of cubic centimetres (n) required to produce this effect; then put 800 cubic centimetres of the same solution into a graduated jar, and augment this quantity by the addition of Distilled Water until it amounts to $800 \times 100 \div n$ cubic centimetres. 1000 cubic centimetres then contain exactly 24·644 grammes of sodium thiosulphate." *Br.*

Volumetric Solution of Sulphuric Acid. (Sulphuric Acid, $H_2SO_4 = 97·34$.) "Sulphuric Acid, 50 grammes; Distilled Water, a sufficient quantity. Dilute the Sulphuric Acid with 900 cubic centimetres of Distilled Water; cool. Prepare a small quantity of sodium carbonate by heating pure sodium bicarbonate to redness in a platinum crucible for a quarter of an hour. Make a solution of 1·053 grammes of the sodium carbonate, and add to it from a burette the solution of sulphuric acid until exact neutrality is obtained, taking care to boil off the carbonic anhydride. Note the number of cubic centimetres used (n); then put 900 cubic centimetres of the solution of sulphuric acid into a graduated jar, and augment this quantity by the addition of Distilled Water until it amounts to $900 \times 20 \div n$ cubic centimetres. 1000 cubic centimetres then contain exactly 48·67 grammes of sulphuric acid. A decinormal volumetric solution of sulphuric acid may be prepared by adding, to 100 cubic centimetres of the above volumetric solution, sufficient Distilled Water to produce 1000 cubic centimetres." *Br.*

INDICATORS OF THE TERMINATION OF REACTIONS IN VOLUMETRIC ESTIMATIONS.

Mucilage of Starch. "It gives an intensely blue color with iodine, at ordinary temperatures." *Br.*

Solution of Litmus. "It gives a red color with acids and a blue color with alkalies. It is not distinctly reddened by boric acid. It is reddened by moist carbonic anhydride; hence, when estimating a carbonate with a volumetric solution of an acid, the termination of the reaction is indicated by the neutral tint of the litmus after the liquid under examination has been well boiled." *Br.*

Solution of Methyl Orange. "It gives a pink color with mineral acids and a faint yellow color with alkalies. It is a trustworthy indicator of excess of ammonia. It is not reddened by moist carbonic anhydride or boric acid." *Br.*

Solution of Neutral Potassium Chromate. "It gives a red precipitate with silver nitrate, but not while any soluble chloride, bromide, or iodide is present." *Br.*

Solution of Phenol-Phthalein. "It gives a red color with alkalies, which is discharged by acids. It is the most trustworthy indicator of excess of organic acids. It does not accurately indicate the point of neutralization of ammonia with an acid. For the latter, Tincture of Cochineal is an appropriate indicator." *Br.*

Solution of Potassium Ferricyanide. "It gives an intensely blue precipitate or coloration with ferrous salts, but none with ferric salts." *Br.*

ART OF PRESCRIBING MEDICINES.

The art of prescribing medicines, *i.e.*, of adapting them to the treatment of individual cases, is one of prime importance, which, however, can scarcely with propriety be fully discussed in a work like the present. As explanatory of our own text, and as affording some guidance to the young practitioner, and also to the apothecary in interpreting prescriptions, we offer a few remarks, with practical examples.

1. Dose of Medicines. In this work a minimum and a maximum dose for adults are usually given for each article. In interpreting these doses the practitioner should remember that it is rarely proper to begin with the amount stated as maximum, whilst, on the other hand, the minimum dose will only in exceptional cases produce the full physiological effect of the remedy. When a powerful remedy is being used, and a decided effect is desired, it is best to commence with the smaller dose and to increase cautiously. There are various circumstances modifying the dose which demand attention.

Age. The young require a smaller dose than those of maturity; and the old, though their systems are, perhaps, less susceptible to the action of medicines than those of the middle-aged, cannot bear an equally forcible impression from depressing remedies.

The following rule of Dr. Young is almost universally adopted.

"For children under twelve years, the doses of most medicines must be diminished in the proportion of the age to the age increased by twelve; thus, at two years to $\frac{1}{7}$; viz., $\frac{2}{2+12}=\frac{1}{7}$. At twenty-one the full dose may be given."

To the above rule some exceptions are offered in particular medicines. Thus, purgatives, diaphoretics, and diuretics must usually be given to children in larger, and narcotics in smaller, doses than those called for by Young's rule. A babe six months old will often not be affected by one-fourth the adult dose of castor oil, or one-sixth the dose of calomel, but will not bear well more than one twenty-fifth the dose of opium.

Sex, Temperament, and Idiosyncrasy. Females usually require somewhat smaller doses than males, and persons of sanguine temperament than the phlegmatic. Constitutional peculiarities, called idiosyncrasies, often exist in individuals, rendering them more than usually susceptible or insusceptible to the action of certain remedies, the dose of which must be modified accordingly. Thus, in some persons a grain or two of calomel will excite salivation, while in others scarcely any quantity which can be safely administered will produce this effect. Sometimes, moreover, a medicine operates on an individual in a manner wholly different from its ordinary mode. In all such cases experience is the only sure guide; and when a physician is called to a patient, not before known, careful inquiries should always be made.

Habit. Generally speaking, the susceptibility to the action of medicines is diminished by their frequent and continued use; and, in order to maintain a given impression, the quantity must be regularly increased. This is especially true in regard to the narcotics, which are sometimes borne in enormous doses by those habituated to their use. It is a good practical rule in prescribing, when circumstances demand the continuance, for a considerable length of time, of some particular effect, to vary the medicine, and employ successively several with the same general powers, so as not too rapidly to exhaust the susceptibility to the action of any individual remedy. A patient accustomed to one narcotic is usually found blunted towards other cognate medicines.

2. Mode of administering Medicines. This has reference both to the combination of medicines with one another, and to the form in which they are exhibited.

Simplicity in prescription is always desirable. Remedies should never be mixed together without a definite purpose. Those exceedingly complex prescriptions, formerly so much in vogue, of which the ingredients were so numerous as to render altogether impossible a reasonable estimate of their bearing on

each other, or of their effects on disease, have been generally abandoned by modern practitioners. The only ground upon which any of them can be justifiably retained is that, by very frequent trials, through a long course of years, and in various states of disease, their influence on the system may have been fully ascertained, so that they may be considered rather in the light of a single remedy than a compound of many. A brief enunciation of a few general principles in regard to the art of combination may be useful.

Remedies of the same general character may be given in connection, in order to increase their energy, or to render their action more certain. It has been well ascertained that substances thus combined will often act vigorously, when, severally, they would produce comparatively little effect; and it sometimes happens that, while their activity is augmented, they are rendered less irritating, as in the case of the drastic cathartics.

Different medicines are very often mixed together, in order to meet different and coexisting indications, without any reference to the influence which they may reciprocally exert on each other. Thus, in the same patient we not unfrequently meet with debility of stomach and constipation of the bowels, connected with derangement of the hepatic function. To answer the indications presented by these morbid conditions, we may properly combine, in the same dose, a tonic, cathartic, and mercurial alterative. For similar reasons we often unite tonics, purgatives, and emmenagogues, anodynes and diaphoretics, emetics and cathartics, antacids, astringents, and tonics.

Medicines acting differently in certain respects are combined to modify each other's powers, or to gain strength at some especial point where their actions overlap. In this way seemingly new powers are sometimes developed, and those previously existing are greatly increased. Examples of such a result are afforded in the official powder of ipecacuanha and opium, which acts as a diaphoretic beyond the capabilities of either of its constituents. The effects of one medicine are, in numerous instances, increased by the influence of another in augmenting the natural susceptibility of the system to its action. Thus, bitters enable cathartics to operate in smaller doses; purgatives awaken the dormant susceptibility to the action of mercury. In some instances, the action of one medicine is promoted by that of another apparently of a nature wholly opposite. Thus, when calomel and opium are given in colic, the purgative operation of the former is facilitated by the relaxation of intestinal spasm produced by the latter. Medicines, in addition to the effects for which they are administered, very frequently produce disagreeable symptoms, which may be moderated or altogether prevented by combination with other medicines, and this object may usually be accomplished without in the least degree interfering with the remedial influence desired. Thus, the griping produced by cathartics, and the nausea by these and various other medicines, may be often corrected by the simultaneous use of aromatics. To cover the disagreeable taste or odor of certain medicines, and to afford a convenient vehicle for their administration, are also important objects of combination; as upon these circumstances often depend the acceptability of the medicine to the stomach, and even the possibility of inducing the patient to swallow it. Substances should be preferred as vehicles which are calculated to render the medicine acceptable to the palate and stomach, and in other ways to correct its disagreeable effects; as syrups for powders, the aromatic waters for medicines given in the form of mixture, and carbonic-acid water for the neutral salts.

But, in the mixing of medicines, care should be taken that they are neither chemically nor physiologically incompatible; in other words, that they are not such as will react on each other so as to produce new and unexpected combinations, nor such as will exert contrary and opposite effects upon the system. Thus, when the operation of an acid is desired, an alkali should not be given at the same time, as they unite to form a third substance entirely different from either; nor should a soluble salt of lime, barium, or lead be given with sulphuric acid or a soluble sulphate, as decomposition would ensue, with the production of an inert compound. So, also, in relation to physiological incompatibility, diaphoretics and diuretics should not, as a general rule, be united with a view to their respective effects; as these are to a certain extent incompatible, one being diminished by whatever has a tendency to increase the other. There are cases, however, in which we may advantageously combine medicines with a view to their chemical reaction, as in the instance of the effervescing draught; and circumstances sometimes call for the union of remedies apparently opposite, as in the case of colic before alluded to, in which opium may be advantageously combined with purgatives. Still, such combinations should never be formed unless with a full understanding of their effects.

The *form in which medicines are exhibited* is often an object of considerable importance. By variation in this respect, according to the nature of the medicine, the taste of the patient, or the condition of the stomach, we are frequently enabled to secure the favorable operation of remedies, which, without such attention, might prove useless or injurious. Medicines may be given in the solid state, as in the form of powder, pill, troche, or electuary; in the state of mixture, in which a solid is suspended in a liquid, or one liquid is mechanically mixed with another in which it is insoluble; or in the state of solution, under which may be included the various forms of infusion, decoction, tincture, fluid extract, wine, vinegar, syrup, honey, and oxymel.

In writing extemporaneous prescriptions, neatness, order, and precision should always be observed; as, independently of the pleasing moral effect, a positive practical advantage results in the greater accuracy which the habit of attending to them gives to the prescriber, and the comparative certainty which they afford that his directions will be strictly complied with. As a general rule, when medicines are combined in prescription, the most important should come first in order, next the adjuvant or corrigent, and lastly the vehicle. Sometimes, however, it is important to indicate to the pharmacist the succession in which the substances should be combined, and this may render convenient a deviation from the order above mentioned. The physician should always be careful either to write out the full name of the medicine, or to employ such abbreviations as cannot be misunderstood. Fatal mistakes have been occasioned by a neglect of this precaution. The following table and formulas explain and illustrate the signs, abbreviations, and methods habitually used in prescribing.

Table of Signs and Abbreviations.

℞	Recipe.	Take.	Collyr.	Collyrium.	An eye-water.
āā	Ana.	Of each.	Cong.	Congius vel congii.	A gallon or gallons.
℔	Libra vel libræ.	A pound or pounds.	Decoct.	Decoctum.	A decoction.
℥	Uncia vel unciæ.	An ounce or ounces.	Ft.	Fiat.	Make.
ʒ	Drachma vel drachmæ.	A drachm or drachms.	Garg.	Gargarysma.	A gargle.
℈	Scrupulus vel scrupuli.	A scruple or scruples.	Gm.	Gramme or gram.	15·5 grains.
			Gr.	Granum vel grana.	A grain or grains.
			Gtt.	Gutta vel guttæ.	A drop or drops.
O	Octarius vel octarii.	A pint or pints.	Haust.	Haustus.	A draught.
f℥	Fluiduncia vel fluiduncie.	A fluidounce or fluidounces.	Infus.	Infusum.	An infusion.
			M.	Misce.	Mix.
fʒ	Fluidrachma vel fluidrachmæ.	A fluidrachm or fluidrachms.	Mass.	Massa.	A mass.
			Mist.	Mistura.	A mixture.
♏	Minimum vel minima.	A minim or minims.	Pil.	Pilula vel pilulæ.	A pill or pills.
			Pulv.	Pulvis vel pulveres.	A powder or powders.
C.c.	Cubic centimeter.	About 16 minims.			
Chart.	Chartula vel chartulæ.	A small paper or papers.	Q. S.	Quantum sufficit.	A sufficient quantity.
Coch.	Cochlear vel cochlearia.	A spoonful or spoonfuls.	S.	Signa.	Write.
			Ss.	Semis.	A half.

Examples of Common Extemporaneous Prescriptions.

Powders.

℞ Zinci Sulphatis,
Pulveris Ipecacuanhæ, āā, gr. xx.
Fiat pulvis.
S. To be taken in a wineglassful of sweetened water.
An active emetic in narcotic poisoning, etc.

℞ Pulveris Jalapæ gr. x.
Potassii Bitartratis ʒii.
Misce.
S. To be taken in syrup or molasses.
A hydragogue cathartic, used in dropsy, and in scrofulous inflammation of the joints.

℞ Sulphuris ʒi.
Potassii Bitartratis ʒii.
Misce.
S. To be taken in syrup or molasses.
A laxative used in piles and cutaneous diseases.

℞ Pulveris Rhei gr. x.
Magnesiæ ʒss.
Fiat pulvis.
S. To be taken in syrup or molasses.
A laxative and antacid, used in diarrhœa, dyspepsia, etc.

℞ Potassii Nitratis ʒi.
Antimonii et Potassii Tartratis gr. i.
Hydrargyri Chloridi Mitis gr. vi.
Fiat pulvis, in chartulas sex dividendus.
S. One to be taken every two hours in syrup or molasses.
A refrigerant, diaphoretic, and alterative, used in bilious fevers; usually called *nitrous powders.*

℞ Pulveris Calumbæ,
Pulveris Zingiberis, āā, ʒi.
Fiat pulvis, in chartulas sex dividendus.
S. One to be taken three times a day in syrup or molasses.
A tonic, used in dyspepsia.

Pills.

℞ Pulveris Aloes,
Pulveris Rhei, āā, ʒss.
Olei Caryophylli gtt. x.
Saponis ℈i.
Misce, et cum aquâ fiat massa in pilulas viginti dividenda.
S. Two or three to be taken daily, at bedtime, or before a meal.
An excellent laxative in habitual constipation.

℞ Pulveris Aloes,
Extracti Quassiæ, āā, ʒi.
Olei Anisi ♏x.
Syrupi q. s.
Misce, et fiat massa in pilulas triginta dividenda.
S. Two to be taken once, twice, or three times a day.
A laxative, tonic, and carminative, useful in dyspepsia.

℞ Pulveris Scillæ ℈i.
Hydrargyri Chloridi Mitis gr. x.
Pulveris Acaciæ,
Syrupi, āā, q. s.
Misce, et fiat massa in pilulas decem dividenda.
S. One to be taken twice or three times a day.
A diuretic and alterative, much used in dropsy, especially when complicated with organic visceral disease.

℞ Plumbi Acetatis, in pulv. triti, gr. xii.
Pulveris Opii gr. i.
Pulveris Acaciæ,
Syrupi, āā, q. s. ut fiat massa in pilulas sex dividenda.
S. One every two, three, or four hours.
An astringent much employed in hæmoptysis and uterine hemorrhage.

Mixtures.

℞ Magnesiæ ʒi.
Syrupi fʒi.
Tere simul, et affunde
Aquæ Acidi Carbonici fʒiv.
Fiat haustus.
S. To be taken at a draught, the mixture being well shaken.
An agreeable magnesia mixture.

℞ Mannæ ʒi.
Fœniculi contusi ʒi.
Aquæ bullientis fʒiv.
Fiat infusum et cola; dein adjice.
Magnesii Carbonatis ʒii.
Ft. mist.
S. One-third to be taken every three or four hours till it operates.

℞ Olei Ricini fʒiss.
Tincturæ Opii ♏xxx.
Pulveris Acaciæ,
Sacchari, āā, ʒii.
Aquæ Menthæ Viridis fʒiv.
Acaciam et saccharum cum paululo aquæ menthæ tere; dein oleum adjice, et iterum tere; denique aquam reliquam paulatim infunde, et omnia misce.
S. A tablespoonful to be taken every hour or two hours till it operates.
Used as a gentle laxative in dysentery and diarrhœa. It is usually known by the name of *oleaginous mixture.*

℞ Acidi Nitrosi fʒi.
Tincturæ Opii gtt. xl.
Aquæ Camphoræ fʒviii.
Misce.
S. One-fourth to be taken every three or four hours.
Hope's camphor mixture, used in dysentery, diarrhœa, and cholera.

Effervescing Draught.

℞ Potassii Carbonatis ʒii.
Aquæ fʒiv.
Liqua.
Or,

℞ Potassii Bicarbonatis ʒiii.
Aquæ fʒiv.
Liqua.
S. Add a tablespoonful of the solution to the same quantity of lemon or lime juice, previously mixed with a tablespoonful of water; and give the mixture in the state of effervescence, every hour or two hours.
An excellent diaphoretic and anti-emetic in fever with nausea or vomiting. If morphine is needed, it should be dissolved in the lemon-juice. It is precipitated from alkaline solutions.

Solutions.

℞ Magnesii Sulphatis ʒi.
Syrupi Limonis fʒi.
Aquæ Acidi Carbonici fʒvi.
Misce.
S. To be taken at a draught.
An agreeable mode of administering magnesium sulphate.

℞ Quininæ Sulphatis gr. xii.
Acidi Sulphurici Aromatici gtt. xxiv.
Syrupi fʒss.
Aquæ Menthæ Piperitæ fʒi.
Misce.
S. A teaspoonful to be taken every hour or two hours.
A good mode of administering sulphate of quinine in solution.

Infusions.

℞ Sennæ ʒiii.
Magnesii Sulphatis,
Mannæ, āā, ℥ss.
Fœniculi ʒi.
Aquæ bullientis Oss.
Macera per horam in vase leviter clauso, et cola.
S. A teacupful to be taken every four or five hours till it operates.
An excellent purgative in febrile complaints.

℞ Calumbæ contusæ,
Zingiberis contusi, āā, ℥ss.
Sennæ ʒii.
Aquæ bullientis Oi.
Macera per horam in vase leviter clauso, et cola.
S. A wineglassful to be taken morning, noon, and evening, or less frequently if it operates too much.
An excellent remedy in dyspepsia with constipation and flatulence.

METRIC PRESCRIPTIONS.

Of late years, since the more general use of the metric system, prescriptions written according to this method have been frequently employed, especially in sections of our country inhabited by those who are accustomed to use the system, which is now almost exclusively employed in Europe. For an explanation of its principles the reader is referred to the article on weights and measures, page 1874. Two distinct methods are in vogue in the United States, called respectively *gravimetric* and *volumetric;* in the *gravimetric* plan, which is almost exclusively used abroad, no *measures* of capacity are employed, weights being alone used; the unit of weight, the *gramme*, and its subdivisions constituting the sole weights. This method is objected to by many, who are habituated to the usual American practice of measuring instead of weighing liquids, and the *volumetric* method, in which liquids are measured, is preferred, the unit of measure selected being the *cubic centimeter* (abbreviated C.c., and sometimes called *fluigramme*),

which is equivalent to a gramme of water at 4° C. One of the principal arguments in favor of the volumetric method is that no plan has yet been devised by which the patient can take the dose by weight; teaspoons, tablespoons, or graduated glasses are used altogether for administering liquid medicines, and it would be an almost impracticable task for the practitioner to bear constantly in mind the difference in specific gravity between chloroform, ether, glycerin, syrups, water, and other liquids, yet this would be absolutely necessary in order to secure accurate dosage if the gravimetric method were adopted; and in addition the pharmacist would be compelled to weigh the liquids in compounding prescriptions, a troublesome innovation, or to calculate the corresponding volume of each liquid if graduated measures were used. Arabic numerals are exclusively employed in metric formulæ, arranged in a column opposite the names of the ingredients of the prescription: this custom should never be deviated from, as it is one of the means of recognizing metric prescriptions. The following examples will illustrate the various forms of metric prescriptions in general use, but it is very important that but *one* of these forms should be adopted and *adhered to* if the merits of the system are to be fully realized. We decidedly prefer form Number 1.

PILLS.

Form Number 1.

	Gramma.
℞ Pulv. Aloes	2
Pulv. Rhei	1·5
Olei Caryophylli	·6
Saponis	1·25

Make twenty pills.

The advantages of the decimal line are that the decimal dot is abolished with its dangerous complications, for a spot or a fly-speck on the prescription paper may increase or decrease the quantity of an ingredient *ten times*, and the use of the decimal line is familiar to all who use a dollar and cents column.

Form Number 2.

℞ Pulv. Aloes	2·
Pulv. Rhei	1·5
Olei Caryophylli	·6
Saponis	1·25

Make twenty pills.

This form is used frequently, because of the familiarity with the arithmetical method of using a dot to denote a decimal fraction; and where metric prescriptions are altogether in use, as in Continental Europe, there is no necessity for indicating the denomination, gramme being always understood.

Form Number 3.

℞ Pulv. Aloes	2	Gm.
Pulv. Rhei	1·5	Gm.
Olei Caryophylli	·6	Gm.
Saponis	1·25	Gm.

Make twenty pills.

This form is an improvement on Number 2, and would be far superior to it for use in this country, where prescriptions written in the old systems will long continue to be used; for next to writing out in full the word *gramme*, the indication of the unusual quantity by underscoring will prevent its being mistaken for *grain*.

LIQUIDS.

Form Number 1.

(*Volumetric.*)

	Gm. C.c.
℞ Magnesiæ Sulph.	30
Acid. Sulph. Dil.	6
Syrup. Limonis	30
Aquæ	180

Make a draught.

Form Number 2.

(*Gravimetric.*)

℞ Magnesiæ Sulph.	30·
Acid. Sulph. Dil.	·6
Syrup. Limonis	30·
Aquæ	180·

Make a draught.

Form Number 3.

(*Volumetric.*)

℞ Magnesiæ Sulph.	30	Gm.
Acid. Sulph. Dil.	·6	C.c.
Syrup. Limonis	30	C.c.
Aquæ	180	C.c.

Make a draught.

TABLES OF WEIGHTS AND MEASURES.

APOTHECARIES' WEIGHT. *U. S.*

Pound.		Troyounces.		Drachms.		Scruples.		Troy Grains.
℔ 1	=	12	=	96	=	288	=	5760
		℥ 1	=	8	=	24	=	480
				ʒ 1	=	3	=	60
						℈ 1	=	gr. 20

The Imperial Standard Troy weight, at present recognized by the British laws, corresponds with the Apothecaries' weight in pounds, ounces, and grains; but differs from it in the division of the ounce, which, according to the former scale, contains twenty pennyweights, each weighing twenty-four grains.

AVOIRDUPOIS WEIGHT. *Br.*

Pound.		Ounces.		Drachms.		Troy Grains.
℔ 1	=	16	=	256	=	7000
		oz. 1	=	16	=	437·5
				dr. 1	=	gr. 27·34375

Relative Value of Troy and Avoirdupois Weights.

Pound.		Pounds.		Pound.	Ounces.	Grains.
1 Troy	=	0·822857	Avoirdupois =	0	13	72·5
1 Avoirdupois	=	1·215277	Troy =	1	2	280

APOTHECARIES' OR WINE MEASURE. *U. S.*

Gallon.		Pints.		Fluidounces.		Fluidrachms.		Minims.		Cubic Inches.

* Dr. W. H. Pile, in a communication to the *American Journal of Pharmacy*, gives the following weights of the fluidounce of water, on different authorities, at 60° F.: United States standard 455·6216 grains; Sir G. Shuckburg (U.S.D.) 455·6944; British standard 455·6910; average weight 455·6690.

In converting the weights of liquids heavier or lighter than water into measures, or conversely, a correction must be made for specific gravity. In converting weights into measures, the calculator may proceed as if the liquid was water, and the obtained measure will be to the true measure *inversely* as the specific gravity. In the converse operation, of turning measures into weights, the same assumption may be made, and the obtained weight will be to the true weight *directly* as the specific gravity.

METRIC WEIGHTS AND MEASURES.

The French *metrical* system is based upon the idea of employing, as the unit of all measures, whether of length, capacity, or weight, a uniform unchangeable standard, adopted from nature, the multiples and subdivisions of which should follow in decimal progression. To obtain such a standard, the length of one-fourth part of the terrestrial meridian, extending from the equator to the pole, was ascertained. The ten-millionth part of this arc was chosen as the unit of measures of length, and was denominated *meter*.* The cube of the tenth part of the meter was taken as the unit of measures of capacity, and denominated *liter*. The weight of distilled water, at its greatest density, which this cube is capable of containing, was called *kilogramme*, of which the thousandth part was adopted as the unit of weight, under the name of *gramme*. The multiples of these measures, proceeding in the decimal progression, are distinguished by employing the prefixes *deca*,† *hecto*, *kilo*, and *myria*, taken from the Greek numerals; and the subdivisions, following the same order, by *deci*, *centi*, *milli*, from the Latin numerals. Since the introduction of this system it has been adopted by the principal nations of Europe, excepting Great Britain, and in many of them its use is compulsory. It is in general use in France, Germany, Austria-Hungary, Italy, Spain, Norway, Sweden, Netherlands, Switzerland, Greece, and British India. It was legalized in Great Britain in 1864, and in the United States by an act of Congress in 1866.

The *meter*, or unit of length, at 32°,	=	39·370432 inches.
The *liter*, or unit of capacity,	=	33·814 fluidounces. *U. S.*
The *gramme*, or unit of weight,	=	15·43234874 Troy grains.

Upon this basis the following tables have been constructed.

Measures of Length.

		English Inches.		Miles.	Rods.	Yards.	Feet.	Inches.
Millimeter (mm.)	=	·03937						
Centimeter (cm.)	=	·39370						
Decimeter (dm.)	=	3·93704						
Meter (m.)	=	39·37043	=	0	0	1	0	3·370

Myriagramme (Mg.)	=	154323·4874	=	26	9	4	8·4

* There are two methods of spelling the metric units in common use, one, the original, *metre*, *litre*, *gramme*; in the other, these are spelled *meter*, *liter*, and *gram*. The U. S. Pharmacopœia of 1890 sanctions both methods, which, in our opinion, is unfortunate. *Metre* and *litre* are spelled meter and liter, whilst the original orthography is retained for *gramme*.

† Deca and hecto are sometimes written deka and hekto.

Value of Avoirdupois Weights and Imperial Measures, in Metrical Weights and Measures, as stated in the British Pharmacopœia.

APPROXIMATE MEASUREMENT.

For the sake of convenience, in the absence of proper instruments, we often make use of means of measurement which, though not precise nor uniform, afford results sufficiently accurate for ordinary purposes. Of this kind are certain household implements, of a capacity approaching to uniformity, and corresponding to a certain extent with the regular standard measures. Custom has attached a fixed value to these implements, with which it is proper that the practitioner should be familiar; although their capacity, as they are now made, with the exception of the wineglass, generally somewhat exceeds that at which they were originally and still continue to be estimated.

A *tea-cup* is estimated to contain about four fluidounces, or a gill.
A *wineglass* . . . . . two fluidounces.
A *tablespoon* (cochlear magnum) . . half a fluidounce.
A *teaspoon* (cochlear parvum) . . . a fluidrachm.

In reading French medical works, if unacquainted with their customary expressions of measure, we are often left in great uncertainty as to the precise quantity indicated by the names. The following table, translated from the French Codex of 1866, will obviate this difficulty. (See Metric Table, page 1874.)

	Grammes.
A coffeespoon (*cuillerée à café*, Fr., *teaspoon*)	5
A common spoon (*cuillerée*, Fr., *tablespoon*), 4 coffeespoons, or	20
A glass (*verre*, Fr.), 8 common spoons	160
A handful (*poignée*, Fr.) of barleyseed	80
" " " flaxseed	50
" " " flaxseed-meal	150
" " " dried mallow leaves	40
" " " " chicory "	30
A pinch (*pincée*, Fr.) of chamomile flowers	2
" " " arnica "	1
" " " marshmallow "	2
" " " mallows "	1
" " " linden "	2
" " " fruits of anise	2
" " " " fennel	2
A hen's egg, newly laid, has the mean weight of	64
" the white alone	40
" the yellow alone	20
Blanched almonds have the mean weight, each, of	1

Small quantities of liquid medicines are often administered by *drops*, each of which is usually considered equivalent to a minim, or the sixtieth part of a fluidrachm. The drop of water and of watery fluids is, sometimes, about that size; but the same is by no means the case with all medicinal liquids, and the drop even of the same liquid varies much in bulk, according to the circumstances under which it is formed. This is, therefore, an uncertain mode of estimating the quantity of liquids, and should be superseded where minim measures can be had. Certain rules, however, influence the formation of drops, which will enable us to form some notion of their probable relative number, in the same amount of liquid, when possessed of the requisite data. Thus, the heavier the liquid, the smaller, other things being equal, is the size of the drops, and the greater their number in a given measure. The drop of chloroform, for example, which is a very heavy liquid, is very small, much smaller than that of alcohol or ether. The greater or less viscidity and greater or less mobility of the liquid have much influence, the former in increasing, the latter in diminishing the size of the drops. The adhesiveness of liquids, which opposes their disposition to leave the surface from which they fall, requires a greater mass to overcome it, and consequently augments the size of the drop. The rapidity of the movement acts in a contrary direction, and the drop from a full bottle should be less than from one more or less emptied. The broader the surface from which they fall, the greater is their size. The drops from a thick-lipped bottle are larger than from one with thin lips.

The results stated in the following table were obtained by Mr. Stephen L. Talbot. They may be relied on as accurate, and in most cases correspond with the results obtained by Mr. Durand and Prof. Procter (see *A. J. P.*, i. 169; 1865, p. 389; 1880, p. 337), but should be considered as indicating only the relative number of drops afforded by the several liquids mentioned; for, under other circumstances than those of Mr. Talbot's experiments, entirely different results might be obtained as relates to each liquid. The preparations experimented with were those of the U. S. Pharmacopœia of 1870.

TABLES SHOWING SPECIFIC GRAVITY CORRESPONDING WITH DEGREES OF HYDROMETERS.

Baumé's hydrometer is usually employed. In this instrument the specific gravity of distilled water is assumed as the zero of the descending scale in relation to fluids heavier than itself, and as ten on the ascending scale in relation to lighter fluids. In the following tables the specific gravity of liquids is given corresponding with the several degrees of this hydrometer. The first column of specific gravities is taken from the French Codex. The second column is based on the calculations of Huss. The third column was calculated by Mr. Henry Pemberton, of Philadelphia, in 1851. The figures in this column correspond with the degrees of the hydrometers prepared by the late Dr. W. H. Pile.

For Liquids Lighter than Water.

The following formulas, furnished by Dr. Pile, may prove useful by enabling any one to calculate the sp. gr. corresponding with the several degrees of Baumé's hydrometer, and, conversely, the degree of Baumé corresponding with the sp. gr.

1. *For Liquids lighter than Water.* The following formulas give the sp. gr. as represented in the first column in the foregoing table; or, the specific gravity being known, give the corresponding degree of Baumé.

$$\frac{144}{B°+134} = \text{sp. gr.}; \text{ and } \frac{144}{\text{sp. gr.}} - 134 = B°.$$

The following formulas apply to the third column of specific gravities.

$$\frac{140}{B°+130} = \text{sp. gr.}; \text{ and } \frac{140}{\text{sp. gr.}} - 130 = B°.$$

2. *For Liquids heavier than Water.* For the first column, $\frac{144}{144-B°} = \text{sp. gr.}$, and $144 - \frac{144}{\text{sp. gr.}} = B°$; for the third, $\frac{145}{145-B°} = \text{sp. gr.}$, and $145 - \frac{145}{\text{sp. gr.}} = B°$.

For Liquids Heavier than Water.

Gay-Lussac's centesimal alcoholmeter is applicable only to alcohol. The scale of this instrument is divided into 100 unequal degrees, the zero corresponding to pure water, and 100° to absolute alcohol; and every intermediate degree expresses the percentage of pure alcohol, by measure, contained in the liquors examined. Thus, when the instrument stands at 40° in any alcoholic liquid, it indicates that 100 measures of the liquid contain 40 of pure alcohol and 60 of water. But, as it was graduated for the temperature of 59° of Fahrenheit, the liquors to be tested should be brought to that temperature. *Tralles's centesimal alcoholmeter* is the one used by the U. S. Government in gauging the strength of spirit, and is generally employed in this country by distillers and wholesale dealers in the purchase and sale of alcoholic liquors. The scale of this instrument is, like Gay-Lussac's, divided into 100 unequal parts, each corresponding to the percentage by volume of pure alcohol contained in the liquors examined. As the sp. gr. of water is considered as unity at its temperature of greatest density, 39·8° F., and the degrees of this scale are calculated for 60° F., the zero, corresponding to the density of water, will represent a sp. gr. of ·9991.

The following table of Tralles gives the percentage of alcohol *by measure* corresponding with the specific gravity. Under "Alcohol," in the first part of this work, a table of the percentage by weight cor-

responding with the sp. gr. is given. By means of these tables, in connection with the alcoholmeter, every problem that can arise in reference to the strength of spirituous liquors can be solved; and by the appended table, giving the value of Baumé's degrees in those of Tralles, the facility is still further extended.

Alcoholmetrical Table of Tralles.

Alcohol in 100 measures of spirit.	Specific gravity at 60° F.	Alcohol in 100 measures of spirit.	Specific gravity at 60° F.	Alcohol in 100 measures of spirit.	Specific gravity at 60° F.	Alcohol in 100 measures of spirit.	Specific gravity at 60° F.

RELATIONS BETWEEN THERMOMETERS.

In *Fahrenheit's* thermometer, the freezing point of water is placed at 32°, and the boiling point at 212°, and the number of intervening degrees is 180.

The *Centigrade* or *Celsius's* thermometer, which is now recognized in the U. S. Pharmacopœia and has been adopted generally by scientists, marks the freezing point *zero*, and the boiling point 100°.

In *Réaumur's* thermometer the freezing point is at *zero*, and the boiling point at 80°.

In *De Lisle's* thermometer, used in Russia, the graduation begins at the boiling point, which is marked *zero*, while the freezing point is placed at 150°.

From the above statement, it is evident that 180 degrees of Fahrenheit are equal to 100° of the Centigrade, 80° of Réaumur, and 150° of De Lisle; or 1 degree of the first is equal to $\frac{5}{9}$ of a degree of the second, $\frac{4}{9}$ of a degree of the third, and $\frac{5}{6}$ of a degree of the last. It is easy, therefore, to convert the degrees of one into the equivalent number of degrees of the other; but in ascertaining the corresponding points upon the different scales, it is necessary to take into consideration their different modes of graduation. Thus, as the zero of Fahrenheit is 32° below the point at which that of the Centigrade and of Réaumur is placed, this number must be taken into account in the calculation.

1. If any degree on the *Centigrade* scale, either above or below zero, be multiplied by 1·8, the result will, in either case, be the number of degrees above or below 32°, or the freezing point of *Fahrenheit*.

2. The number of degrees between any point of *Fahrenheit's* scale and 32°, if divided by 1·8, will give the corresponding point on the *Centigrade*.

THERMOMETRIC EQUIVALENTS.

According to the Centigrade and Fahrenheit Scales.

ALCOHOL.

According to E. R. Squibb.

PART I.—From 0 to 10 per cent. of Absolute Alcohol.

Specific Gravity. (Pure water at 15⅝° C. = 60° F. taken as unity.)		Percentage.				Weight of one gallon, at 15⅝° C. = 60° F.							Weight of 40 gallons to the nearest half pound, at 15⅝° C. = 60° F.	Weight of one pint, at 15⅝° C. = 60° F.	
								Avoirdupois Weight.							
											To the nearest ounce.				
At 15⅝° C. = 60° F.	At 25° C. = 77° F.	By weight.	By volume.	Under proof (Brit. Excise.)	Of proof spirit. (U. S. Revenue.)	In Grammes.	In Grains.	lbs.	ozs.	Grs.	lbs.	ozs.	lbs.	In Grammes.	In Grains.

ALPHABETICAL TABLE OF FORMULAS AND MOLECULAR WEIGHTS.

Note.—The Roman numerals after the symbols of elements represent their *equivalence*, or combining value referred to hydrogen as unity.

Name.	Symbol or Formula.	Atomic or Molecular Weight.
Acetal	$C_6H_{14}O_2$	117·74
Acetanilid	$C_6H_5NH.C_2H_3O$	134·73
Acetic Ether	$C_2H_5.C_2H_3O_2$	87·80
Acetone	C_3H_6O	57·87
Acetophenone (hypnone)	C_8H_8O	119·72
Acid, Acetic	$HC_2H_3O_2$	59·86
" Antimonic	H_3SbO_4	186·44
" Antimonous	H_3SbO_3	170·48
" Arsenic	H_3AsO_4	141·74
" Arsenous. See also Arsenous Oxide	H_3AsO_3	125·78
" Aurochloric	$HAuCl_4 + 2H_2O$	375·10
" Benzoic	$HC_7H_5O_2$	121·71
" Boric	H_3BO_3	61·78
" Camphoric	$H_2C_{10}H_{14}O_4$	199·54
" Carbolic	$C_6H_5.OH$	93·78
" Carbonic. See also Carbon Dioxide	H_2CO_3	61·85
" Chloroplatinic	$H_2PtCl_6 + 6H_2O$	516·28
" Chromic. See Chromium Trioxide.		
" Cinnamic	$HC_9H_7O_2$	147·65
" Citric	$H_3C_6H_5O_7 + H_2O$	209·50
" Cyanic	$HCNO$	42·94
" Gallic	$HC_7H_5O_5 + H_2O$	187·55
" Glycerino-Phosphoric	$H_2C_3H_7O_6P$	171·63
" Hydriodic	HI	127·53
" Hydrobromic	HBr	80·76
" Hydrochloric	HCl	36·37
" Hydrocyanic	HCN	26·98
" Hydrofluoric	HF	20·00
" Hydrosulphuric. See Hydrogen Sulphide.		
" Hypophosphorous	HPH_2O_2	65·88
" Kinic (quinic)	$HC_7H_{11}O_6$	191·55
" Lactic	$HC_3H_5O_3$	89·79
" Meconic	$C_7H_4O_7$	199·51
" Metaphosphoric	HPO_3	79·84
" Molybdic. See Molybdic Oxide.		
" Nitric	HNO_3	62·89
" Nitrous	HNO_2	46·93
" Oleic	$HC_{18}H_{33}O_2$	281·38
" Oxalic	$H_2C_2O_4 + 2H_2O$	125·70
" Oxalic (dry)	$H_2C_2O_4$	89·78
" Palmitic	$HC_{16}H_{31}O_2$	255·44
" Phosphoric	H_3PO_4	97·80
" Phosphorous	H_2PHO_3	81·84
" Picric	$C_6H_2(NO_2)_3OH$	228·57
" Prussic. See Acid, Hydrocyanic.		
" Pyroboric	$H_2B_4O_7$	157·32
" Pyrophosphoric	$H_4P_2O_7$	177·64
" Salicylic	$HC_7H_5O_3$	137·67
" Silicic. See also Silicic Oxide	H_2SiO_3	78·18
" Stearic	$HC_{18}H_{35}O_2$	283·38

Acid, Succinic	$H_2C_4H_4O_4$	117·72
" Sulphuric	H_2SO_4	97·82
" Sulphurous	H_2SO_3	81·86
" Tannic	$C_{14}H_{10}O_9$	321·22
" Tartaric	$H_2C_4H_4O_6$	149·64
" Titanic. See Titanic Oxide.		
" Trichloracetic	$HC_2Cl_3O_2$	162·97
" Tungstic. See Tungstic Oxide		
" Uric	$C_5H_4N_4O_3$	167·77
" Valerianic	$HC_5H_9O_2$	101·77
Aconitine	$C_{33}H_{43}NO_{12}$	643·54
Alcohol, Amylic	$C_5H_{11}.OH$	87·81
" Ethylic	$C_2H_5.OH$	45·90
" Methylic	$CH_3.OH$	31·93
Aldehyde, Acetic	C_2H_4O	43·90
" Formic	$CHO.H$	29·93
Alum (Potash-Alum)	$Al_2(SO_4)_3 + K_2SO_4 + 24H_2O$	946·46
" (dried)	$Al_2(SO_4)_3 + K_2SO_4$	515·42
Aluminum	Al $[(Al_2)^{VI}]$	27·04
